I. Manton (Great Britain) urged that "The Concept of the Aggregate Species" should be used in floras, illustrating her remarks by reference to her work on *Polypodium*. The aggregate species *P. vulgare* is composed of *P. australe*, $2n$ chromosomes with a genotypic composition one might call B; *P. vulgare* s.s., $4n$ chromosomes with a genotype AC; and *P. interjectum*, $6n$ chromosomes with a genotype ABC. A second aggregate species would be *P. virginicum* with a microspecies with $2n$ (genotype A), and another with $4n$ (genotype AD).

R. C. Rollins (United States) in "Some Considerations of the Comparative Systematics of Vascular Plant Species" stressed the importance of comparative systematics in flowering plants, emphasizing that no single set of principles covers all the different types of variation which are encountered even within relatively narrow alliances. He instanced two genera of Cruciferae, *Lesquerella* and *Leavenworthia*, each with four species, having a striking parallel distribution in Tennessee. The variation pattern in these two genera, annuals occupying open habitats, is totally different. In *Lesquerella* the species are vicarious, and when artificially brought together, freely form hybrids, indicating the total lack of genetical sterility barriers. In *Leavenworthia* the species are sympatric, and highly incompatible with each other.

C. G. G. J. van Steenis (Holland) spoke on "Specific Delimitation, with Special Reference to Tropical Plants". He reviewed how far modern detailed research in genetics, experimental morphology, karyology and biochemistry has affected the basic value of the Linnean species. Though there is greatly increased insight of intraspecific structure the Linnean concept has been confirmed and has lost nothing of its actuality. The delimitation of genera and species is still the keystone of taxonomy, affecting botany in all its branches—pure and applied. From various points of view it is most unfortunate that botanical science in general, and taxonomy in particular, were not developed in the tropics instead of in countries with depauperated floras and disturbed vegetation. Systematists investigating tropical floras are concerned at the immense flow of experimental research which, while tending to undermine the species concept, simultaneously introduces 'characters' and delimitations which the systematist can neither test nor judge on their intrinsic merits.

W. Ludwig (Western Germany) then gave a paper "Artbegriff und Evolution der Art unter dem Aspect E. Geoffroys (Geoffroyismus)".

The next morning's session began with J. Clausen (United States) on "Function and Evolution of Ecotypes, Ecospecies and other Natural Entities". Genetic-ecologic experiments have shown that morphological and ecological characters that adjust ecological races to the environment are governed by fairly complex systems of genes composed of genes of the multiple kind which may have additive, subtractive, complementary, or epistatic effects in various proportions. The genes that regulate the individual character are usually located on different chromosomes, enabling fairly free recombination. They are distributed to the ecological races of a species in such a manner that one race may possess the genetic key that unlocks the heredity that is stored in another race. Interracial crossing accordingly results in the release of variability, in transgressive segregation, and in hybrid vigour.

Some of the genes that regulate different characters, however, are located on the same chromosomes, and accordingly cause moderate genetic linkage between distinguishing characters. The linkage is loose because only some of the genes of the system are linked. Such a genetic structure causes moderate genetic coherence, and permits moderate genetic recombination between ecological races. Ecological races, morphological subspecies, and closely related species function, therefore, as gene pools that store the potential variability of the genus in recognizable evolutionary entities or taxa, dynamic and flexible. Their genes regulate balanced processes adjusted to the seasonal and diurnal rhythms of the environment, an adjustment delicately balanced and requiring generations for development. A moderate genetic coherence is therefore an evolutionary necessity for proper survival. Natural selection has accordingly favoured such entities that possessed genetic structures sufficiently rigid to reproduce themselves as long as the environment remained essentially the same and that were sufficiently flexible to permit them to change in periods of geologic revolution.

W. B. Turrill (Great Britain) then considered "Genetic Variation within Taxonomic Species", taking most of his illustrations from *Silene maritima* and *S. vulgaris*. He emphasized the importance of habit characters as separating ecologically the two species and sub-species within them. Some of the variations experimentally proved to be genetical were definitely of survival value, others were deleterious, and others were doubtfully of survival value under the conditions now favoured by the different taxa. Some of the characters appear to be neutral in the sense of producing more or less balanced polymorphisms in many populations. The importance of considering the phenotype as a whole should always be kept in mind when survival value is being investigated.

J. Heslop Harrison (Northern Ireland) followed with "Ecological Variation and Ethological Isolation". Since the breeding system in a plant species is a dominant factor in determining its capacity for race formation, it is to be expected that differences will be found between anemophilous and entomophilous species in their patterns of infra-specific variation. In species which are specialized for a limited range of pollinators, persistent assortative pollination ('homogamy') in populations polymorphic for flower characteristics could provide the conditions for sympatric race formation, and this may have particular importance when it is accompanied by simultaneous ecological differentiation. Examples which appear to illustrate this are to be found among the European Orchidaceae, in several species of which ecological races exist that differ from each other morphologically only in the allaesthetic features of the flowers.

Z. Lorković (Yugoslavia) spoke on "Die Merkmale der unvollendteten Speziationsstufe und die Frage der Einführung der Kathegorie der Semispezies in die Systematik". In the newer especially experimental systematics it is becoming increasingly common to find that two populations can be classified either as true species or as races, and that in one of them at least the inner reproductive isolation mechanism is not fully developed. He proposed, therefore, to denote such an incomplete degree in speciation as a new taxon, semispecies or prospecies. Otherwise there is the danger of concluding that species and race mix, which must lead not only to faulty systematics but also to false evolutionary inferences.

F. A. Schilder (Eastern Germany) followed with "Versuch einer genetischen Klassification der Varianten bei Bänderschnecken". In the garden snail (*Cepaea hortensis*) variations in the shells are enormous, but there are great differences in frequency according to the presence or absence of certain genes in the populations. Though most varieties have been named scientifically, it seems to be more useful to design the characters of each specimen by a series of letters indicating its hereditary features in colour, banding, size, etc. When describing a population, the unit in biological evolution, one should indicate the percentage of varieties observed with regard to each independent character. The frequency of characters decreases concentrically from the locality where a character has been changed by mutation, and there seems to be scarcely any influence of environment on the progress of its distribution.

F. Ehrendorfer (Austria) in "Die geographische und okologische Entfaltung des europäisch-alpinen Polyploidenkomplexes *Galium anisophyllum* Vill. seit Beginn des Quartärs" dealt with his cytogenetical and field-study research on this species. He stated that there were various polyploids (2, 4, 6, 8, 10-ploids) within the so-called species and related them to present-day ecological conditions and to those during and since the Glacial Epoch, and concluded that polyploids with the same chromosome number can arise in different ways.

B. Lövkvist (Sweden) dealt with the *Cardamine pratensis* complex in "Polyploidy and Ecological Differentiation". Chromosome numbers in pure-breeding populations range from 16 to 96 and the cultivated material can be divided into two morphological groups: the Temperate Group in which all the numbers occur, and the Arctic Group with only the numbers 64 and 80.

The components of the *C. pratensis* complex are ecologically well isolated from most other *Cardamine* species. New plants of all groups of the complex are self-incompatible. Therefore if only a few immigrants grow in a locality the number of self-incompatible alleles need be quite small. As hybrids are completely fertile hybrid swarms arise.

Field studies in south Sweden showed that populations with different chromosome numbers have different ecological preferences. High water-content of soil is the main adaptation factor: another is the biotic factor of competition. Vegetative reproduction is widespread so that it is necessary to decide whether plants growing in a special niche belong to a clone or constitute a population.

The last paper of the session was "The Taxonomic Treatment of Vicarious Taxa" by O. Hedberg (Sweden). The gradual differentiation of one species population into two or more independent taxa is a very complicated process. It seems well established that the rate of evolution may be greater in some features than in others. Thus the degree of genetical isolation between two closely related taxa is not always proportional to the amount of differentiation in gross morphology, chromosome make-up, etc. It is therefore dangerous to rely upon genetical isolation as an unfailing criterion for specific distinction. Though experimental methods are greatly aiding our understanding of many points in evolution they cannot be applied within the foreseeable future to more than a fraction of species described, and so to be able to write consistent accounts of floras we are compelled to retain the traditional taxonomic hierarchy.

When closely related taxa inhabit mutually exclusive areas the sole criterion for taxonomic distinction is the occurrence of discontinuous morphological variation. The taxonomic treatment of such 'geographically vicarious' taxa may often offer considerable difficulties.

Good examples are provided by the floras of the high East African mountains where the alpine biotas are completely isolated. Within several genera examples occur where the populations of different mountains are taxonomically distinguishable, forming groups of vicarious taxa. Recent studies have revealed numerous intermediate types which are difficult to classify. Some species occur in isolated populations on many or all of the mountains with no perceptible morphological differentiation; in others, different mountain populations of one species show statistical differences, but their variation-ranges overlap so as to make taxonomic distinction impossible; whereas in others there are distinctly discontinuous variation-ranges in one or more features. As a working rule the author chose to demand clearly discontinuous variation in at least two independent characters for specific distinction, and one clear discontinuity for subspecific. But numerous intermediate stages of differentiation exist.

The last session began with a short account by J. Ramsbottom (Great Britain) of the precautions taken by the Linnean Society of London and by the British Museum (Natural History) for the protection of Linnaeus's collections during the Second World War.

F. Widder (Austria) then spoke on "Die geographisch-morphologische Methode als abgestufter Verwandtshaftstest".

H. Merxmüller (Western Germany) followed with "Einige Probleme der Sippengliederung und Arealbildung in den Alpen", in which he considered the so-called 'Tischler's rule' that in the flora of a given region there is a constantly increasing proportion of polyploids from south towards north. He gave reasons for holding that Tischler's rule must be restricted to two types of region—mountainous areas where the various biotypes widely separated in the plains come closely together, and regions strongly sculptured during the glacial epoch where different wandering floras could meet. It should, therefore, apply to the Alps, but many Swiss authors have concluded otherwise. The author thinks the discrepancy can be explained by regarding the heavily glacier-worn Central Alps and the bordering regions which were not glaciated, where old floras often of Mediterranean or Asiatic origin have been conserved, and often succeeded in re-entering the blanks left by the receding ice. This very considerable portion of old prediluvial types in the present alpine flora interferes with statistical results. The apparent failure of the rule is explained by the fact that the percentage of polyploids in the Alps has been compared with that of the regions north of them in Central Europe instead of the regions south, east and west, which were only slightly disturbed in the glacial period.

J. Iversen (Denmark) discussed "The Bearing of the Glacial and Interglacial Epochs on the Formation and Extinction of Plant Taxa". Conditions that favour the formation, or, reversely, the extinction, of plant species differed greatly in the course of one great cycle of glacial and postglacial (interglacial) succession. The period of maximum cold (full glacial) appears to have been purely destructive. The following stage was constructive, due to rising temperature combined with slight competition only; light was adequate, the immature soil basic or neutral. Later, optimal temperature and soil conditions favoured dense forest growth; shade-intolerant species were suppressed or became rare relics. In the last stage the destruction of the flora was accelerated by climatic decline and soil degradation. Agriculture greatly modified this course, which applies to north-western Europe specifically.

G. E. Du Rietz (Sweden) speaking on "The Hybrid Concept" and illustrating his remarks with particular reference to New Zealand was concerned mainly with the nomenclature of what are generally known as hybrid swarms.

B. Petersen (Sweden) demonstrated "*Pieris napi* and *P. bryoniae*, two 'Siamese twin species' ". These species are sympatric in the Alps and in the Carpathians. In Scandinavia similar forms are allopatric and connected by geoclines. Common descent and not reproductive communication should in such a case be decisive for the taxonomic treatment of the group.

G. Svärdson (Sweden) continued the Swedish contributions with "Interspecific Hybrid Populations in *Coregonus*". The morphological and ecological variation is great. The variation, however, is mostly environmental and only partly genetical. Therefore, to establish a firm basis for the study of speciation in this fish group, some characters must be found which are genetically determined and have only a low capacity for environmental modification. Experiments still in progress were begun in 1944. Special attention was paid to gill rakers as they have been used extensively in *Coregonus* taxonomy.

If a whitefish population is transplanted to some new lake the morphology may be drastically changed, but the gill rakers are stable. If individual fish with extreme numbers of gill plates are selected and bred from, the progeny responds to the selection, indicating a polygenic inheritance of the gill raker numbers. Finally, if two sympatric or allopatric species of whitefish are artificially crossed, their hybrids are intermediate in gill rakers, again indicating polygenic inheritance.

Within the species-groups, introgression occurs very frequently and often in such abundance that the original species can no longer be identified with certainty. Introgression may be followed by replacement and the surviving population then shows some characters of the species which has disappeared.

As sibling species of whitefish and ciscoes have lived sympatrically in thousands of European lakes since the glaciers retracted, they cannot possibly be called a sub-species. Distribution data show that they have invaded the Scandinavian peninsula at different times and they certainly have an allopatric origin.

The final paper of the symposium was also by a Swede, B. Pejler, on "Taxonomical Studies on Planktonic Rotatoria". The local variation is often considerable. Sometimes a connexion exists between the local variation and the environment. At others a variation has been established which might best be explained as the result of introgressive hybridization between closely related species. The study of the variation within particular complexes of forms, which have previously been regarded as a single species, often reveals a discontinuity in size or other characters, indicating the occurrence of sibling species. By reason of certain facts it is assumed that the Rotatoria consist to a smaller degree of cosmopolitic forms than has been believed previously.

After the strenuous symposium it was a delight to be conducted along parts of Linnaeus's Herbatio gottsundensis by Prof. G. E. Du Rietz; it was described by Linnaeus in "Herbationes upsalienses", 1753. Apart from the rich flora there was the satisfaction of seeing many plants which Linnaeus had demonstrated to his students. It was surprising to see ***Fritillaria meleagris*** growing in woodland. (On the journey back to headquarters the extensive 'King's Meadow' was visited, where it occurs in enormous numbers. It is there protected, and is so much an Upsala feature that it figures on the cover of the official guide.)

Other places of botanical interest were visited, and, after lunch, Hammerby, Linnaeus's summer residence. Here there was a meeting of the Royal Society of Science of Upsala, and Prof. N. von Hofsten read a paper on "Linnaeus's Conception of Nature". Hammerby was looking at its best, and several of the plants introduced by Linnaeus were in full bloom.

The foreign members of the Symposium later all signed a memorandum recommending that Herbatio gottsundensis be set apart as a nature reserve.

Appropriately there was a dinner and reception in the evening at Smålands Nation, the student corporation of which Linnaeus was 'inspector'. An apple tree from his birthplace was planted in its 'native' soil, and the significance of this in Swedish lore explained by the inspector, Prof. C. Nylén, who later gave a short address on the Smålands Nation; Dr. A. Uggla spoke on Linnaeus as a Smålander and Mr. J. Beskow, the curator, on student life in Upsala.

The end-of-term ceremonies with the 'promotions' of doctors were held on May 31. For the most part they followed tradition, beginning at 7 a.m. with a salute by cannon, one for each doctor, to be followed at 8 a.m. by bell-ringing from the cathedral. At 12 a.m. a procession was formed, and passed into the aula of the University, everyone in white tie and evening dress and the honorary doctors in academic robes: the order of procession gives nineteen entries, individuals and groups. The proceedings began with a discourse by Prof. S. Horstadius, promoter of the Matematisk-naturvetenskapliga fakulteten, on "Linné, djuren och människan". To accompanying orchestral music those to be promoted were grouped in the five faculties, each with its own promoter; first the jubilee doctors (of fifty years standing), then the honorary doctors, finally those who had achieved success by thesis. The name is called, the three steps of the cathedra superior ascended, a laurel crown (or a top-hat) placed on the head (accompanied by a cannon-shot without), a gold ring put on the finger, a diploma presented, a shake of the hand, a descent from the cathedra and a pause and a bow to H.M. the King of Sweden, who sat just below the platform. The three-hour ceremony was impressive and picturesque with its savour of the medieval and its national significance: it ended with the students acclaiming the jubilee and honorary doctors assembled on the steps of the University in song and speech.

The programme of the ceremony was adorned with a representation of a laurel wreath surrounding ***Linnaea borealis*** and the words "Tantus amor florum". It includes the "Promotions-formular" employed by Linnaeus for the medical faculty on October 31, 1754.

Among the recipients of honorary degrees (Fil.Dr.) were H. H. Allan (New Zealand), Julian Huxley and J. Ramsbottom: A. H. Uggla, the well-known authority on Linnaeus, was promoted doctor of medicine.

Attention should be directed to the "Inbjudningar till Doktors-Promotionerna", as it has an appendix of four important papers: F. Berg, "Linnés Systema morborum" (132 pp.); A. Liljencrantz, "Kungl. Vetenskaps-Societetens protokoll 1732–1784" (97 pp.); G. E. Du Rietz, "Linné som myrforskare" (80 pp.) and Å. Holm, "Specimina Linnaeana i Uppsala bevarade zoologiska samlingar från Linnés tid" (68 pp.).

The menu card at the graduation dinner held in the Castle was a reproduction of the frontispiece to the rare "Linnéska Institutets Skrifter"—a few hand-coloured copies of this were found recently in the archives of the Royal Society of Sciences, Upsala.

The celebrations ended on June 2 with a commemoration meeting of the Swedish Linnean Society at Hammerby. The annual pilgrimage this year marked also the fortieth anniversary of the Society. The President repeated his discourse of Thursday, though this time in Swedish: he was followed by A. G. Boerman, a Dutch medical man, who attempted an analysis of Linnaeus's character by reference to his youthful notes and writings. In glorious weather about two hundred had an alfresco lunch, at the end of which the veteran student of Linnaeus, Prof. Robert Fries, spoke of the beginning of the Society of which he was co-founder, of its objects and of the Linnean tradition. The meeting ended at Linnaeus's old house and garden at Upsala—the headquarters of the Society.

It was a memorable week, and all who took part in the celebrations will long remember the courteous and lavish hospitality of our Swedish hosts, the understanding tributes to Linnaeus, the international friendliness of the symposium—and Upsala in spring.

NATURAL RUBBER INDUSTRY

RESEARCH AND DEVELOPMENT

THE natural rubber industry is made up of units varying enormously in size, ranging from very large estates with their own modern and well-equipped factories to smallholdings, some processing their rubber in primitive fashion, others making use of co-operative equipment. The organization of research and development schemes to assist these diverse elements began naturally enough with the creation, in Ceylon and Malaya, of institutes concerned in the main with agronomic problems and with the provision of advice to growers. The success of these institutes is reflected in the substantial increases in yield—per tree or per acre—which are now being obtained, and in a steady advance in the general quality of the rubber produced.

The first appearance of synthetic rubber was probably a major stimulus in bringing some of the industry's leaders to feel that a more substantial and broadly-based effort in research and development was called for if natural rubber was to advance, or even hold its own, in a more challenging situation. The catastrophically low prices of the early 1930's showed that the industry was exceedingly vulnerable.

The British Rubber Producers' Research Association and the Natural Rubber Development Board (as it is now called) were formed some twenty years ago, and have been financed mainly by money raised by the Malayan rubber industry. Throughout their existence they have co-operated with the Eastern institutes and with sister organizations set up about the same time by the Dutch and French rubber growers. They have, however, retained their essential independence, under the control of their several boards.

In recent years the bulk of the income of the two British bodies and of the Rubber Research Institute of Malaya has been obtained from a single fund derived from a cess on Malayan rubber exports. The Malayan Rubber Producers' Council very reasonably decided some time ago that it would be useful to review the whole organization which had grown up and to consider what changes, if any, were now desirable. The report of the committee charged with this task has now been published[*], and gives an overall impression of general approval, modified by some criticisms of detail.

The membership of the committee had a strong agricultural bias, and many will feel it unfortunate that the rubber manufacturing industry was unrepresented. This unbalanced composition has led to a corresponding unbalance in the report: whereas the programmes of the Rubber Research Institute are subjected to detailed criticism, the work of the British Rubber Producers' Research Association and of the Natural Rubber Development Board is not examined in quite the same way. At the same time, the most valuable features of the report are probably the review of the objectives of the three bodies considered together rather than separately, and the recommendations as to administrative changes which are considered desirable. Numerous detailed recommendations are made, most of them of interest primarily to those directly concerned with the several bodies involved. In general they appear very sound and reasonable, and their acceptance would seem probable. The need for higher salaries to attract the right men, especially for service in the East, is cogently argued, and puts the correct emphasis on quality.

The implementation of this report will cost the industry more money: it is recommended that the cess on rubber exports be increased by 50 per cent, to yield an annual income of approximately a million pounds sterling. It is pointed out that this will still represent a substantially lower percentage of the sales than is normal in the chemical industry, which—as the supplier of synthetic rubbers—must be considered the chief competitor. The natural rubber industry has through the years been fortunate in the quality and vision of its leaders. It can be confidently assumed that this report will receive the attention and action it deserves.

G. GEE

THE MEDICAL RESEARCH COUNCIL

REPORT FOR 1955–56

THE report of the Medical Research Council for the year 1955–56[*] follows the pattern of earlier reports in giving only summaries of the work of the Council's many separate research establishments. The fullest account of their work is contained in the scientific papers published by the Council's staff, bibliographical references to which occupy sixty-six pages of this report. The main part of the report discusses general trends in medical research, a discussion which is, as the introduction emphasizes, selective and omits many investigations in which the Council's workers take part. The introduction also reminds us that virtually every conspicuous advance in knowledge depends on a mass of unspectacular, but indispensable, work done by many individuals, or by teams of workers, who bring different kinds of knowledge and skill to bear upon complex problems and are often themselves unable to make the final contribution to which outstanding advances are due.

It is, of course, impossible to review in a short space all that this report contains. Apart from the details it gives of the personnel employed by the Council, the various committees which direct the work done, the research units and the summaries of the work that these units are doing, there are, in the report, articles on clinical investigations and on research in genetics, as well as forty-seven pages devoted to various aspects of medical research.

The clinical research dates back to 1951–52, when the annual report of the Council reviewed the effect of recent scientific and administrative developments on the organization of such work. Later, the Council was invited to discuss with the Standing Medical Advisory Committee of the Ministry of Health how clinical research could be encouraged and developed in relation to the National Health Service, and an interdepartmental committee, under the chairmanship of Lord Cohen of Birkenhead, was set up to examine the question. Its report, published as a White Paper in 1953, recommended that the Medical Research Council should appoint a Clinical Research Board, and in 1953 this was done.

The Council has always maintained that its investigations should neither supplement nor replace those carried out in universities, medical schools or hospitals, but should be complementary to work done in these centres, and this report describes, in considerable detail, how the Council is doing this. In general, the Council supports clinical research by setting up units made up of its own staff, by appointing its staff to work at centres other than the Council's own establishments, by making temporary grants to workers not on the Council's staff, by making awards for the training of research workers and by organizing co-operative clinical studies. The Council is concerned with three clinical research establishments in the tropics—at Fajara in the Gambia, at the Infantile Malnutrition Research Unit at Kampala in Uganda, and at the Tropical Metabolism Research Unit at Kingston, Jamaica; and the Council hopes to develop links between these centres and clinical research units in Britain. The estimated cost of the expanded programme of clinical research for the current year, excluding that in the tropics, is of the order of £700,000.

Provision is also to be made for research organized at the level of regional hospital boards, boards of governors and hospital management committees; in this field there is to be the greatest possible freedom from detailed supervision, so that the development of local talent can be fostered.

Research in genetics is not a new activity of the Council. More than twenty years ago it began to develop work in this field. At that time although great progress had been made in the biological study of heredity and in the application of the results of this work to agriculture, human genetics had been neglected and there was need for studies of problems of inheritance and disease in man. This need was later radically increased by developments in the use of nuclear energy. The fact that exposure to radiation could cause fundamental changes in reproductive cells had been known since H. J. Muller first observed it in 1927, but the general increase in the amount of radiation to which individuals and whole communities could be exposed gave rise to the fear that man's hereditary constitution might thereby be permanently endangered, and it was clear that workers must be trained for the study of this general problem.

The Council has therefore established, during the past ten years, a number of research units to follow various lines of investigation of this kind, and observations are being made both on man and on animals. It is expected that expenditure on this kind of work will, in 1960, rise to £100,000 a year. The Council wishes it to be widely known that its scholarships and clinical fellowships provide specialized training in certain genetical methods, and that there are now good opportunities for research careers in university departments, or as members of the Council's staff. In 1955, a committee was appointed to report on the medical aspects of nuclear radiation, including its genetic aspects, and this committee dealt also with the wider problem of the hazards to the community as a whole, or to particular sections of it, which might arise from the use of nuclear and allied radiations. Its report, which was presented to Parliament in 1956 as a White Paper, has now been made available to the United Nations and will be translated into Japanese, German, French and Italian.

The section of the report entitled "Some Aspects of Medical Research" includes, this year, an article on recent advances in the study of the factors that may cause cancer of the lung, an article which reviews the evidence for and against the thesis that tobacco smoke is the only cause. The Council is supporting an expanding programme of research into lung cancer which will study the various possible factors involved, particularly tobacco smoke, and will also test the carcinogenic properties, if any, of substances obtained from the chemical analysis of tobacco and from its combustion.

Other subjects discussed in this part of the report are poliomyelitis vaccination, the prevention of whooping cough by vaccination, filariasis, protein deficiency in man, growth and renal function, microbial genetics, abnormal hæmoglobins and their relation to disease, problems of radiation, the chemistry of proteins and of antibiotics, and the use of the mass spectrometer for gas analysis in respiratory research and clinical practice.

The administration and finance of the Council's multifarious activities are dealt with in other sections of the report which, together with the details of the personnel and many research units and the summaries of their work, afford a clear picture of a great body of scientific work directed to the preservation of health and to the prevention of disease. One is impressed by the vigour of the work in hand, its forward outlook, its breadth and the depth of detail to which it penetrates. It is to this detail and to the Council's flexible control, and most of all to the devoted work of the Council's numerous staff that the results obtained are due. Much of the credit should go to those many members of staff of the Council who cannot, as the report itself points out, make the final contributions, based on their work, which the public, from time to time, acclaims.

G. Lapage

RESEARCHES IN MARINE BIOLOGY

THE recent issue of the *Journal of the Marine Biological Association of the United Kingdom* (36, No. 2; 1957) contains eighteen papers, of which ten are on work done at Plymouth; three come from Millport, two from Aberdeen, and one each from Oregon State College, Belfast and Burnham-on-Crouch. In addition there are abstracts of fifteen other papers on work done at Plymouth but published in other journals.

The eighteen papers can be roughly divided into five groups: (*a*) botany (1 paper); (*b*) natural history and descriptive zoology (7); (*c*) fish (2); (*d*) physiology and biochemistry (4); (*e*) plankton production and hydrology (4).

(*a*) *Botany*. The single botanical paper is an exhaustive taxonomic study by H. T. Powell of a very variable northern species of *Fucus*, *F. distichus*, the nomenclature of which had reached a state bordering on utter confusion. The main specific characters are the hermaphroditic conceptacles and certain closed cavities in the frond called 'cæcostomata'. There appear to be four principal subspecies, of which one reaches Shetland and one Scotland and Ireland; the species is not known to occur in English waters. From its title, this paper would appear to be the first of a welcome series.

(*b*) *Natural history and descriptive zoology*. There are two papers on copepods associated with other animals.

R. U. Gooding adds a number of new Plymouth records of copepods associated with spatangids, lamellibranchs and fish. Three new species are described, of which one is the type of a new genus.

R. V. Gotto describes the biology of the commensal copepod *Ascidicola rosea* in the very transparent ascidian *Corella parallelogramma* in Strangford Lough, Northern Ireland. The copepod normally lives in the œsophagus of its host, feeding off the mucous food-string as the latter passes by on its way to the ascidian's stomach. The copepod can climb up and down the food-string by means of specialized spiny pads and setæ. Eggs are shed in the ascidian's stomach, pass down the alimentary canal and, conveniently, hatch only on reaching the anus. There is a free-swimming life of about six days, and the host is entered by the second copepodite.

J. Llewellyn describes the larvæ of eleven species of monogenetic trematodes from Plymouth fishes. It is difficult to fit the larvæ so far known (35) into the scheme of classification now in use for the adults, and Llewellyn suggests modifications of the adult scheme in order to reconcile it with what is shown by the larvæ.

F. S. Russell describes yet another new species of deep-water scyphomedusan (*Atolla vanhoffeni*) brought in by the appropriately named R.V. *Sarsia*.

R. Phillips Dales, investigating the feeding of serpulid and sabellid fan-worms, finds that smaller worms filter relatively faster than larger worms, but that a fan-worm filters more slowly than a lamellibranch or an ascidian of the same weight. Fan-worms seem to depend mainly on inert particles for their subsistence; small flagellates, etc., can escape through the ciliated crown. The polychæte sorting mechanism is relatively crude.

A. J. Southward, continuing his studies on barnacles, investigates the effects of temperature and age on five more species. There is a rough correlation between the range of temperature over which the cirri are active and the geographical range of the species, but this correlation is by no means precise, the world-wide *Lepas anatifera*, for example, is active over a surprisingly narrow temperature-range at Plymouth.

J. E. Morton, A. D. Boney and E. D. S. Corner describe the adaptation of the small, abundant, high-level shore lamellibranch *Lasaea rubra*. Those living higher on the shore are better able to resist desiccation, start feeding sooner after wetting, filter more water in a given time, respire faster and are more tolerant of changes in salinity, than those living farther down the shore.

(*c*) *Fish*. There are two papers by T. B. Bagenal, the first being on the long rough dab (*Hippoglossoides platessoides*) in waters near Millport. The condition of the fish (based on the weight–length ratio) is at a maximum in mid-winter, and at a minimum during the spawning season in March and April, after which it recovers again. In the second paper there is a discussion at some length on the statistics of fecundity in the long rough dab and also in the plaice.

(*d*) *Physiology and biochemistry*. Dorothy Collyer, in an attempt to find causes of the variations in mortality-rate that occur between different batches of oyster larvæ, finds that there is no correlation between size or viability of larvæ and their glycogen content.

There are two more papers by J. A. C. Nicol on luminescence in polynoid worms. Separate elytra, electrically stimulated, can respond by quick flashes (which may be single or multiple) or by a luminescent glow. There is evidence for functional polarity in the nerve cord; to quote Nicol, "luminescent excitation is conducted with greater facility posteriorly over a large part of its length".

D. B. Carlisle, continuing his work on the hormonal inhibition of moulting in decapod Crustacea, examines the 'terminal anecdysis' in crabs. Some species of crabs reach a finite size after which they do not moult again. *Carcinus* moults several times after puberty, but eventually the *X*-organ produces so much moult-inhibiting hormone that further moulting is impossible unless the *X*-organ is removed. In *Maia*, on the other hand, the last moult is at puberty; by that time the *Y*-organ (which produces a moult-promoting hormone) has degenerated, and no more moults are possible even after removal of the *X*-organ. In an interesting appendix Carlisle suggests that the heaps of *Maia* which can sometimes be seen in autumn are a device not only for bringing males and females together for breeding (they can breed only once in a lifetime) but also for protecting the soft, newly moulted females by an outer layer of hard males.

(*e*) *Plankton production and hydrology*. There are two papers by John H. Steele on water samples from the Fladen grounds in the North Sea. In one, on oxygen sampling, a conversion factor for the ratio oxygen–phosphorus is calculated, and problems concerning production and surface exchange are discussed. In the other paper, carbon-14 and phosphate data are compared as means for estimating plant production. The two methods give results which vary in detail but are in general agreement. The carbon-14 method is better for measuring plant production at a particular time, but the phosphate method is better over a period.

Wayne V. Burt reappraises the data of Jones and Wills (1956) on the attenuation of light in the sea, and suggests how they can be used for estimating particle-size.

F. A. J. Armstrong continues his annual surveys of phosphorus and silicon off Plymouth. In general, the hydrographic conditions at International Station *E*1 showed the usual changes. Phosphate, however, was higher in February than at any time since 1929; in spite of a cruise in the western approaches by L. H. N. Cooper, the source of this phosphate-rich water was not discovered. In July and August there was an influx, especially into the deeper layers, of relatively cool water of lower salinity.

John S. Colman

A WILSON CLOUD CHAMBER WITH TIME-MARKING OF PARTICLE TRACKS

By Dr. D. GABOR, F.R.S., and B. HAMPTON

Department of Electrical Engineering, Imperial College of Science and Technology, London

In Wilson cloud chambers using magnetic fields, the momentum of the particles can be determined directly by measuring the curvature of the tracks, but the velocity (energy, mass) only indirectly, from the observation of recoil electrons, ionization density and other observations. It would therefore be desirable to possess an instrument which puts time marks on the tracks, at equal intervals of the order of 10^{-10} sec., to allow a direct measurement of velocities. One of us (D. G.) has proposed achieving this by turning the Wilson cloud chamber into a resonating microwave cavity, which operates with an almost uniform high-frequency field so near to breakdown that considerable multiplication of secondary electrons takes place near every peak, producing a periodic thickening of the tracks. This would also make possible the observation of emission delays of the order 10^{-11} to 10^{-10} sec. in nuclear events.

A high-frequency field near the breakdown limit supplies to electrons energies such that an appreciable fraction will create at least one further pair during their life-time. But if the life-time is long, as in inert gases, the instant of creation of the first electron is of no importance. On the other hand, in gases with strong electron attachment, such as chlorine or 'Freon', the life of a free electron at atmospheric pressure will be of the order of 10^{-10} sec., comparable with a half-cycle of a field of, say, 3,000 Mc./sec., which is $1 \cdot 67 \times 10^{-10}$ sec. Few electrons will then survive into the next cycle, and one can expect considerable excess ionization in the case of secondary electrons created just before the field goes through a peak. This will produce a modulated track, thickened at intervals of $\frac{1}{2}\ \beta\lambda$, without any significant distortion of the track, so that it would not prevent simultaneous measurement of the momentum.

It is almost immediately evident that the successful realization of such a scheme is mainly a question of adequate power. The breakdown field of air at atmospheric pressure at microwave frequencies is about 28 kV./cm., which corresponds to a peak energy of 4×10^{-4} joule/cm.³. This must be renewed ω/Q times per second. With a frequency of 3,000 mc./sec., ($\lambda = 10$ cm.) and $Q = 1{,}000$, this works out as 750 watts/cm.³ of useful volume. In 'Freon', with a breakdown strength of about 90 kV./cm., it would be about 10 kW./cm.³.

These would not be considered as unusually high powers if one could confine the pulse to a few microseconds, because large pulsed magnetrons are in existence which can deliver 2–4 megawatts for such short durations, and klystrons even ten times as much. The scheme would therefore not offer great difficulties if the cavity cloud chamber could operate near an accelerator so powerful that it produces several tracks of interest per microsecond (using an electron-optical shutter to keep off the beam for the rest of the sensitive period of the cloud chamber). But in the experimental investigation to be described, which we started in 1954 to pave the way for more ambitious schemes, we had to confine ourselves to rather weak radioactive sources. These supply a few α-tracks in about 10 msec., which is of the order of the sensitive period of ordinary cloud chambers. We were fortunate in obtaining for this work, by courtesy of the Research Laboratories, General Electric Co., Ltd., the experimental magnetron *VX 3043*, one of the largest d.c. magnetrons in existence; but even with this we could not obtain more than 2·2 kW. output at 3,000 Mc./sec., in pulses of 15 msec. duration. Though by careful design of the microwave circuit we were able to direct 90 per cent of this into the cloud chamber cavity, the 'loaded Q' could not be made larger than about 500. This would be just sufficient for 0·1 cm.³ of 'Freon', if it were possible to make the field uniform in the whole volume. We had therefore to confine our experiments to the diatomic gas with the lowest breakdown strength, which is hydrogen (15 kV./cm.). This left us only with a marginal chance of success, because the electron attachment of hydrogen is negligible. It has, however, an appreciable slowing-down effect on electrons below its ionization energy (about eighty times larger than the elastic fractional loss $2m/M$). Though a secondary or tertiary electron survives over a very great number of cycles, its probability of rising above the ionization-level decreases rapidly after the first half-cycle in which it was created. This enabled us to obtain some measure of success with the apparatus now to be described.

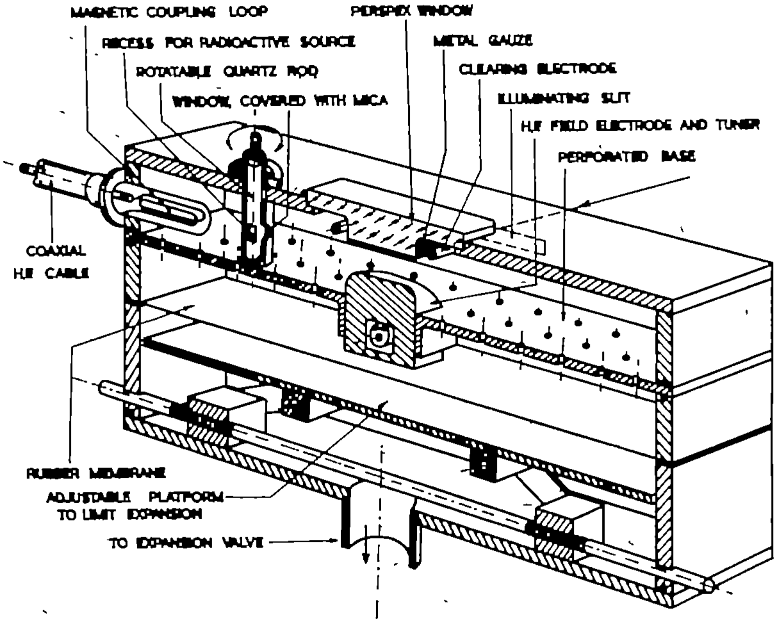

Fig. 1. Cavity cloud chamber

The cavity cloud chamber used in the final experiments is shown in Fig. 1. The cavity is rectangular, with a re-entrant plunger which concentrates the field in a rather small fraction of the total volume. This is faced by a 'Perspex' window, for observation, also re-entrant, which is covered with a copper or silver gauze, fine enough not to obstruct the photography if one uses an optical system of small focal depth. The bottom of the cavity is a perforated metal plate, and the expanding part of the chamber is below it. This makes it possible to keep the walls of the cavity free from condensed water or alcohol, which would appreciably spoil its resonant properties. These were, of necessity, rather poor, because one cannot concentrate the field of a cavity operating with a wave-length λ into a volume with a base less than about $\lambda^2/4$ without reducing the Q well below its optimum value, and this was further reduced by the illuminating slit and by the gauze-covered observation window. This was the reason why the Q of the cavity by itself was only about 1,000, and the loaded Q 500, whereas without the plunger and the re-entrant window one can obtain about four times as much. In other words, once power is scarce, one cannot get the full benefit of restricting the volume.

The expansion was effected by a thin rubber sheet (latex), which closes the bottom of the space below the perforated plate. When the vacuum valve is opened this settles snugly against the walls and against a movable platform which permit adjustment of the expansion ratio between rather wide limits. A water–alcohol mixture (35 : 65) gave the best results in hydrogen, with an expansion ratio of 1·38. All metal parts of the chamber were rhodium-plated.

The source was a 0·1 mc. sample of thorium-228, which was contained in a small recess of a quartz rod, covered with a thin mica flake. This was arranged so that it could be rotated in a polystyrene tube, with a window, also covered with a mica sheet. Normally the recess faces away from the window. It could be jerked by a push-magnet *via* a Bowden cable so that it faced the window for about 15 msec., and was then returned by a powerful spring.

Much care had to be devoted both to the high-frequency and to the pulse circuits to ensure correct operation. It is not possible to switch on a magnetron which is critically coupled to a high-Q cavity without changes of mode and internal breakdown. Hence a magic tee was provided between the magnetron and the cavity, with the two side-arms carrying matched water loads. During the rise of the pulse, the magnetron power was directed into these loads. After an interval of the order of a microsecond, two low-pressure mercury discharge tubes (arranged in the side-arms at distances from the magic tee differing by $\lambda/4$) came into operation, which blocked the flow to the water loads and directed 80–90 per cent of the magnetron power into the cavity, through a matching transformer, a coaxial cable, and the coupling loop shown in Fig. 1. The fields in this loop were very strong, and it had to be cast into paraffin or polystyrene to prevent sparking.

In order to obtain powers of the order of 2 kW. from the magnetron *VX* 3043, the thoria cathode had to be kept hotter than could be achieved by the heating coil alone. It was therefore kept in continuous operation with 200 watts output and pulsed 4 times per sec. with the full pulse power, which was 4·25 kW. (5·3 kV., 0·8 amp.). With somewhat less than 50 per cent efficiency, this gave a total power of 2·2 kW for 15 msec. The pulse power was obtained from a large 6-phase rectifier, with a peak-to-peak ripple of 5·7 per cent. As the ripple frequency was 300 c./sec., there were 4¼ ripple-cycles per pulse.

It was evident from the start that in order to achieve success it was necessary to have very flat-topped pulses of accurately adjustable height, and very small ripple, so that the high-frequency field could be kept just below breakdown. We achieved this by using a large choke of 50 H. which was permanently excited with a d.c. current of the same strength, about 0·8 amp., which the magnetron required during the pulse. This choke was short-circuited when the magnetron was not in operation, and was placed in series with the magnetron immediately after the start of the pulse by opening the short circuit. The choke instantaneously impresses its own pre-set current on the magnetron, and at the same time reduces the ripple to ¼ per cent peak-to-peak. The current then changes exponentially from the pre-set, initial value to its ultimate value, determined by the rectifier and proportional to the mains voltage, with a time constant of 5 msec. Maximum constancy is achieved if the initial and the ultimate values are the same; there is then only a ¼ per cent ripple in the otherwise flat top. Before every experiment, a number of trial runs were made, adjusting the pre-set choke current to be equal to the pulse current, by observing the flat top on a cathode-ray oscillograph. Both were then raised together, until breakdown in the cavity occurred in about 50 per cent of the trials.

A rotating switch system, including a high-voltage switch, operated the magnetron 4 times per sec., with its output going into the water load. When a photograph was to be taken, a second shaft with adjustable cams was coupled to the switch system, so that the following operations were carried out in sequence: release of the expansion valve (which had a delay of about 75 msec.), rotating the radioactive source, switching on the high-voltage pulse, which at the same time was applied to the discharge tubes (which blocked off the water loads automatically, with just about the right delay of the order of a microsecond), opening the short-circuit of the choke, and triggering the camera shutter which in turn triggers the flash-tube system used for illumination.

About four hundred photographs have been taken in hydrogen, of which about half led to breakdown. Of the remaining 190, two photographs showed clearly one modulated α-track each. These are reproduced in Fig. 2. Both have nodes spaced by 2·7 mm., which corresponds to $\beta = 2{\cdot}7/50 = 0{\cdot}054$, in good agreement with the velocity of α-particles of this source, at this part of their range. It may be noted that all the other α-tracks—there were nearly a thousand—which were sharp enough to show up modulation if it had existed were smooth and even, so that these two tracks with three evenly spaced nodes each cannot be explained by accidental grouping of nodes. Nor was any modulation observed in several hundred photographs taken without high-frequency fields.

In view of the precautions we have taken to ensure a field close to breakdown, these results might suggest an extremely narrow useful field-range in hydrogen; but closer analysis shows that the observed yield of about one modulated track in five hundred is quite compatible with a useful range of several per cent. The main reason for this is in the characteristic of magnetrons. In the high-output region in which we have operated, 1 per cent variation of the magnetron current produces 13 per cent variation in the output power, and 6 per cent in the field intensity. Hence the ¼ per cent ripple in the current produced a 3 per cent ripple in the field. Moreover, if the pulse current supplied by the rectifier, which is propor-

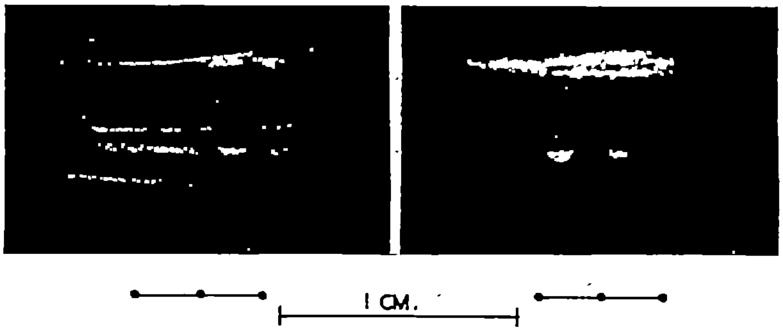

Fig. 2. α-Tracks of thorium-228 in hydrogen, modulated with 3,000 Mc./sec.

tional to the mains voltage, departs by only 1 per cent from the current pre-set in the choke, the voltage will rise or fall by 3 per cent during the pulse. We have calculated that if the pre-set value of the current departs only by ±½ per cent from the optimum value, and the mains voltage fluctuates also by ±½ per cent around the optimum, the useful time in all photographs, assumed as the time in which the field remains within 1 per cent of the breakdown strength, is only 3 per cent in those trials which do not lead to breakdown. It is likely that our accuracy of adjustment was nearer ±1 per cent than ±½ per cent, which makes this fraction only 0·5 per cent. It is also very likely that the useful part of the chamber volume, that is to say the fraction in which the field intensity differed by less than 1 per cent from the maximum, was not more than 1/10. (Note that both modulated tracks are nearly in the same position.) This would lead to an expectation value of about 1 : 2,000; hence the observed yield of 1 : 500 is quite compatible with a field-range of 2–4 per cent below breakdown suitable for producing clearly modulated tracks of α-particles. This confirms us in our opinion that the two photographs shown in Fig. 2 are not freaks.

We believe, therefore, that these experiments, though not very successful in themselves, augur rather well for the application of the method on a serious scale. With a power of 20–40 kW. instead of the 2 kW. which was available in our experiments, it would be possible to use chlorine–argon or 'Freon'–argon mixtures, with a breakdown strength of 40–60 kV./cm., in volumes of reasonable size. By using large klystrons instead of magnetrons, most of our difficulties in accurately adjusting the field-intensities would vanish. Moreover, our experiments relate to α-tracks, which are rather unsuitable because of their very high degree of ionization. Conditions for modulation would be far better in the case of meson tracks, which are also of much greater interest.

This project was financed by the Royal Society Paul Instrument Fund, and we are glad to express our indebtedness to the Paul Instrument Fund Committee. We also wish to thank the Research Laboratories of the General Electric Co., Ltd., Wembley, for the loan of the special magnetron, and Messrs. Willshaw, Stainsby and Cooper for instructing us in the use of this device. Our thanks are due also to Prof. J. G. Wilson for much encouragement and advice in cloud-chamber techniques.

EFFECTS OF OXYGEN UPON LIGHT ABSORPTION BY GREEN ALGAE

By Prof. BRITTON CHANCE

Johnson Foundation, University of Pennsylvania, Philadelphia, Pennsylvania

AND

BERNARD STREHLER

Department of Biochemistry, Fels Fund, University of Chicago, Chicago, Illinois

IN spectroscopic studies of the purple bacteria, a correlation between the effects of oxygen and light provides direct information on the nature of the light reaction and assists in identifying the point in the respiratory chain at which photo-produced oxidants may react[1,2]. Many papers have appeared recently describing spectroscopic changes caused by illumination of *Chlorella* and other green cells[3-6], but no dark process has yet been described which produces the same effects as illumination. It has been found that oxygenation of various types of anaerobic green cells causes the appearance of the absorption band at 515 mμ that has already been observed to appear upon illumination with red light. In the region 475–560 mμ the spectroscopic effects of oxygenation and illumination are very similar and these results lead us to suggest that the compound absorbing at 515 mμ results from an oxidation or an analogous excitation of a 'dark' compound absorbing at 475 mμ. The results also afford an explanation of the divergent conclusions of Witt[7].

The double-beam spectrophotometric method is similar to that previously used in studies of purple bacteria[1] and in the photodissociation of the cytochrome a_3 carbon monoxide compounds[10]. In the case of acetate-grown *Chlamydomonas*[8], the respiration was sufficiently rapid for the oxidized-minus-reduced difference spectra to be measured in a cuvette in the manner used for the study of cytochromes. Slowly respiring algae were placed in a moist chamber, the horizontal base of which was very close to the photomultiplier tube. The algae settle on the base of this chamber and form a uniform layer suitable for spectrophotometric observation. The algae were equilibrated with oxygen–carbon dioxide or nitrogen–carbon dioxide mixtures. For red illumination, a Corning 2030 filter was interposed between the algae and the white light and a blue filter (Wratten 44*A*) between the algae and the photocell. Oxygen concentrations were monitored with a platinum electrode.

By alternately oxygenating and de-oxygenating the algal suspension, absorbancy changes are measured with respect to a reference wave-length (usually 495 mμ) and are plotted as illustrated in Fig. 1 for *Chlorella* (supplied by Dr. Ruth Sager) and *Chlamydomonas* (supplied by Mr. L. M. Pakman). Absorbancy increases occurring on oxygenation are plotted as an upward deflexion. The *Chlorella* suspension shows a peak at 516 mμ and the *Chlamydomonas* suspension, in which the range 490–648 mμ is covered, show a similar peak at 515 mμ, a shoulder at 530 mμ and a trough at 550 mμ, with no other large changes out to 648 mμ.

It is possible to identify which phase of the various reactions that follow illumination of the anaerobic algae corresponds to the oxidized-minus-reduced spectrum. In Fig. 2, we have recorded the reactions

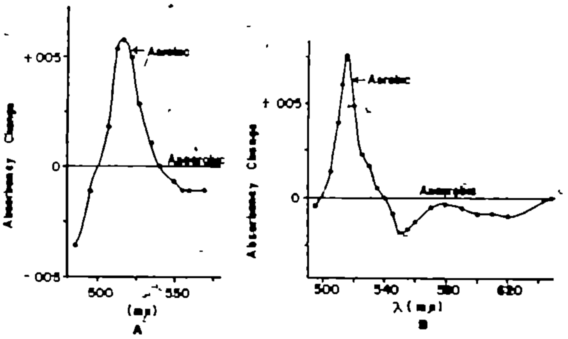

Fig. 1. Anaerobic minus aerobic difference spectrum for *Chlorella* (*A*) and for *Chlamydomonas* (*B*). The absorbancy changes were measured with respect to 495 mμ as described in the text. Absorbancy increases occur on oxygenation of the anaerobic algae

following red illumination. The *Chlorella*, initially anaerobic, are illuminated for about two minutes. During this interval there is an abrupt increase of absorbancy at 502 mμ and at 522 mμ, measured with respect to 495 mμ. This abrupt increase is followed by a small, slow decrease of absorbancy (phase 1) which in separate experiments is found to be caused by a decrease in the light-sensitivity with time. On cessation of illumination, a small but abrupt decrease of absorbancy occurs, the transition from illuminated to dark aerobic cells (phase 2). During the next ten minutes a slow change of absorbancy occurs (phase 3). This is caused by dis-oxygenation of the cells by dark respiration. A repetition of these experiments at a variety of wave-lengths gives a difference spectrum for the phase 3 transition which agrees with that of Fig. 1 to within the experimental error. This decrease of absorbancy recorded in phase 3 is the major part of the absorbancy change caused by illumination, and can be caused by either added oxygen or by photo-produced oxygen or other oxidants. Since the specificity of molecular oxygen in biological oxidations is well recognized, it is proposed that the appearance of the absorbancy band at 515 mμ in the phase 3 transition is an oxidation and its disappearance represents a reduction.

In the spectra published by other workers in this field on the effect of illumination, none has specified whether the results were obtained under aerobic or anaerobic conditions, although Duysens has noted that the effect at 515 mμ was enhanced by anaerobiosis[8]. However, we can identify the state of aerobiosis of the various preceding papers from the kinetics of the reactions following cessation of illumination. If the effects are rapid, as in the case of Witt[7] and Kok[9], the phase 2 transition was probably measured (reaction D[11]). If the effects are slow, as they must have been in the case of Lundegårdh who used roughly half a minute to scan the spectrum[5], the effects may be attributed to the phase 3 transition. Strehler and Lynch[6], who describe a 'negative overshoot' phenomenon, showed the phase 1 effect in their kinetic records and may have measured a spectrum corresponding to phase 2.

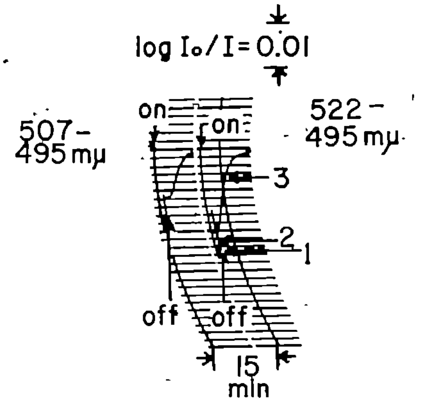

Fig. 2. Sample records showing at two wave-lengths the kinetics of the absorbancy changes that occur upon illumination of anaerobic *Chlorella* and upon cessation of illumination, after a light-interval of about two minutes

Witt has concluded that the increased absorbancy at 515 mμ that he observed, here identified as the phase 2 transition, represents a reduction[7], while the considerations given above lead us to the conclusion that the phase 3 increase of absorbancy corresponds to an oxidation. Since the phase 3 and phase 2 transitions are found to have similar difference spectra, the inconsistency of the two conclusions is obvious. Witt, however, was unable to cause the phase 2 transition to occur by the addition of reductant and based his conclusions only upon the observation that the phase 2 effect in spinach chloroplasts disappeared more rapidly in the presence of one Hill oxidant (2-6-dichlorophenolindophenol, although no appreciable effect was caused by others (ferricyanide, quinone[11]). Since we have shown the phase 3 effect to be caused by one of the most specific biological oxidants, molecular oxygen, we prefer the explanation that both the phase 2 and phase 3 transitions represent oxidations upon illumination and reductions upon cessation of illumination. It is further proposed that the phase 2 transition represents an increase in the steady-state oxidation-level beyond that obtainable by oxygen; but in this case the oxidation is opposed by a highly reactive photo-produced reductant which is responsible for the rapid disappearance of the phase 2 effect upon cessation of illumination. In cases where a temporary excess of reductant over oxidant occurs, negative overshoot phenomena such as those described by Strehler and Lynch[6] can be accounted for.

In summary, the pigment appearing at 515 mμ upon illumination of green cells is concluded to be an oxidation-reduction indicator responsive to intracellular generation of oxidants and reductants produced in photosynthesis. Its identification with the primary process of photosynthesis[11] cannot be accepted until the nature of the pigment has been elucidated and its apparent absence in *Porphyridium*[4] and in a photosynthetic mutant of *Chlamydomonas*[12] can be accounted for.

This investigation was supported in part by the National Science Foundation.

Longitudinal Polarization of the Positrons from the Decay of Unpolarized Positive Muons

It is now well known that parity is not conserved in weak Fermi interactions, and that this generally results in longitudinal polarization of the spins of the emitted particles. Very strong polarizations of the muons emitted in pion decay[1], and of the electrons emitted in beta decay[2], have already been detected. The experiment reported here was aimed at detecting longitudinal polarization of the positrons emitted in the decay of unpolarized muons.

The strength of the various effects leading to non-conservation of parity observed so far has led to the hypothesis of a specially simple theoretical scheme, the two-component neutrino theory with lepton conservation[3]. If the beta-decay interaction is taken as being a scalar and tensor mixture, this scheme leads to the prediction that the positrons from positive muon decay should be predominantly 'left-handed', that is, that the spins of the positrons should point in the opposite direction to their direction of motion. A determination of the positron polarization thus offers a direct test of the theory.

We have determined the sign of the polarization experimentally by a method first applied by Goldhaber, Grodzins and Sunyar[4] to the decay electrons from strontium-90, and by Lederman[5], though with as yet inconclusive results, to the muon decay electrons.

The positive pion beam of the Liverpool synchro-cyclotron was brought to rest in a 2-in. thick carbon target which then became a source of positrons produced in the π–μ–e decay sequence. Some of these positrons passed through two scintillation counters into a lead plate in which they produced bremsstrahlung quanta. These quanta have been shown by McVoy and Dyson[6] to retain a large fraction of the polarization of the incident electrons.

The quanta passed through a cylinder of iron 6 in. long which could be magnetized axially in a direction parallel or anti-parallel to the direction of motion of the quanta. They were then detected by a 4½-in. diameter crystal of sodium iodide. The total cross-section for Compton scattering is smaller, in our energy-range, when the spins of quanta and scattering electron are parallel than when they are anti-parallel, and the experiment compared the transmission of the quanta through the iron in the alternative states of magnetization.

The required pulses from the sodium iodide detector were selected by forming a fast triple coincidence with the two positron counters and using this to gate the pulses linearly to a pulse-height analyser. A counter telescope in the pion beam served as monitor, the direction of magnetization being reversed after a certain number of monitor counts, chosen to give intervals of about 1 hr. between reversals.

Great care was taken to screen the photo-electron multipliers from the stray magnetic field, and extensive checks were made to confirm that reversal of the field did not affect the sensitivity of any of the counters. An overall check was made using the unpolarized fast electron contamination of the negative pion beam instead of the muon decay positrons. Finally, to show that the arrangement behaved as expected with polarized electrons, the experiment of Goldhaber *et al.* with strontium-90 was repeated and the same result obtained.

Two runs of five days duration were made with the muon decay positrons and the combined results are displayed in Fig. 1. Here we have plotted the difference between the pulse spectra from the sodium iodide detector for the two directions of magnetization as a percentage of the mean. The errors shown are the statistical standard deviations. A rough estimate has been made of the expected form of this plot on the basis of formulæ given by McVoy and Dyson[6] and by Gunst and Page[7], and this is indicated by the broken line. The maximum of the curve should be in the region of 5 per cent if the positrons are fully polarized.

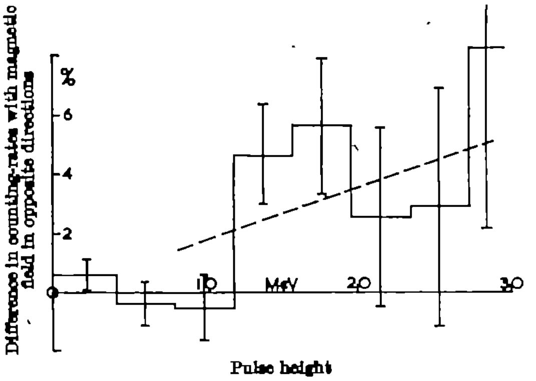

Fig. 1

The results point to a high degree of longitudinal polarization of the muon decay positrons. The transmission of the iron core was greater when the north pole was towards the positron source, showing that the positrons were predominantly 'right-handed', having their spins pointing in the direction of motion. The statistical significance of the result can be demonstrated by combining all the measurements on pulses greater than 12 MeV., when we have a difference of 4·54 ± 1·18 per cent. The probability that the difference is really zero is then 1 in 17,000.

Thus the result of the experiment is contrary to the prediction of the two-component theory with lepton conservation. However, it appears that the scheme can be saved if the beta-decay interaction has been wrongly identified[8] (that is, if the interaction is vector and axial vector rather than scalar and tensor, and the leptonic signs of neutrino and antineutrino are reversed). We intend to carry out the analogous experiment with electrons from the decay of unpolarized negative muons. On very general grounds[8], the polarization should be equal in magnitude to the positron polarization but opposite in sign.

We wish to record our thanks to Prof. H. W. B. Skinner for the close interest he has taken in this work, and to Prof. J. M. Cassels and Dr. H. Uberall for valuable discussions. The work with the cyclotron was greatly facilitated by the co-operation of the operating crew under Mr. B. Halliday. Two of us (G. C. and T. M.) acknowledge the receipt of grants

Nature of the Product condensed at Low Temperatures from Dissociated Peroxide Vapour

THE products condensed at low temperatures from dissociated water or hydrogen peroxide vapour, and also from the H + O_2 reaction, have been the subject of frequent investigation. When warmed near − 120° C., these products invariably transform from glassy to crystalline deposits, simultaneously evolving oxygen, and at room temperature water and hydrogen peroxide remain. The hypothesis, however, that this behaviour arises from the existence of an isomer of hydrogen peroxide[1] or an equivalent 'complex'[2,3] stable only at low temperatures has recently lost ground in favour of one based on the existence of trapped radicals[4-6] in the matrix of amorphous ice.

We have recently investigated the dissociation of pure hydrogen peroxide vapour in an a.c. discharge, and a study of the condensed product has formed an important part of the work. When the products of the reaction were condensed at − 78°, no peroxide or evolved oxygen was detected on warming, and the residue was pure water. Hydrogen peroxide and evolved oxygen (mass spectrometric analysis confirmed that no hydrogen was present), however, were always obtained from deposits condensed at − 183° or − 195°, the yields increasing as the trap temperature was changed from − 183° to − 195°, and decreasing as the distance between discharge and trap was increased (cf. ref. 3). The influence of current and rate of hydrogen peroxide input on the condensed and uncondensed products was also systematically studied. Variations designed to increase the concentration of radicals issuing from the discharge led also to increases in the amounts of hydrogen peroxide and evolved oxygen, but their ratio was little affected.

The above characteristics confirm that the condensed substance produced in our studies is entirely analogous to those obtained in the work already cited. Further information on the temperature and rate at which oxygen was evolved was therefore sought, since it is this aspect which has hitherto received least attention. In agreement with others, preliminary studies showed that, irrespective of the quantities of products, major evolution was first observed near − 120°. Using constant-temperature baths, the rate of evolution from a standardized deposit was then studied in separate experiments (Fig. 1). Extremely small, but quite definite, quantities of oxygen were produced at − 137° and − 123°. By − 115°, however, the major evolution process was already much in evidence. The results collected in Fig. 1 emphasize the suddenness of its onset. Taken together with the experiment at − 123°, the warming delay before evolution in experiments at − 115° and − 108° indicates a critical temperature for evolution very close to − 120°.

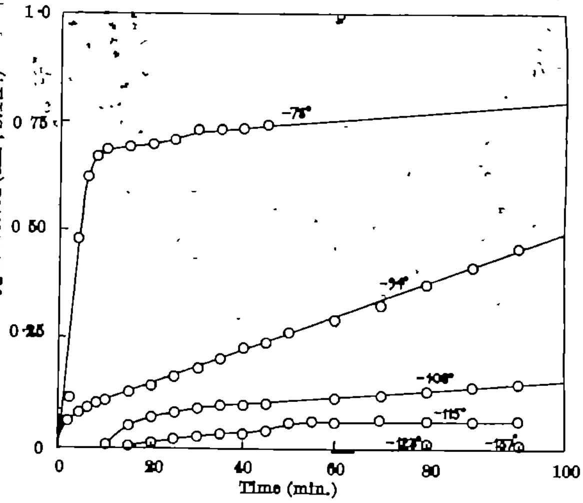

Fig. 1. Rate of evolution of oxygen from the condensed product at various temperatures. In each case the product was formed at − 195° in 1 hr. at the same current and flow-rate. The 'total evolved oxygen' from each deposit (20° C.) was 1·4 cm.³, stp. The zero of time corresponds to the instant at which the − 195° bath was replaced by the warmer bath

We suggest that for the real significance of this 'chemically derived' critical temperature one should look to recent studies of the physical structure of condensed water vapour. Ghormley[7], and more particularly Blackman and Lisgarten[8], have shown that amorphous ice undergoes a sharp transition to a cubic form at − 120°. It is felt that, of the two hypotheses mentioned, that which postulates recombination of trapped radicals is more in line with initiation by a solid transition. During the formation of the deposit, one may suppose that OH and HO_2 radicals[9,10] present in the stream issuing from the discharge become first adsorbed and then incorporated in the amorphous ice as the deposit builds up. The radicals form hydrogen bonds, so that below − 120° they are almost certainly immobile in the bulk of the deposit. At − 120°, the re-ordering of the hydrogen bonding which accompanies the crystallization renders a fraction of the radicals mobile for bimolecular reactions, for example:

$$OH + HO_2 = H_2O + O_2$$
$$OH + OH = H_2O_2$$
$$HO_2 + HO_2 = H_2O_2 + O_2$$

Oxygen probably diffuses out of the condensed product along grain boundaries. The adsorption step (*q.v.*) is considered important: the increased residence time at lower substrate temperatures is probably partly responsible for the increased yields of hydrogen peroxide and oxygen evolved found under those conditions. Moreover, selectivity at this stage may be an influence underlying the ratio of peroxide to evolved oxygen.

Anion Exchange Behaviour of Yttrium

In a recent paper[1], we have reported the uptake of thorium on a strong-base anion exchange resin from sulphate and carbonate solutions. It was also observed in this laboratory that a trace amount of yttrium-90 was adsorbed on such resin from ammonium sulphate, sulphuric acid and sodium carbonate solutions.

The resin employed was 'Dowex 1 × – 8', consisting of 100–200 mesh beads. Before use, it was converted to the sulphate or carbonate form and then stored in a desiccator over a saturated solution of sodium bromide. Columns of 8-mm. diameter filled with 3 gm. of the resin were prepared. Yttrium-90 tracer, supplied as hydrochloric acid solution, was evaporated almost to dryness on a water-bath and dissolved in solutions of ammonium sulphate, sulphuric acid and sodium carbonate of various concentrations. For the measurements of radioactivities, the samples were prepared as follows: for column studies, one drop of the effluent was evaporated on a glass disk under an infra-red lamp, while, for equilibrium studies, yttrium-90 in the solution equilibrated with resin was coprecipitated with 5 mgm. of ferric iron and the radioactivity of the dried precipitate was noted.

Only column studies were carried out for ammonium sulphate and sulphuric acid solutions. The resin columns were first treated with simple ammonium sulphate or sulphuric acid solutions of certain concentrations. Then a 0·1 ml.-portion of yttrium-90 tracer solution was placed on the top of each column. The elution was carried out with ammonium sulphate or sulphuric acid solution at a rate of 0·3 ml. per minute.

From the elution curves obtained, the distribution coefficients were evaluated by the relationship,

$$V = I + M \times K_d$$

where V is volume of effluent necessary to obtain the eluted yttrium in maximum concentration in the effluent, I is the fractional interstitial space, M is total amount of resin and K_d is the distribution coefficient (radioactivity per gm. resin/radioactivity per ml. solution). The values of K_d are shown in Table 1.

Table 1: K_d VALUES FOR SULPHURIC ACID AND AMMONIUM SULPHATE SOLUTIONS

Solution	K_d
1 M Ammonium sulphate	~ 1
0·1 M Ammonium sulphate	$\sim 3·5$
0 01 M Ammonium sulphate	~ 3
0 1 M Sulphuric acid	< 1
0·01 M Sulphuric acid	~ 1 5

Experiments were carried out at room temperature

Both column and equilibrium studies were carried out for carbonate solutions.

After the resin bed was treated with 0·1 M sodium carbonate solution, 10 ml. yttrium-90 solution was added to the top of the column. Then the column was washed with 20 ml. of 0·1 M sodium carbonate solution. No activity of yttrium-90 was detected in the effluent.

The adsorption of yttrium-90 from 1 M sodium carbonate solution was rather weak so that a K_d of 6 was obtained by the column method as described above.

A weighed portion of the resin was allowed to stand overnight in a solution of sodium carbonate under consideration. Yttrium-90 tracer solution was added to the system. After the whole system was placed in glass-stoppered Erlenmeyer flasks, it was shaken on a mechanical shaker in a thermostat at 25° C. until the exchange equilibrium was attained. The values of K_d are given in Table 2. It is remarkable that the adsorbability of yttrium-90 increases rapidly with decreasing carbonate concentration.

Table 2. K_d VALUES FOR SODIUM CARBONATE SOLUTIONS (AT 25° C)

Solution		K_d
1 M Sodium carbonate	$\sim$	6*
0·67 M Sodium carbonate	$\sim$	20
0·34 M Sodium carbonate	$\sim$	100
0·1 M Sodium carbonate	$\sim$	3,000
0 01 M Sodium carbonate	$\sim$	104

* This value was obtained by the column method at room temperature

Details will be published elsewhere.

A New Compound of Univalent Cobalt

Polarographic behaviour of the ions Co(dipy)$_3^{3+}$ and Co(dipy)$_3^{2+}$ shows that they are reversibly reduced at the dropping mercury electrode to a compound of univalent cobalt which does not decompose in neutral aqueous or ethanolic solutions.

The redox potential, measured as half-wave potential, of the Co$^{\text{I}}$—Co$^{\text{II}}$ couple in the complex with dipyridyl was found to be – 0·91 V. (vs. aqueous saturated calomel electrode) in a 1 M lithium chloride ethanolic solution and – 1·24 V. (vs. saturated calomel electrode) in aqueous solution.

As the polarographic behaviour of the Co$^{\text{I}}$—Co$^{\text{II}}$ couple suggested that the complex of univalent cobalt with dipyridyl is stable in the solution, attempts were made to carry out the reduction in the solution and to isolate the complex.

As the starting compound, Co(dipy)$_3$(ClO$_4$)$_2$.3H$_2$O (prepared according to Burstall and Nyholm[1]) was chosen. From among many reducing agents studied, sodium borohydride proved to be the most suitable. To a suspension of $Co(dipy)_3(ClO_4)_2 . 3H_2O$ in a water–ethanol mixture (1 : 3) an aqueous solution of sodium borohydride was slowly added. The reduction took place immediately, forming a deep blue solution. A portion of the solvent was then slowly distilled off *in vacuo* at ordinary temperature. Very fine dark blue crystals separated during this operation. The crystals were filtered off, washed with a small amount of water and dried *in vacuo*. All these operations had to be carried out in an inert atmosphere, because the product is highly sensitive to oxidation.

Preliminary analysis showed that the dried compound has the composition $Co(dipy)_3ClO_4$. The compound is slightly soluble in water and much more so in ethanol, giving a deep blue solution. The solutions in ethanol are relatively stable in the absence of oxygen. The solid, perfectly dry compound is stable in an atmosphere of nitrogen. The diffusion coefficient of the blue Co^{I}-complex is about 30 per cent greater than that of $Co(dipy)_3^{2+}$, showing, in accordance with analysis, that the particle is smaller.

The valency of cobalt in this compound was determined polarographically. The blue compound is anodically oxidized at the dropping mercury electrode at the same potential at which the ion $Co(dipy)_3^{2+}$ is reduced (see Fig. 1); the height as well as the shape of the wave correspond to a one-electron process, showing that the compound contains univalent cobalt. The oxidation product of the ion $Co(dipy)_3^{+}$ in the presence of excess of dipyridyl is the ion $Co(dipy)_3^{2+}$. The same product is obtained also by oxidation with oxygen. Furthermore, during the electrolytic reduction of $Co(dipy)_3^{2+}$ a deep blue colour is observed at the electrode surface, indicating that the product of the one-electron reduction of $Co(dipy)_3^{2+}$ is identical with the compound isolated.

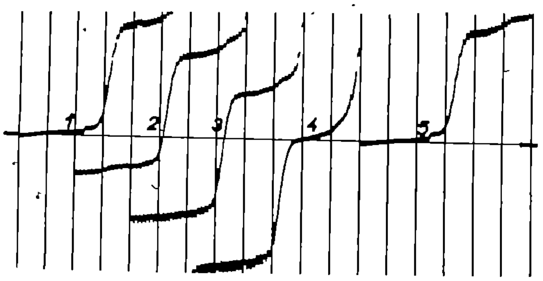

Fig. 1. Reduction of $Co(dipy)_3^{2+}$ with sodium borohydride. Curve 1: 0·07 *M*-dipyridyl in ethanol saturated with lithium chloride, 1×10^{-3} *M* Co^{II}. Curves 2–4: Stepwise reduction with aqueous solution of sodium borohydride. Curve 5: Solution 4 after oxidation with air. From −0·2 V. (saturated calomel electrode); 200 mV. (abs.); nitrogen atm.; *S* = 1 : 50

It was not possible to decide whether the univalent complex ion is diamagnetic or paramagnetic, since contamination by Co^{II} caused much uncertainty in the magnetic measurements. However, from the polarographic behaviour, it is expected that the compound has no unpaired electron.

Softening of Steels by Cold-Working

A phenomenon of softening in quenched and tempered steel subjected to small amounts of deformation has been reported by Armour[1] and by Wilson[2]. Other workers had also observed that the hardness of sorbitic and troostitic steels remained constant during the early stages of cold-working[3,4].

Based on similar softening effects observed after deformation of metals previously cold-worked in the opposite direction, Polakowski[5] formulated a general rule stating that work-softening would take place whenever the method of deformation used would produce an internal stress system different from that left after the preceding treatment, be it mechanical or thermal in nature. Later, Wilson[2] attempted to explain the mechanism of work-softening on the basis of dislocations. By determining the strains on cementite particles by means of X-ray and Curie temperature measurements, Wilson had previously shown[6,7] that the textural stresses set up between the ferrite and cementite as a result of cold-working may be quite high. Such a textural stress system, which is present in quenched and tempered steels, may be greatly modified as a result of plastic deformation by being, for example, changed from an isotropic to an oriented system. Indentation hardness tests may indicate softening or very low rates of work-hardening during this process, but the extent of the effect appears to be influenced by the scale of the internal stress pattern as well as the magnitude of the initial textural stresses. This is discussed more fully by Wilson in ref. 8.

This effect was recently observed in these laboratories during the course of an investigation on the rifling by cold-forming of small-calibre gun barrels. Some work was thereafter initiated to study the effects of steel composition on work-softening, and it is felt that some early results might be of interest.

The testing method used is very rapid. Rough machined specimens of the steels are quenched and tempered according to normal procedure for these steels. Flat-tapered tensile specimens are then finish-machined and fine lines scribed every 2 mm. on one of the large faces. The whole range of strains is thus obtained in one single pull test. The strains are determined by measuring the distance between the scribed lines after deformation. The Vickers hardness is determined at the centre of the areas enclosed by the scribed lines.

Three steels have been used so far: *AISI* 4340, 'Hy-Tuf' and Type 420 stainless steel. The compositions are given in Table 1.

An alloy steel (*AISI* 4340) was first chosen, to compare results with those obtained previously[2] on a carbon steel. The second steel was chosen mainly because of its high silicon content and of the effects of silicon in retarding the precipitation of carbides during tempering. It was thought that this could affect the work-softening phenomenon at various temperatures. Finally, Type 420 stainless steel was

Table 1

	C %	Mn %	Si %	Cr %	Ni %	Mo %
AISI–4340	0·38– 0·43	0·60– 0·80	0·20– 0·35	0·70– 0·90	1·65– 2·00	0·20– 0·30
'Hy-Tuf'	0·25	1·30	1·50	—	1·80	0·40
Type 420 Stainless	0·30	1·25	—	13	—	—

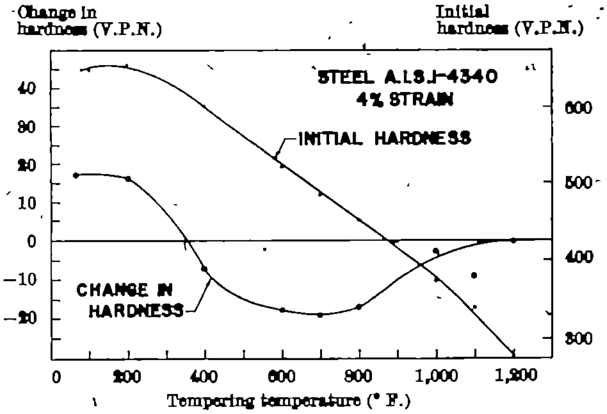

Fig. 1

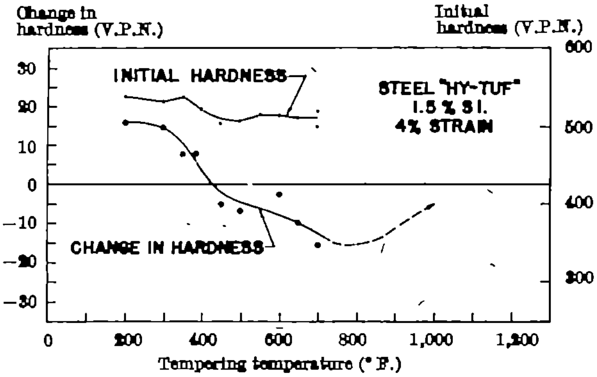

Fig. 2

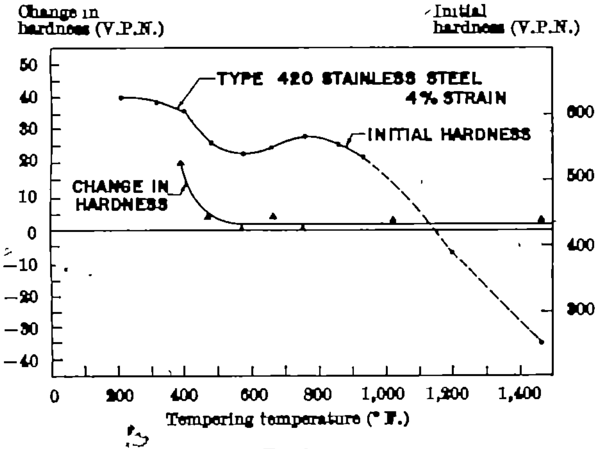

Fig. 3

included because it shows a strong secondary hardening phenomenon. In this way the same hardness can be obtained after three different tempering temperatures, that is, possibly under three different stress systems, and it was thought that the results would be instructive.

In the three steels tested, tempering temperatures below 300–400° F. produced no work-softening. On the contrary, work-hardening was obtained although, on the basis of internal stresses alone, a severe work-softening effect should be expected. Polakowski has recently proposed[9] that a concomitant phenomenon may be taking place during the deformation of martensite, namely, an extremely high strain-hardening rate of the martensite, that would mask the softening effect.

The first point of zero change in hardness occurs at a slightly higher temperature in 'Hy-Tuf' than in 4340 (Figs. 1 and 2), while the temperature of maximum softening probably remains approximately the same, that is, 700° F. (370° C.). The amount of work-softening seems to be slightly less in 'Hy-Tuf', and this may be due to the retardation in softening during tempering.

Type 420 stainless steel, on the contrary, shows no work-softening at all (Fig. 3). At equal hardnesses, obtained after tempering at 500, 675 and 875° F., no work-softening was observed and no difference in behaviour was obtained in spite of the difference in the internal stress systems present after the three different treatments.

In view of these latter results, it seems that the generally observed effect of softening in quenched and tempered steels after deformation may not be a function of the presence of internal stresses only, as has been believed previously, but that a concurrently active phenomenon is taking place to mask the work-softening effect. This may be a precipitation mechanism, and it is hoped that future work along these lines, including the determination of distribution and size of carbide particles in these steels and the correlation of work-hardening coefficients with amounts of retained austenite, will prove fruitful.

Structure of the Crust under the Eastern Mediterranean Sea

The recent disastrous shocks in southern Turkey (April 24, 1957, 19–10–05, 36° N., 28·5° E., and April 25, 1957, 02–25–36, 36·5° N., 29° E.) produced very strong *Lg* and *Rg* waves on the Benioff vertical seismometer at Lwiro (2° 15′ S., 28° 48′ E.). The shock of July 9, 1956, 03–11–39, 37° N., 26° E., also produced very strong *Lg* waves.

Because of the very short periods (about 1·5 sec.) and the gradual build-up of amplitudes, the times of arrival of *Lg* on the short-period (0·25 sec.) galvanometer (*Z*) are up to 60 sec. earlier than those on the long-period (25 sec.) one (*X*). *Rg* is only clear on *Z* and for the shock of April 25, 1957.

The velocities are: for *Lg*, on *Z*: 3·65 ± 0·04 km./sec.; on *X*: 3·53 ± 0·02 km./sec.; for *Rg*, on *Z*: 3·29 km./sec.

This is the first time that these waves have been identified after a fairly long submarine path. Their large amplitudes on the records of these shocks is in contrast to their absence or very small amplitudes on records of shocks in Greece.

It is suggested that this indicates a difference between the structure of the bottom of the Mediterranean Sea south of Greece and that south of Turkey. The exact nature of this difference and its important geotectonic implications would appear to make seismic refraction work at sea desirable in these areas.

Water Metabolism in the Sheep

Some sheep appear to pass consistently lower urine volumes than others, and during metabolism-cage experiments with *HK* and *LK*[1] Scottish Blackface sheep there was a suggestion that within each of these two groups there was much more variation between animals than between repeated observations on the same animal, and that, on the whole, urine volumes from *LK* animals tended to be lower than those from *HK* animals. The results of an analysis of the results from fifteen trials involving 19 *LK* and 17 *HK* animals are given below. Four or six animals were used per trial and equal numbers of *LK* and *HK* were used in all except three trials. The animals were in the cages for 10, 20, 32 or 93 days in each trial. A standard ration of hay and concentrates (oats and linseed meal) was fed throughout, and a sodium chloride supplement was given in all except three trials, but this did not have a marked effect on urine output.

The mean volume of urine excreted daily was found to be significantly lower for *LK* than for *HK* sheep ($P < 0.01$). The difference can be seen most readily by studying the frequency distribution of the average results for individual sheep (Table 1) and, although there is considerable overlap, the mode for *LK* sheep (approximately 500 ml./day) is clearly lower than that for *HK* sheep (approximately 700 ml./day). In addition there are a number of high values for the *HK* sheep. Because of the skewed nature of the distributions, median values rather than mean values give a more accurate idea of the difference.

The means for the volumes of water consumed and urine excreted daily followed each other closely, and the value for fæces water plus insensible loss therefore remained constant (Table 2).

Table 1. Sheep Urine Volumes per Day Frequency Distribution

Range of values (ml./day)	Numbers of sheep *LK*	*HK*
151–250	1	
251–350	2	
351–450	1	1
451–550	8	1
551–650	3	2
651–750	1	5
751–850	1	2
851–950	1	
951–1,050		
1,051–1,250	1	1
1,251–1,450		1
1,451–1,650		
1,651–1,850		2
1,851–2,050		
Over 2,050		2
Median value (ml./day)	524	734

Table 2. Mean Water Intake and Urine Volumes in *LK* and *HK* Sheep

	Mean water intake (ml./day)	Mean urine volume (ml./day)	Mean fæces water and insensible loss (ml./day)
LK	1,845	552	1,293
HK	2,459	1,073	1,386
Difference	614	521	93

Within both the *LK* and the *HK* groups, the differences between mean values for the daily urine output for different sheep were significantly greater than the differences between repeated observations on the same sheep ($P < 0.001$). For those sheep which spent three separate periods in the cages, the mean range of the three values was 173 ml./day for *LK* sheep and 478 ml./day for *HK* sheep.

These results show that considerable variation in water metabolism exists between sheep, and that although part of this variation appears to be related to the potassium type of the red blood cells, other factors are also involved. A study of the mode of inheritance of these other factors would be of value particularly in relation to sheep populations subjected to periodic droughts or kept in semi-arid environments.

Changes in the Intestinal Mucosa of the Sheep following Death by Humane Killer

In the course of an investigation of the changes in composition of the digesta along the alimentary tract of the sheep[1], it was noted that there was a considerable addition of nitrogen to the chyme in the most proximal quarter of the small intestine. The nitrogen content in the remaining quarters fell off distally until the abomasal level was attained in the fourth quarter. It was noted from *in vivo* studies on fistulated animals, and in those with exteriorized loops of the small intestine within the first two feet or so of the pylorus, that this addition of nitrogen did not occur to the same extent as in the shot sheep. Lignin was used as a reference substance to assess these changes.

A comparison of the histology of the mucosa of the small intestine (obtained practically immediately after death) of sheep shot in the frontal region with a captive bullet fired from a humane killer, and then bled, with specimens removed from sheep under pentobarbitone anæsthesia revealed that whereas the mucosa remained intact when removed under this form of anæsthesia, there was a very marked shedding of the epithelium and a loss of material from Brunner's glands, giving a positive reaction with periodic acid–Schiff (Fig. 1) in the animals which had been shot and bled—the normal method of slaughter. These differences were naturally paralleled to some degree by corresponding differences in the nitrogen content of the digesta, but there was still some rise in nitrogen content in the proximal section of the anæsthetized group and this is being further examined. It was thought advisable to bring to the attention of all those who work on the intestinal wall and on intestinal

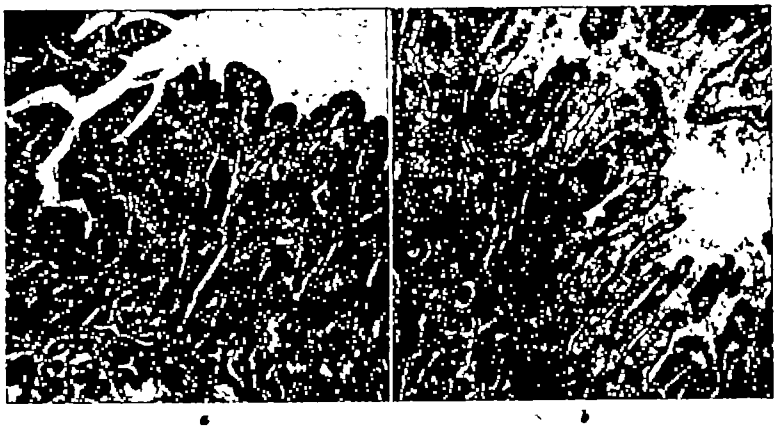

Fig. 1. Section of duodenum. Periodic acid–Schiff hæmalum (× 33). *a*, sheep anæsthetised; *b*, sheep shot and bled

contents this very marked shedding of the epithelium —mainly in the first quarter—and its elimination by removing the specimens under pentobarbitone anæsthesia. This finding has also been confirmed in the rat.

Contamination of Stock Lines of Human Carcinoma Cells by Pleuropneumonia-like Organisms

During January and February 1957 it was noticed that a line of human carcinoma cells (strain HeLa[1]) maintained in this laboratory was not growing normally. The cells failed to form continuous sheets on the glass surfaces of the culture bottles, and after 10–14 days growth the cultures had macroscopic 'moth-eaten' areas at the edges in which the cells were rounded and degenerate. The tissue culture medium was 80 per cent Eagle's basal medium[2] and 20 per cent pooled human serum, and contained 80 units penicillin and 80 μgm. streptomycin per ml. When samples of tissue culture medium in which cells had been grown were seeded into nutrient broth, faint turbidity developed after two days incubation at 37°, but no micro-organisms were found in preparations stained by Gram's method. 5 per cent horse blood agar plates similarly seeded developed colonies, 0·5 mm. or less in diameter, after four days aerobic incubation at 37°. It was then suspected that the tissue cultures might be contaminated with pleuropneumonia-like organisms; when samples of used culture fluid were seeded on to solid medium suitable for the growth of pleuropneumonia-like organisms[3], colonies with a morphology typical of these organisms grew after three days aerobic or anaerobic incubation at 37°. The colonial appearances were maintained during repeated subculture on this medium, in the absence of penicillin and thallium acetate. The organisms could not be isolated from fresh tissue-culture medium. Successive HeLa cell subcultures yielded profuse growths of pleuropneumonia-like organisms which seemed to multiply in association with the cells, since it has been shown that the organisms do not survive for more than 2 or 3 days in the tissue culture medium employed (Blyth, W., unpublished observations).

HeLa cell cultures from other laboratories were tested for pleuropneumonia-like organisms (Table 1). All these lines originated directly or indirectly from Laboratory *A*, which received the cells from Dr. Syverton in 1953. Of eight sublines of cells maintained in Laboratory *A*, only one (here referred to as *A*8) was free from contamination, and this had been maintained separately from the others by one worker. It is also noteworthy that the three lines of cells from which pleuropneumonia-like organisms could not be isolated (Line *A*8, and those from Laboratories *E* and *F*) had all at some time been propagated in the presence of aureomycin, terramycin or neomycin. It is known that pleuropneumonia-like organisms are markedly sensitive to antibiotics of the tetracycline group[4,5]. At Laboratory *F*, the cells were always grown in the presence of neomycin, 50 μgm./ml. A culture of this line, adapted to grow in horse and rabbit serum, was returned to Laboratory *A* in January 1957, and was then propagated without neomycin for some months. On examination it was found to be contaminated (Line *A*3). It is not yet clear whether this is due to a fresh contamination, or to unmasking of a latent infection by withdrawal of neomycin.

Strains of pleuropneumonia-like organisms isolated respectively from HeLa cells grown at the Lister Institute, Laboratory *A* and Laboratory *B*, were shown by complement fixation tests to be antigenically similar to strains of pleuropneumonia-like organisms isolated from human genital infections. As with the human genital strains, there were some cross-reactions with antisera to a strain of organisms isolated from a rat, to a saprophytic strain (Laidlaw *A*) and to the organism of pleuropneumonia of cattle, but the titres were much lower than those of the homologous antigens.

It therefore appears that stock lines of HeLa cells are liable to contamination by pleuropneumonia-like organisms. In the United States, Robinson, Wichelhausen and Roizman[6] showed that three out of five lines of HeLa cells, and a line of human conjunctival cells, were similarly contaminated. They suggested that contamination was probably introduced through

Table 1. Isolation of Pleuropneumonia-like Organisms from Lines of HeLa Cells maintained in Various Laboratories

Laboratory	Cell line derived from	Cell lines contaminated/ cell lines tested
A	Syverton, 1953	7/8
B	Lab. *A*, 1955	1/1
C	Lab. *A*, 1956	1/1
D	Lister Institute, 1957	1/1
E	Lab. *A*, 1954	0/1
F	Indirectly from Lab. *A*, 1955	0/1
Lister Institute	Lab. *B*, 1956	1/1

some common constituent of culture media. Since all the cell lines tested have been grown at some time in the presence of human serum, this component might be responsible, although line *A*3 was not grown in human serum at Laboratory *A* between its arrival from Laboratory *F* and isolation of pleuropneumonia-like organisms two months later. I have found that when a large number of organisms are added to human serum, a few organisms survive heating at 56° for 1 hr., so that the customary inactivation of serum by heating at this temperature for 30 or 60 min. is not a certain safeguard against contamination. An alternative hypothesis is that pleuropneumonia-like organisms were present in this cell strain when it was originally isolated from a carcinoma of the cervix. Pleuropneumonia-like organisms occur with moderate frequency in the female genital tract, particularly when disease is present[6].

The relationship between the morphological changes in the Lister Institute HeLa cells and the presence of pleuropneumonia-like organisms is being investigated; Laboratory *C* reports similar changes, but these have not been observed in other laboratories maintaining infected cell lines.

I wish to thank Miss Dorothy Card for the complement fixation tests, and Mrs. E. Klieneberger-Nobel for her interest and advice. I am also greatly indebted to the workers in the various laboratories who provided me with cultures of HeLa cells, and with much helpful information about them.

Evidence of a Second Fœtal Hæmoglobin in the Newborn Goat

Recently, some reports have appeared suggesting the existence of an embryonic human hæmoglobin which shows slight differences as compared with the fœtal hæmoglobin of the newborn child. Using an alkali denaturation technique, Drescher and Künzer[1] and Allison[2], for example, obtained evidence that the hæmoglobin present in early fœtal life is different from the fœtal and adult hæmoglobin types. Recent investigations of Halbrecht and Klibanski[3] have shown the existence of an embryonic human hæmoglobin which migrates more slowly in paper electrophoresis than the fœtal hæmoglobin from the cord blood of a newborn child. Studying the problem of fœtal hæmoglobin in newborn goats we obtained evidence that in this animal also two different fœtal hæmoglobins occur, which, however, are still present after birth.

Using an alkali denaturation method[4], it was found that the hæmoglobin of the newborn goat consists of two different components, one with a low resistance against alkali and a second with a much higher resistance against alkali (Fig. 1). As the hæmoglobin with low alkali resistance disappears slowly after birth (Fig. 1), while in the blood of the adult goat only the alkali-resistant component is present (Fig. 1), it is obvious that the hæmoglobin of low alkali resistance is of fœtal origin. About 60 per cent of this fœtal hæmoglobin was found present in a goat one day old.

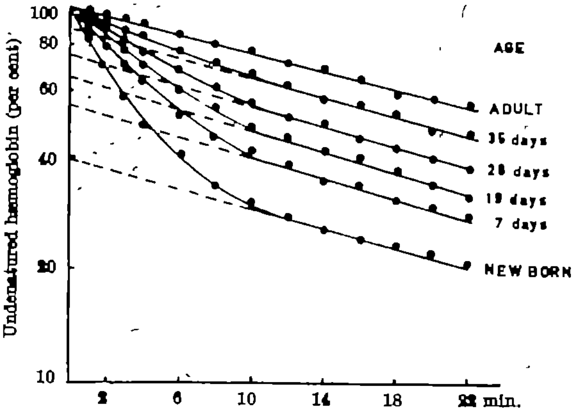

Fig. 1. The alkali-denaturation curves of the hæmoglobins of a newborn goat at different times after birth and of an adult goat

With moving-boundary electrophoresis, paper electrophoresis in a 0·06 *M* barbital buffer *p*H 8·6 and also with chromatography on 'Amberlite *IRC*50'[5], however, the hæmoglobin of the newborn goat behaves as a single component which moves faster than the hæmoglobin of the adult animal. The results of the moving-boundary electrophoresis are given in Fig. 2; the patterns obtained by paper electrophoresis and by chromatography are of the same kind. A few days after birth a second hæmoglobin was found to appear and has the same mobility as the adult hæmoglobin of the goat. The percentage amount of this component gradually increases with time and is about 90 per cent in a goat five weeks old.

Table 1 shows the analytical results obtained by studying blood samples taken at different times after birth with alkali denaturation and electrophoretic techniques. A comparison of the results of these analyses makes it likely that a second fœtal hæmoglobin is present in the newborn goat, which behaves like the adult component with respect to the alkali resistance and like the fœtal hæmoglobin regarding its electrophoretic and chromatographic behaviour. It will be seen from the quantitative data given in Table 1 that about three weeks after birth no significant amount of this second fœtal hæmoglobin could be demonstrated. The fœtal hæmoglobin with low alkali resistance, however, is still present to about 30 per cent at the same time and

has scarcely disappeared after about six weeks. The relatively fast disappearance of the fœtal hæmoglobins suggests that the survival-time of the erythrocytes of the newborn goat is fairly short. Studying the survival-time of these erythrocytes with chromium-51 and the synthesis of the fœtal hæmoglobins after birth with iron-59, we obtained values for the survival of the red-blood cells of the newborn goat varying between 25 and 30 days (in published work).

This investigation was supported by a grant from the Dutch Organization of Pure Research (Z.W.O.).

Bacterial Protoplasts from *Bacillus* Species by the Action of Autolytic Enzymes

WHEN certain bacteria are suspended in sucrose solution of suitable concentration and incubated with lysozyme, the rigid cell-walls are dissolved away, leaving relatively stable spherical protoplasts[1]. Lytic enzymes which dissolve the isolated cell-walls of vegetative *Bacillus cereus* have been found in extracts of mechanically disintegrated resting spores[2] and partial autolysates of sporulating cells[3] of this organism. When heat-treated, intact vegetative cells were treated with preparations of these enzymes, the walls were dissolved, leaving the coagulated cell-contents apparently unchanged. It has now been found that when viable organisms are suspended in sucrose solution and treated with these enzymes, relatively stable protoplasts are obtained in good yield.

The method used for the preparation of highly active cell-free solutions of lytic enzymes from sporulating cells of *B. cereus*[3] has been successfully applied to other members of the *Bacillus* group which sporulate readily in suitable liquid medium. For example, washed cells of *B. megaterium*, showing intracellular spore formation at an advanced stage, were suspended in 0·05 *M* citric acid + 0·1 *M* sodium phosphate buffer (*p*H 5·0) at a concentration of about 20 mgm. dry weight/ml. and incubated in the presence of toluene for 2 hr. at 37°. During incubation, vegetative cell material dissolved and free spores were released. A cell-free solution prepared from the autolysate contained lytic enzymes which rapidly dissolved the isolated cell-walls of this organism. Although enzyme preparations from *B. cereus* and *B. megaterium* showed optimum activity against a substrate of cell walls at *p*H values near 4·5 and 7·5, stable protoplasts were more readily obtained from both organisms when they were incubated with the enzyme at *p*H 7–7·5 in the presence of sucrose and cobalt ions. Cultures of the two organisms were grown in tryptic meat broth for 12–18 hr. on a shaker at 37° and the cells were harvested by centrifugation. The bacteria were washed with McIlvaine's buffer (*p*H 7·0) and resuspended in this buffer at a concentration of about 10 mgm. (dry weight) cells/ml. Buffered suspension (0·2 ml.) was mixed with enzyme solution (0·5 ml. derived from about 10 mgm. sporulating cells), cobalt sulphate solution (0·1 ml. ≡ 50 μgm. Co^{++}), sucrose (50 mgm. ≡ 0·2 mole) and incubated at 37° in parallel with a control suspension without enzyme. After 20–60 min., the rod-shaped bacilli in the enzyme-treated suspension were completely replaced by spherical protoplasts (Fig. 1), whereas no change occurred in the control. Counts made in a Helber 'Hellige' chamber of the protoplasts and bacilli in

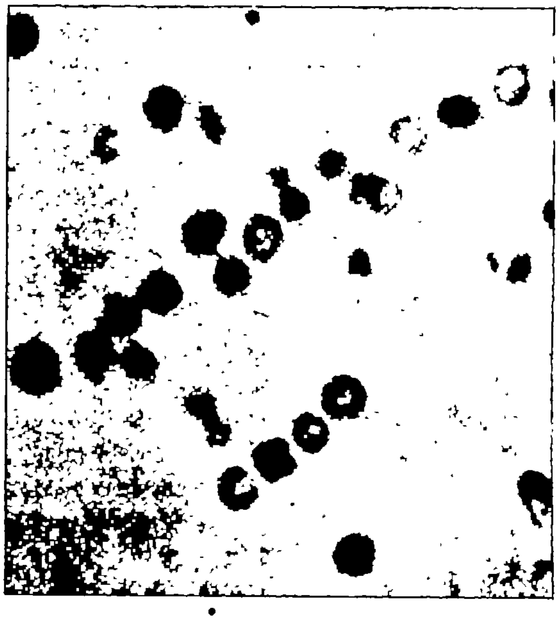

Fig. 1. Protoplasts of *Bacillus cereus*. × 2,000. (A trace of crystal violet was added to the suspension)

the enzyme-treated and control suspensions respectively indicated that recovery of protoplasts was good. Suspensions were stable for at least 24 hr. at room temperature but the structures disintegrated on dilution with water.

Enzymes from sporulating cells of a given *Bacillus* species usually attacked the isolated cell-walls from certain other members of the group but were most active against a substrate of cell-walls from the same organism. For the preparation of protoplasts, autolytic enzymes from sporulating cells of the same organism were used. Such enzymes may prove useful for the preparation of stable protoplasts in cases where the organism is relatively insensitive to the action of lysozyme. Using the conditions described by Weibull[1], we obtained protoplasts in good yield from *B. megaterium*, whereas, using the same concentration of crystalline lysozyme (600 μgm./ml.), the number obtained from *B. cereus* was very small.

Effects of Gamma-ray Irradiation on Nematodes infesting Cultivated Mushroom Beds

During a discussion with Dr. H. J. M. Bowen, of the Technological Irradiation Group of the United Kingdom Atomic Energy Authority, it was suggested that the effect of gamma-ray irradiation on the nematodes present in compost from infested mushroom beds be determined. Accordingly, 1 cwt. of infested mushroom compost was obtained from a commercial farm, and from representative samples the nematode content, on January 22, 1957, was determined, by the standard technique of extracting 100 gm. of compost for 24 hr. on a Seinhorst 'Mistifier'[1] as:

Ditylenchus destructor	436,000
Saprobes, mostly *Rhabditis* spp	964,000

Duplicated 200 gm. samples of this infested compost were sealed in polythene bags and sent to the Wantage Radiation Laboratory, where (with the co-operation of the Technological Irradiation Group) they were exposed to gamma radiation from cobalt-60 at a dose-rate of 120 rep/minute. The samples received doses of 6,000, 12,000, 24,000, 48,000 and 96,000 rep, on January 17, 1957.

(A rep—roentgen equivalent physical—is the 93 ergs/gm. deposited on irradiated material, assuming unit density.)

Nematodes in the irradiated compost were counted on January 30, 1957, with the following results:

Treatment	Nematodes/100 gm./24 hr.	
	D. destructor	Saprobes
Control	87,000	414,000
12,000 r.	94,500	315,000
24,000 r.	76,500	253,000
48,000 r.	109,500	267,000
96,000 r.	108,500	166,000

The population of *D. destructor*, in the control as well as in the treated samples,[2] has dropped below the pretreatment count. The population of saprobes in the control also fell but with them there was a further continuing diminution with increasing radiation dose.

The work of Fassuliotis and Sparrow[3] suggests that the reproductive capacity is affected by gamma radiation. Assuming this to be so, it appears possible that the fall in numbers of *D. destructor* results from lack of mycelium food material in the compost and not from irradiation, the effects of which are not yet showing because the reproductive cycle of *D. destructor* is relatively long (about 3 weeks). With the saprobes, on the other hand, the reproductive cycle is short (48 hr. for this *Rhabditis* sp.) and, as bacterial food was plentiful, the failure to reproduce may already be showing at the higher doses.

From each sample of irradiated compost nematodes were washed out on an extractor and about a hundred *D. destructor* picked out, then washed with 5 ml. of sterile water into spawn jars filled with sterilized compost, which was inoculated nine days previously with pure culture mushroom mycelium. The inoculated jars were duplicated and kept at laboratory temperature, one series for six weeks, the other for ten weeks.

Examination of the first series after six weeks gave the following results:

	Radiation dose	*D. destructor* in 100 gm./24 hr.
About 100 *D. destructor* inoculated per jar	Control	5,900
	6,000 r.	2,100
	12,000 r.	3,500
	24,000 r.	1,500
	48,000 r.	10
	96,000 r.	2

At this stage the nematodes in the compost receiving the highest two doses were all adults and the females contained no eggs. It appeared, therefore, that nematodes had reproduced in all samples except those receiving the 48,000 and 96,000 r. doses.

After ten weeks the results were:

	Radiation dose	*D. destructor* in 100 gm./24 hr.
About 100 *D. destructor* inoculated per jar	Control	1,070,000
	6,000 r.	388,000
	12,000 r	2,425,000
	24,000 r.	43,200
	48,000 r.	8,500
	96,000 r.	0

In the meantime other samples of the irradiated compost were extracted and from them two series of twenty *Rhabditis* were hand-picked and cultured, at 25° C., on plates of Nigon's[4] agar sown with yeast. After six days one series of plates was extracted in a Baermann funnel for 24 hr. and the nematodes counted. The results were:

	Radiation dose		*Rhabditis*/plate
20 *Rhabditis* inoculated per plate	*A*	Control	49,500
	B	12,000 r.	14,250
	C	24,000 r.	3,425
	D	48,000 r.	3 alive; 1 dead
	E	96,000 r.	1 dead

After a further six days the second batch of plates was extracted with the following results:

	Radiation dose		*Rhabditis*/plate
20 *Rhabditis* inoculated per plate	*A*	Control	125,600
	B	12,000 r.	75,750
	C	24,000 r.	41,200
	D	48,000 r.	2,000
	E	96,000 r.	0

The inactivation dose for the two species of nematode examined appears to lie between 48,000 and 96,000 rep, more than twice as great as the 10,000 and 20,000 r. Fassuliotis and Sparrow[2] found to inactivate cysts of potato-root nematode (*Heterodera rostochiensis*).

Simultaneous Synthesis of Two Inducible Enzymes in *Staphylococcus aureus*

The problem of inducible enzyme synthesis is currently receiving much attention because of its obvious value in the study of protein and nucleic acid formation and their interrelationship[1].

Studies conducted to date have been confined to single systems, and to our knowledge, little is known concerning the effect of one inducible system upon another under conditions favouring simultaneous induction of both. For this reason, we have compared the induction of nitrate reductase and β-galactosidase singly and together in *Staphylococcus aureus*. Nitrate reductase is an inducible enzyme in this organism, and demonstrates many of the characteristics described by Pollock and Wainwright[2] for the *Escherichia coli* system. β-Galactosidase has been shown by Creaser[3] to be an inducible enzyme in *Staphylococcus aureus*.

Induction of both enzymes was carried out according to the method of Creaser[3], with the exception that anaerobic conditions were used throughout. In the presence of 1 per cent galactose, β-galactosidase is formed after a lag period of approximately 30 min. In the presence of 1 per cent potassium nitrate, nitrate reductase is formed rapidly with little or no lag. These results are shown in Fig. 1, where the term 'single' is used for describing induction in the presence of the homologous inducer. The term 'dual' in Fig. 1 refers to the rate of enzyme formation when both inducers are present from zero time. It may be seen that under conditions where both enzymes are synthesized, a mutual stimulation occurs. That is, in the presence of nitrate and galactose, both nitrate reductase and β-galactosidase are synthesized at a more rapid rate and a higher total amount of enzyme is formed. This experiment has been reproduced a number of times. Further, it has been found that subsequent addition of the second inducer to either system after allowing single induction to proceed for 15–30 min. also results in increased production of both enzymes.

One possible explanation of these results is that galactose stimulates nitrate reductase by providing an additional carbon source and also by creating an additional demand for an electron transport system. However, the addition of glucose to a final level of 1 per cent in the nitrate system resulted in a slight inhibition of nitratase formation. The stimulation of β-galactosidase by nitrate might also be explained on the basis that nitrate reductase provides an electron transport system which allows more rapid dissimilation of galactose. Attempts to examine this possibility by substituting methylene blue and ferricyanide for nitrate were without success since these agents interfered with the colour test used for measuring β-galactosidase.

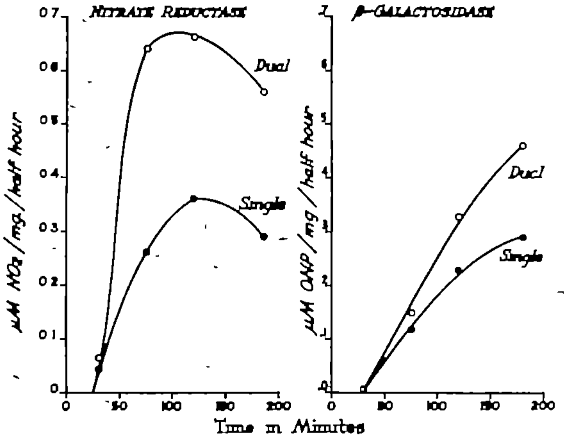

Fig 1. Synthesis of nitrate reductase and β-galactosidase in the presence of homologous (single) and homologous plus heterologous (dual) inducers. See text and ref. 3 for details.

Under conditions of dual induction, decreasing the amino-acid concentration from 0·2 to 0·1 per cent suppressed β-galactosidase synthesis to a greater extent than nitrate reductase. These results are in accord with those of Wainwright and Neville[4], who attributed this difference in response to an ability of the organism (*E. coli* in their experiments) to utilize the reduced nitrate as a source of nitrogen. It might also be noted that Wainwright and Neville also found that tetrathionase induction appeared to stimulate induction of β-galactosidase; however, no results were shown. Studies are now under way to determine what priority, if any, may exist in the dual induction system under limiting conditions. These and other results will be published in detail elsewhere.

A Photometric Method for Avian Liver Xanthine Dehydrogenase

A photometric method for chicken liver xanthine dehydrogenase based on the colorimetric determination of substrate disappearance[1] has been developed. It has been demonstrated to be very sensitive by comparative measurements of liver xanthine dehydrogenase using the manometric technique[2] during protein depletion and repletion.

Livers from thoroughly exsanguinated birds were removed immediately and chilled on ice. A portion was homogenized[1] and centrifuged at 24,000*g* for 40 min. at 0–3° C., yielding a clear supernatant. Use of a supernatant fraction in lieu of homogenate

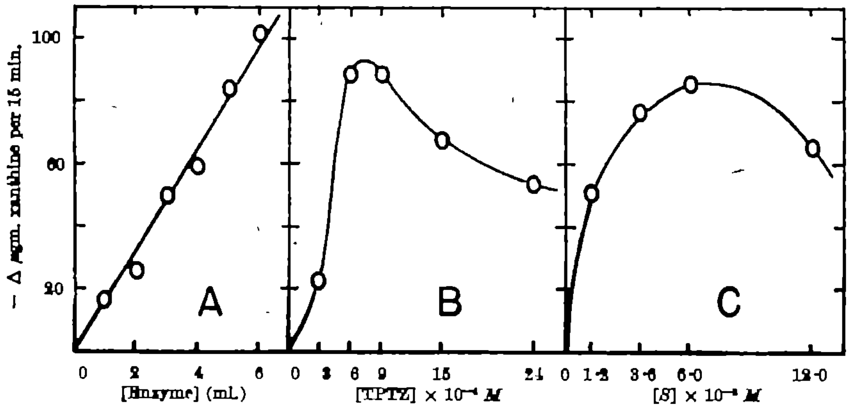

Fig. 1. Effect of enzyme, substrate and triphenyltetrazolium chloride concentration on liver xanthine dehydrogenase activity in the chick

improved the rate and uniformity of the catalytic reaction, eliminating about 35 per cent of the endogenous colour-forming material. Recovery of the added substrate at zero time averaged 97 per cent compared to 80 per cent using homogenates. Fig. 1,*A* demonstrates linearity between enzyme concentration and activity.

For reoxidation of the dehydrogenase[3], methylene blue[2] could not be used because of interference with the colorimetric determination of substrate; therefore, triphenyltetrazolium chloride, which is colourless under the assay conditions, was employed. Triphenyltetrazolium concentration is optimal at $7 \cdot 3 \times 10^{-4}$ *M* (Fig. 1,*B*). To link liver xanthine dehydrogenase to lactic dehydrogenase[4], oxidized diphosphopyridine nucleotide (5×10^{-3} *M*) was tested in the system. This addition was not considered essential since liver xanthine dehydrogenase activity of normal and depleted livers was equally improved (about 30 per cent).

To determine enzyme activity, stoppered 25-ml. Erlenmeyer flasks containing 5 ml. supernatant, 0·5 ml. triphenyltetrazolium (0·01 *M*) and, after a 10-min. pre-incubation period, 0·6 ml. xanthine solution (0·038 *M*) or water (control flasks) were shaken in a Dubnoff shaker at 37° C. at 190 oscillations per min. A final substrate concentration of $3 \cdot 6 \times 10^{-3}$ *M* was chosen. This level maintains approximately optimum activity during a 30-min. test (Fig. 1,*C*), whereas higher concentrations require extensive dilution of the aliquots for colorimetric assay.

After addition of substrate, each of the reaction mixtures was thoroughly shaken and a 1-ml. sample withdrawn within 10 sec. (zero time reading) and at 7·5, 15, 22·5 and 30 min. The reaction was rapidly stopped by pipetting the aliquots directly into 7 ml. of 40 per cent sodium tungstate, 2 *N* sulphuric acid and water (1 : 1 : 5). After 15 min. these tubes were diluted to 12 ml. with water and the concentration of xanthine determined[1]. Xanthine values obtained for the test flasks, corrected for endogenous activity (control flasks), are plotted against time. Comparable enzyme activity is calculated from the zero-order portion, which usually extends to 15 min. and is expressed by − Δ μgm. xanthine per 15 min.

Four-week old Lancaster and Columbian–New Hampshire chicks were used in a depletion–repletion study. They were raised on a commercial chick starter ration and then changed to a casein (7 or 21 per cent), fortified with glycine, arginine and methionine at 0·4, 0·2 and 0·04 per cent, 'Cerelose' diet adequately supplied with all known dietary essentials. At the start all birds received the control diet (21 per cent protein) for 4 days. Thereafter one group was changed to the 7 per cent protein diet. Enzyme activity was assayed on days indicated (Fig. 2). Body-weights of all birds were recorded at the beginning of the depletion period and at killing. Liver supernatant nitrogen was determined using semi-micro-Kjeldahl technique in duplicate.

Changes in liver xanthine dehydrogenase activity expressed on a nitrogen basis and body-weight are presented in Fig. 2, *A* and *B*. A comparison of liver xanthine dehydrogenase reduction in the bird with the behaviour of rat liver xanthine oxidase[5,6] shows the former to be less rapid and less extensive. About 40 per cent of total activity is lost during the first 4 days on a low protein diet, followed by an additional 25 per cent decrease in the next 10 days. When the higher protein-level is restored, enzyme activity is regained promptly. After 10–14 days of depletion, enzyme activity and growth are inhibited to about the same extent.

Supernatant enzyme activity determined manometrically[3] (Fig. 2, *A*) shows close agreement with

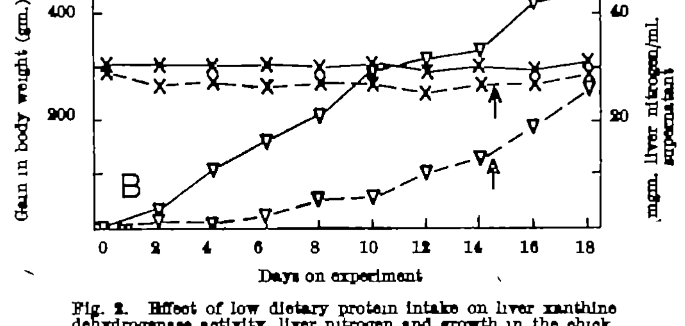

Fig. 2. Effect of low dietary protein intake on liver xanthine dehydrogenase activity, liver nitrogen and growth in the chick. ○, Enzyme activity determined colorimetrically; ●, enzyme activity determined manometrically; ▽, body-weight gain; ×, liver nitrogen. Solid lines represent the control group (21 per cent protein), broken lines the depleted group (7 per cent protein). The arrow indicates the point of repletion

the colorimetric method during depletion but seems less sensitive during repletion.

Xanthine Oxidase Activity during Mammary Carcinogenesis in Mice

SOME hypothetical and empirical considerations that form the basis of our interest in xanthine oxidase have been stated in the first of a series of publications[1]. The investigations of the chemical properties of xanthine oxidase[1-3] have been extended to include the biological behaviour of this enzyme in normal and abnormal growth. The present communication deals with the xanthine oxidase activity in mammæ of mice of the C strain, with and without the milk factor, and in spontaneous mammary tumours. The studies of the enzyme activity in mammæ during pregnancy and lactation will be reported elsewhere.

The mice of the C strain without the milk factor will be referred to as C–. A sub-line of these mice (C+) was developed by incorporation of the milk factor through foster-nursing. The tumour incidence in C– virgins and breeders is practically nil, whereas the tumour incidence in C+ mice, while low in virgins, rises progressively to 100 per cent with the number of pregnancies. The spontaneous mammary tumours assayed were obtained from the C+ breeders.

The tissues were dispersed in a Potter–Elvehjem type of homogenizer with a Teflon pestle. The suspension medium (in the proportion of 9 ml. for each gm. of tissue) for the enzyme assay was 0·1 *M* pyrophosphate buffer (*p*H 8) and for the nuclear count was a solution containing sucrose (0·25 *M*) and calcium chloride (0·0018 *M*). The homogenate in the buffer was centrifuged at 20,000*g* for 30 min. at 0° C. and the clear supernatant was removed, avoiding the upper layer of fat, and incubated for 1 hr. at 37° C.

The enzyme assay[1], a modification of Kalckar's[4] method for determining purines, consisted in the spectrophotometric estimation of the rate of appearance of uric acid in the presence of xanthine ($2 \cdot 6 \times 10^{-4}$ *M*) as the substrate. Readings were obtained for 10 min. at 1-min.-intervals at a constant temperature of 24° C. The enzyme activity was related to the cellularity of the tissue by dividing the activity per mgm. by the number of nuclei in a mgm. of fresh tissue. The nuclei were counted in a hæmocytometer after suitable dilution of the sucrose–calcium chloride homogenate in a solution of orcein-light green stain.

The results are summarized in Fig. 1, which shows the group averages and standard deviations of the enzyme activities in mammæ from C– virgin mice (group *A*), from C+ virgin mice (group *B*), and in mammary tumours from C+ breeders (group *C*). The amount of xanthine oxidized (or uric acid appearing) in micromoles × 10^{-3} per min. per 100,000 nuclei is 7·2, 4·1 and 1·8 for groups *A*, *B* and *C*, respectively. Relative to the xanthine oxidase activity in breasts from mice without the milk factor (group *A*), the activity in mammary tissue from mice with the milk factor (group *B*) is 57·7 per cent and in spontaneous mammary tumours (group *C*) 24·9 per cent. The differences of the average levels of enzyme activity are statistically highly significant, the *P* value being less than 0·001 by the *t*-test.

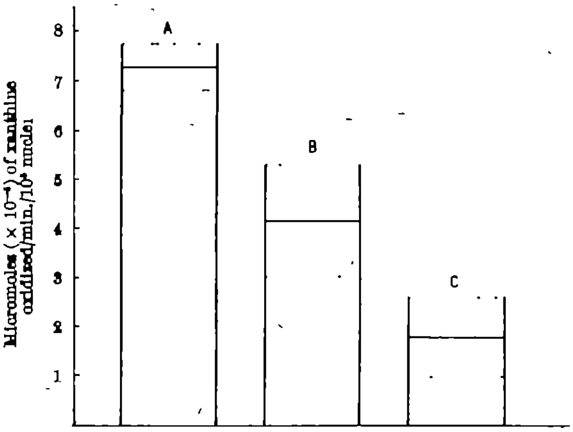

Fig. 1. Xanthine oxidase activity during carcinogenesis in mouse breast. *A*, Virgin breast from low-tumour strain (C–) without milk factor; 25 animals. *B*, Virgin breast from high-tumour strain (C+) with milk factor; 50 animals free of tumours. *C*, Spontaneous mammary tumour from mated (C+) mice; 24 animals. (Dotted line indicates ± S.D.)

It is of interest to mention that the xanthine oxidase activity in mammæ from multiparous, cancer-prone C+ breeders, whether they have or have not yet developed mammary carcinoma, is practically the same as in mammæ from C+ virgins which usually do not develop tumours. No appreciable difference in xanthine oxidase activity could be detected in livers from C– and C+ mice. In contrast to the progressive decrease in the activity of xanthine oxidase associated with the events which predispose to and finally result in abnormal growth (Fig. 1), it was found that during pregnancy the enzyme activity in the growing breast pads of C+ mice increased markedly.

The interpretation of the results shown in Fig. 1 is as yet difficult, since a number of conditions must be considered which need clarification. The activity measured by enzyme assays *in vitro* does not necessarily reflect the biological activity within the intact cell, since such limiting factors as substrate concentration, the nature and concentration of activators and inhibitors *in vivo* are not known. Moreover, the activity per cell, as here expressed, is an average value for all cells in the homogenate and does not reveal localized changes in enzyme activity. A spotty distribution of foci of cells with low or no enzyme activity surrounded by normal cells would be possible and has been reported for antigenic cell constituents[5]. Furthermore, it should be pointed out that, although the C– and C+ mice originated from the same genetic stock, prolonged inbreeding within the sub-lines may have resulted in a genetic difference. Thus, the difference in xanthine oxidase activity in mammæ of group *A* and *B* (Fig. 1) may not be due solely to the incorporation of the milk factor.

While the above considerations must be borne in mind and will lead to further experiments, the present results indicate a progressive decrease of xanthine oxidase activity during carcinogenesis in the mammæ of mice carrying the milk factor. This observation is similar to the one by Westerfeld *et al.*[6], who noted a decrease of xanthine oxidase in livers—as yet free of tumours—from rats fed a carcinogenic azo-dye. The gradual depletion of various other intracellular constituents in liver during azo-dye carcinogenesis has been reported and the degree of loss has been correlated with the degree of carcinogenicity of the compound[7–9]. Thus, the gradual decrease of xanthine oxidase activity during the changes of the normal tissue to a precancerous and eventually to a tumorous condition may be a further instance tending to support the deletion hypothesis of carcinogenesis[10,11].

We thank Profs. A. Haddow and F. Bergel for their interest and encouragement throughout this investigation, which was supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service.

The Polyhedral Virus of *Heliothis armigera* (Hbn.) (Lepidoptera : Noctuidae)

ACCORDING to Steinhaus[1], Mally[2] may have been the first to mention in 1891 a wilt disease in *Heliothis armigera* (Hbn.). Later reports of this disease came from Glaser and Chapman[3], Parsons[4], and Stahler[5]. Because of the economic importance of this insect and the possible use of the virus for control purposes it was decided to investigate the causative agent.

The larvæ used in this investigation died, presumably of a virus disease, in rearings of this insect carried out by G. Marcos at the Gezira Research Farm of the Ministry of Agriculture of the Sudan in the autumn of 1956. Two samples containing about twenty and five dried larvæ were submitted. The diagnosis with the light microscope revealed the presence of large numbers of bacteria, but only the five larvæ of the small sample showed several small polyhedra. The five larvæ were crushed and suspended in water for some weeks. This suspension was filtered through fine 'Orlon' mesh and the remnants thoroughly washed to save as many polyhedra as possible. The latter were purified by differential centrifuging. Due to the small size sample, only a few mgm. of an impure polyhedral preparation could be obtained.

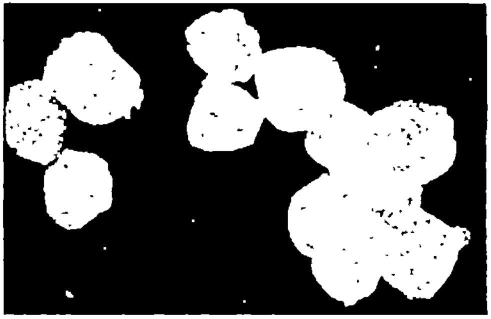

Fig. 1. Polyhedral bodies of *Heliothis armigera*. (× 10,000)

The examination of this polyhedral preparation in the electron microscope revealed that the polyhedra are of irregular shape and vary in diameter from 0·7 to 1·2μ, the majority measuring about 1·1μ (Fig. 1). Apart from these polyhedra a few smaller, ovoid forms could be observed which might be capsular inclusion bodies. However, it was impossible to decide the identity of these forms with capsules.

The virus particles were liberated from the polyhedra and purified according to the standard method[6]. However, owing to the impurity and scarcity of the sample it was not possible to determine accurately the alkali concentration necessary to obtain highly infective particles. The dissolution of 1 mgm. of polyhedra in 0·2 ml. of a mixture of 0·01 *M* sodium carbonate + 0·05 *M* sodium chloride was used. These polyhedral suspensions became rather brownish during the dissolution period of three hours, and a heavy brownish sediment of impurities resulted from sedimentation at 4,000 r.p.m. (3,000*g*) for five minutes. The slightly turbid supernatant, consisting of polyhedral protein and virus particles, was sedimented for one hour at 11,000 r.p.m. (10,000*g*). The small yellow-white sediment of virus particles was re-suspended in 0·2 ml. distilled water and again spun for one hour at 11,000 r.p.m. The final sediment was well drained and suspended in 70 μl. (one-seventh of its original volume) and diluted 1 to 5 with distilled water before applying to the electron microscope grids.

The investigation in the electron microscope showed that the virus is rod-shaped and occurs mainly in single rods (Fig. 2). It is a typical representative of classical polyhedral virus of the *Borrelina* group and the name *Borrelina armigera* is suggested. Several micrographs revealed that this virus has all the typical morphological differentiations (developmental and intimate membranes, spherical stages, etc.) characteristic of this group. There are very few virus bundles, and these contain most likely only two rods, similar to the *Bombyx mori* L. polyhedral virus. The average dimensions of the single virus rods still possessing the developmental membrane are about 320 ± 10 mμ × 90 ± 10 mμ. For technical reasons it was impossible to test the infectivity of this

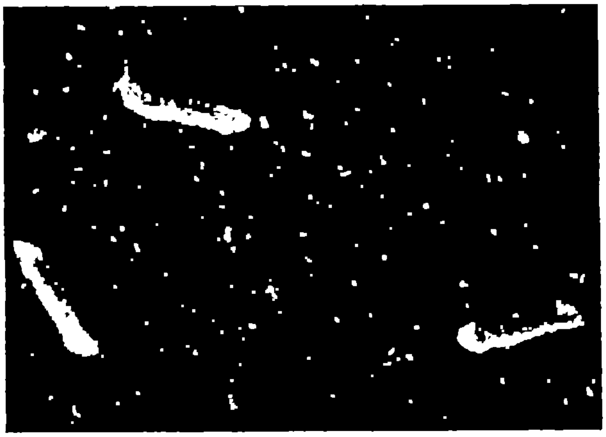

Fig. 2. Virus particles liberated from *Heliothis armigera* polyhedra. (× 50,000)

virus preparation but there is no doubt that the rods are the causative agent. The micrographs suggest further that the alkali concentration for the dissolution of the impure polyhedra was too high, since many virus particles had lost their developmental and part of their intimate membranes. It can be assumed by analogy with other viruses of this group that virus particles without membranes have lost their power to infect. It is further suggested that the proper alkali concentration for dissolution of *H. armigera* polyhedra should be less than 0·01 *M*, probably about 0·008 *M*, sodium carbonate. The lack of material did not permit us to check this point accurately.

The condition of the submitted larvæ made it impossible to decide in what tissue the polyhedra develop and whether it is a nuclear or cytoplasmic polyhedrosis. However, by analogy with other insect viruses, it is likely that the rod-shaped particles are the causative agent of a nuclear polyhedrosis. The possible presence of a granulosis is at present being investigated.

Enigmonia aenigmatica Sowerby, a Motile Anomiid (Saddle Oyster)

Among the most obscure of marine bivalves are the elongated anomiids which occur on the leaves and exposed roots of mangroves over an uncertain area in the tropical central Indo–Pacific, but certainly ranging from Malaya to the Philippines and to north-east Australia. According to Iredale[1], the original description, based on a single valve from the East Indies, is that of Chemnitz in 1795. He named it *Tellina aenigmatica*, but he was non-binomial and the earliest valid user was Sowerby, who in 1825 used the name *Anomia aenigmatica*. Later, Koch introduced the generic name, as it later turned out pre-occupied, *Aenigma*, Iredale[2] being responsible for its substitution in 1918 by *Enigmonia*. Individuals found on mangrove leaves (Fig. 1) are flat and oval; those on stems and roots are more elongate with the shell curved in the line of the long axis so as to conform with the surface. It is not known whether these are separate species or are growth forms.

Iredale[1] has summarized all that appears to be known about this animal so well named *Enigmonia aenigmatica*. Knowledge is confined to descriptions of valves; no observations on this animal in life appear to have been published. Although Allan[3] gives a drawing of a specimen on a leaf (text-fig. 66, No. 9, p. 283), yet judging from her text she relies entirely on Iredale's earlier account, the drawing not having been made from life nor, apparently, being of an animal actually attached to a leaf.

My attention was directed to the presence of this species around the coasts of Singapore Island and of Malaya by Prof. R. D. Purchon during August 1956. I failed to secure living specimens; but later my colleague, Mr. Gareth Owen, returning from New Zealand by way of Singapore, was more fortunate and collected two on mangrove leaves which I later examined alive in Glasgow. Later, Prof. Purchon sent preserved specimens, including individuals attached to stems. I am most grateful to Prof. Purchon and to Mr. Owen for this apparently first opportunity of examining alive a lamellibranch mollusc of such unusual interest.

It turns out that *E. aenigmatica* is a motile anomiid. As shown in Fig. 1, it possesses a long foot, flat and ribbon-like except for an attenuated terminal region like a filament which is pointed and round in section. This is very active and gives the impression of having tactile functions. The flattened region of the foot can extend for more than half the length of the shell; with this the animal crawls actively over the surface of a mangrove leaf as it is shown doing in the figure or, with no less facility, on the glass sides of an aquarium. In movement the foot appears to flow, the distal region (excluding the filament) spreading out and then acting as a sucker which grips the substratum while the pedal muscles, which can be seen through the translucent tissues, contract and draw the animal forward. If the shell is turned upside down the foot twists so that the sole remains on the under side; this grips the surface and eventually the animal is pulled over on to the right valve. Apart from being elongate the shell is that of a typical anomiid, that is, with the deep embayment of the mantle/shell in the under, right mantle lobe and shell valve. General disposition of the organs and the direction of ciliary currents on the ctenidia, palps and in the mantle cavity are all essentially the same

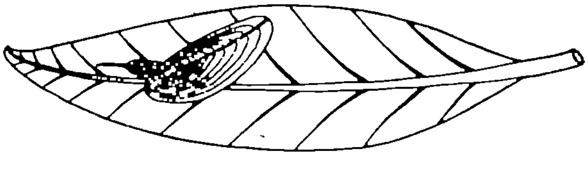

Fig. 1. *Enigmonia aenigmatica* (× ½) with foot extended crawling over mangrove leaf

as those described by Atkins[4] for *Heteranomia squamula* and *Monia squama*. Differences are in the great development of the foot with resumption of its original function, in the temporary nature of byssal attachment and in the greater modification of the shell.

Despite their immobility the foot never disappears in the anomiids, neither in byssal-attached species of *Anomia* (covering various subgenera such as the British *Heteramonia* and *Monia*) nor the window-pane shells of the closely allied genera *Placenta* (*Placuna*) and *Ephippium*, which live, immobile on the surface of mud or sand, also resting on the right valve, which has there no embayment. The foot, as in other immobile lamellibranchs where it is also retained, for example, *Spondylus*, assists in cleansing the mantle cavity. It is never lost, as it is, for example, in the Ostreacea, and there is nothing to prevent its hypertrophy and use again as an organ of locomotion in *E. aenigmonia*.

From time to time the foot was observed to withdraw. When seen through a glass surface to which the animal was attached, contact appeared then to be made by way of a sucker-like ribbed surface. Further examination showed this to be the byssal opening, and attachment to be due to secretion of a transparent byssal material. The animal has no difficulty in breaking this very temporary attachment. The condition in the specimens living upon roots and stems, where attachment does appear to be more permanent, still awaits examination.

Although lying on its side with the left valve uppermost, this bivalve, as shown in Fig. 1, has the habits and to some extent the appearance of an elongated limpet. The appearance is due to the manner in which the umbo, which represents the highest point of the shell, like the apex of a limpet, has withdrawn from the margin. This is a consequence of the extension of the mantle lobes 'dorsally' on either side of the mantle isthmus so that they surround the ligament and meet 'dorsal' to this. The ligament becomes an island connecting the two valves which extend beyond it 'dorsally' as well as 'ventrally'. The same process takes place in all anomiids but not to the same extent as in *Enigmonia*.

As in all such instances, therefore, we are seeing in *Enigmonia aenigmatica* the realization of potentialities—however far from initially apparent these may be—which are latent in the parent anomiid stock. The opportunity is being taken, when giving a fuller account of this most interesting lamellibranch, of re-investigating form in the Anomiacea.

Fixation of the Rabbit Pituitary Gland

WHILE investigating the cytology and cytochemistry of the adenohypophysis of the female rabbit, it was discovered that the fixation of whole pituitaries by immersion in the fixative was unsatisfactory. The reaction of the basophil cells to the periodic acid–Schiff procedure and to the Gram technique was extremely inconstant. It was clear that the total number of basophils was not being demonstrated and there was often much diffuse coloration of cells the exact nature of which it was difficult to determine. Commonly, also, a peripheral rind of distorted cells was produced, the staining of which was atypical.

Since serial sections of the complete pituitary were required, fixation by freeze-drying was unsuitable. In consequence, fixation by vascular perfusion was adopted. The animal was anaesthetized with nembutal given intraperitoneally (intravenous injection caused extensive cell damage, evidently owing to vascular spasm): it was then perfused into the left ventricle at a controlled pressure. Direct perfusion with a non-precipitant fixative without previous washing out of the blood gave very poor fixation. The effect of preliminary perfusion with several fluids was then compared, namely, Ringer's fluid, 0·25 *M* sucrose, saline and Ringer's solution both buffered to pH 4·5 (this being near the isoelectric point of the pituitary glycoproteins of some other species[1,2]). These were followed by perfusion with neutral formalin, formal-sublimate or Helly's fluid. None of these procedures was successful in preserving adequately the glycoprotein of the basophil cells and the general fixation of the adenohypophysis was extremely variable, areas of distorted and disrupted cells being frequently encountered. The degree of dilatation of the sinusoids also varied widely. A perfusion pressure of 80 mm. mercury was used in these experiments.

Finally we decided to use, for the preliminary washing out, a fluid more comparable physiologically with plasma but which would not be coagulated by the ensuing fixative. A commercial preparation, 'Dextraven' (6 per cent w/v dextran in 5 per cent dextrose), was employed, at a perfusion pressure of 50–60 mm. mercury. It was hoped that this would prevent loss of glycoprotein, and that there would be no serious non-specific absorption of periodic acid–Schiff positive carbohydrate from the perfusion fluid itself. We found that the distortion effects were greatly reduced, and, when 'Dextraven' was followed by a mixture of neutral formalin, calcium and cadmium chlorides, excellent preservation of the glycoprotein resulted, allowing brilliant staining by the periodic acid–Schiff technique. There was some non-specific absorption of carbohydrate in the sinusoidal lining cells, but elsewhere it was very slight and, in the acidophils, absent. It is not claimed that this method is always successful in preserving all the glycoprotein material, since it has not yet been possible to control all the variables involved: but we consider that with it a more accurate picture of the basophil cells can be obtained than by the usual method of fixation by immersion. The extent of the zona tuberalis is also more clearly defined.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Monday, October 14

British Society for the History of Science, Philosophy of Science Group (in the Gustave Tuck Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. R. O. Kapp: "Ockham's Razor and the Unification of Physical Science" (Chairman's Address).

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "The Social Consequences of Automation", opened by the President.

Royal Institute of Chemistry (at Ewell County Technical College, Reigate Road, Ewell, Surrey), at 7 p.m.—Dr. A. H. Cook, F.R.S.: "Chemical Problems in the Brewing Industry".

Monday, October 14—Tuesday, October 15

Society of Chemical Industry, London Section (joint meeting with the Chemical Engineering Group, at the Royal Institution, Albemarle Street, London, W.1), at 2 p.m. Monday and 9.30 a.m. Tuesday—Symposium on "Safety in Chemical Industry".

Tuesday, October 15

Society of Chemical Industry, Agriculture Group (at 14 Belgrave Square, London, S.W.1), at 10.30 a.m.—Phosphorus Meeting.

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. J. F. M. Middleton: "Witches and Sorcerers".*

Institution of Post Office Electrical Engineers (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 5 p.m.—Chairman's Address: "50 Years of Radio Development in the Post Office".

Institute of Physics, Electronics Group (at 47 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. B. Meltzer: "Dense Electron Beams".

Institution of Civil Engineers (at Great George Street, London, S.W.1), at 5.30 p.m.—Mr. F. L. Harwood and Mr. K. C. Wilson: "An Investigation into a proposal to Dispose of Power Station Ash by Discharging it into the Sea at Low Water".

Physical Society, Acoustics Group (in the Physics Lecture Theatre, Imperial College, Imperial Institute Road, London, S.W.7), at 5.30 p.m.—Dr. M. Redwood: "The Propagation of Compressional Waves in Solids at Frequencies between 10 and 100 Mc./sec. and the Measurement of their Absorption".

Tuesday, October 15—Wednesday, October 16

The Corrosion Convention (at the Central Hall, Westminster, London, S.W.1). (Organized by *Corrosion Technology* and the Leonard Hill Technical Group.)

Wednesday, October 16

Water Research Association (at the Royal Society of Arts, John Adam Street, London, W.C.2), at 2.30 p.m.—Discussion on the Work of the Association. Chairman: Mr. Norman J. Pugh.

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 3 p.m.—Annual General Meeting. Capt. A. M. A. Majendie: "The Display and Use of Navigational Intelligence" (Presidential Address).

Royal Meteorological Society (at 49 Cromwell Road, South Kensington, London, S.W.7), at 5 p.m.—Dr. C. H. B. Priestley: "The Work of the Division of Meteorological Physics, Commonwealth Scientific Research Organization, Victoria, Australia".

Royal Society of Medicine, Comparative Medicine Section (at 1 Wimpole Street, London, W.1), at 5 p.m.—Dr. J. B. Brooksby "Comparative Aspects in Virology" (Presidential Address).

British Coal Utilization Research Association (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Monsieur Raymond Cheradame: "From Coal to Coke" (Sixth Coal Science Lecture).

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. J. S. McPetrie: "Some Radio Aids for High-Speed Aircraft" (Chairman's Address).

Royal Institute of Chemistry (at King's College, Strand, London, W.C.2), at 6.30 p.m.—Dr. H. M. N. H. Irving: "Solvent Extraction in Inorganic Chemistry"

Radar Association (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 7.30 p.m.—Dr. Robin A. Smith: "Physics and Radar".

Thursday, October 17

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. J. M. Caw: "Control of Air Pressure as an Aid to Fight Mine Fires"; Mr. S. W. K. Morgan: "The Production of Zinc in a Blast Furnace".

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. J. S. Hughes and Mr. P. A. Griffin: "Silicones and the Treatment of Road and Building Materials".

Chemical Society (in the Large Chemistry Lecture Theatre, Imperial College of Science and Technology, South Kensington, London, S.W.7), at 7.30 p.m.—Prof. R. M. Barrer, F.R.S.: "Crystalline Ion Exchangers" (Tilden Lecture).

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Brigadier J. S. K. Boyd, O.B.E., F.R.S.: "Dysentery—Some Personal Experiences and Observations" (Presidential Address).

Friday, October 18

British Ornithologists' Union (in the Lecture Hall of the British Museum (Natural History), Cromwell Road, London, S.W.7), at 6 p.m.—Annual Scientific Meeting. Dr. N. Tinbergen: "Camouflage, Warning Colours, and Predators", illustrated by slides and a film.

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Sir George Nelson, Bt.: Presidential Address.

Saturday, October 19

Biochemical Society (in the Physiology Lecture Theatre, Guy's Hospital Medical School, London, S.E.1), at 2 p.m.—Scientific Papers.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Research Student, for research in internal combustion engineering or a related subject—The Registrar, King's College, Strand, London, W.C.2 (October 15).

Pathologist (with a diploma in clinical pathology or higher degree in pathology, and preferably additional experience in histopathology) in the Pathological Laboratories, Department of Public Health, New South Wales, Australia—The Agent General for New South Wales, 56 Strand, London, W.C.2 (October 18).

Assistant, Grade B (with a good honours degree, and preferably with teaching and/or research experience), to teach mathematics to B.Sc. general standard—The Principal, Norwood Technical College, Knight's Hill, London, S.E.27 (October 19).

Research Assistant in the Department of Physics, to take part in research, under the direction of the Head of the Department, leading to the development of solid-state image amplifiers—The Registrar, The University, Hull (October 19).

Veterinary Surgeon in the Experimental Pathology Department, for assistance with clinical and pathological work, with opportunities for research in experimental pathology—The Secretary, Institute of Animal Physiology, Babraham, Cambridge (October 19)

Assistant Librarian (chartered librarian, preferably F.L.A., with experience of technical college, university, or public library work) at the Nigerian College of Arts, Science and Technology—The Council for Overseas Colleges, 1 Woburn Square, London, W.C.1 (October 21).

Lecturer in Geography (with special reference to survey)—The Secretary of University Court, The University, Glasgow (October 21).

Lecturer in Mathematics; a Lecturer in Chemistry; and a Lecturer in Physics at the Nigerian College of Arts, Science and Technology—The Council for Overseas Colleges, 1 Woburn Square, London, W.C.1 (October 21)

Educational Psychologist (with a suitable degree and appropriate experience, including at least two years teaching)—The Director of Education, Shire Hall, Bedford (October 25).

Physicist-in-Charge of the Physics Department—The Group-Secretary, General Hospital, Nottingham (October 26).

Civil or Mechanical Engineers, Scientific Officer grade (with a first- or second-class honours degree in appropriate subjects) at the Hydraulics Research Station, (D.S.I.R.), Wallingford, Berks, for hydraulic research, including work on models—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. E.74/7A (October 29).

Assistant in the Department of Logic and Metaphysics in St. Salvator's College—Joint Clerk to the University Court, College Gate, St. Andrews (October 31)

Assistant Lecturer (with an honours degree) in Psychology at Canterbury University College, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, October 31).

Head (well-qualified graduate of a British university) of the Electrical Engineering Department—The Clerk to the Governing Body, Battersea College of Technology, London, S.W.11 (October 31).

Laboratory Technician in the Clinical Veterinary School, Kabete, Kenya (Makerere College—University College of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (October 31).

Reader (with high academic qualifications) in either Botany or Zoology—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (October 31).

Lecturer (with a good honours degree, and preferably industrial and/or research experience) in the Department of Mechanical Engineering—The Registrar, The University, Southampton (November 1).

Livestock Research Officer (Poultry) (with a university degree, preferably in veterinary, agricultural or pure science) at Seven Hills Poultry Experiment Station, New South Wales, Australia, to concentrate on genetical studies—The Agent-General for New South Wales, 56 Strand, London, W.C.2 (November 1).

Mathematician (with a first- or second-class honours degree in mathematics) at the Hydraulics Research Station, D.S.I.R., Wallingford, Berks, to lead a small section for theoretical studies in hydrodynamics and advise other sections of the Station which deal mainly with open-channel hydraulics and wave action—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.290/7A (November 2).

LECTURER IN ASTRONOMY—The Secretary of University Court, The University, Glasgow (November 4).

LECTURER (with an honours or higher degree in zoology and preferably some experience in university teaching) IN ZOOLOGY at the University of New England, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, November 8).

LECTURER, Grade I or Grade II (with a degree with high honours in engineering, physics or mathematics, and experience or an interest in the theoretical and experimental aspects of fluid mechanics), IN AERONAUTICAL ENGINEERING—The Registrar, The University, Bristol 8 (November 15).

CHEMIST (with a good honours degree in inorganic chemistry or equivalent) IN THE GEOLOGICAL SURVEY DEPARTMENT, Government of Tanganyika, for the analysis of rocks, minerals and ores, and to supervise junior staff in routine analytical work—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.105/8/09.

EXPERIMENTAL OFFICER or ASSISTANT EXPERIMENTAL OFFICER (with G.C.E. ("A" level) or H.N.C. or equivalent, some experience of physical chemical methods, and preferably a knowledge of metallurgical techniques), to investigate applications of radiotracers to problems in physical chemistry, with particular reference to the study of solids—Recruitment (936Z/34), Atomic Energy Research Establishment, Harwell, Didcot, Berks.

LABORATORY TECHNICIAN (PHYSIOLOGIST) (aged 24–40, possessing A.I.M.L.T. preferably in bacteriology, or equivalent, and a good practical knowledge of physiological laboratory technology), with the East African Veterinary Research Organization (East Africa High Commission)—The Crown Agents, 4 Millbank, London, S.W.1, quoting M.3/43369/NF.

PRINCIPAL OF THE UNIVERSITY COLLEGE OF WALES, Aberystwyth—The Registrar, University College of Wales, Aberystwyth.

SEED PRODUCTION OFFICER (with a recognized degree in agriculture, horticulture or an allied subject, and considerable postgraduate experience in seed production work, preferably with a private seed enterprise, and good administrative ability) in Cyprus, to administer the Seed Production Section of the Department of Agriculture and to supervise the production of cereal (wheat and barley), forage, lucerne, vetch, Egyptian clover, etc., vegetable and flower seeds for both local requirements and export—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD/63/17/03.

SENIOR EXPERIMENTAL OFFICER and EXPERIMENTAL OFFICER, for work relating to the criticality of fissile assemblies, fast reactor systems, and general neutron physics research including measurements with a pulsed particle accelerator; and an EXPERIMENTAL OFFICER or an ASSISTANT EXPERIMENTAL OFFICER, to work initially as a member of a team engaged on preliminary zero energy experiments leading to the commissioning of a research reactor, and later on experimental reactor physics—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref. 1582/34.

SENIOR LABORATORY TECHNICIAN FOR THE NUCLEAR SCIENCE LABORATORIES in the Department of Electrical Engineering and Physics—The Secretary, Borough Polytechnic, Borough Road, London, S.E.1.

SENIOR LECTURER (preferably with a higher degree in geology and teaching experience) IN GEOLOGY at the University College, Mandalay, Burma—The Ministry of Labour and National Service (E.9), 26–28 King Street, London, S.W.1, quoting A.12/BUR/TCS/218.

SENIOR LECTURER (preferably with industrial and/or research experience) IN THE DEPARTMENT OF MECHANICAL ENGINEERING—The Principal, Royal Technical College, Salford.

TECHNICIAN (preferably with a knowledge of chemistry and electrical apparatus) IN THE ZOOLOGY DEPARTMENT, to work in the Physiological Laboratory—The Registrar, The University, Nottingham.

(and up to 48″ long)

The internal diameter of Veridia (Regd) tubing has a tolerance of ± 0.01 mm (0.0004″) made in a range of sizes from 0.04 mm to 34.50 mm. Much of it is made in lengths of 48″. It is used extensively in the construction of industrial and laboratory measuring devices as well as for making accurate jets and for extruding and spinning plastic materials into threads of controlled diameter. Further information, including range of bore diameters and lengths available, is contained in Veridia leaflet OS14. Please write for free copy to

THE
MATHEMATICAL
THEORY OF
EPIDEMICS

This monograph presents a full and generalized mathematical treatment of the phenomena involved in the spread of epidemics. The author is one of the leading British authorities, and not only has he brought together many interesting and valuable results achieved elsewhere, but includes a considerable amount of unpublished original material. The main emphasis is placed upon the biometrical and epidemiological aspects rather than the purely mathematical, and the work will be found relevant to many of the problems encountered by Public Health Authorities, medical officers, biologists, and clinical research workers in the investigation and control of the diseases which claim so great a toll of human life and happiness.

MUSEUMS AND ART GALLERIES IN BRITAIN

FOR years, and at least since 1939, the Museums Association, representing the museums and art galleries of Great Britain and Northern Ireland, has been urging H.M. Government to take active steps to safeguard such part of our national heritage as is housed in the museums of the country. Perhaps a brief résumé of the past history of this problem will give a clearer picture of the present position and the apparent reluctance of the Government to help in the matter.

It was as far back as 1922 that, at the annual conference of the Museums Association, a resolution was passed urging the Prime Minister to appoint a Royal Commission to investigate and report upon the work of the museums of the United Kingdom. Unfortunately, the death of the fourth Lord Sudeley stopped any progress in this direction, and the Association sought and obtained the good offices and sympathetic interest of the Carnegie United Kingdom Trust. This indeed was a landmark in the history of the museum movement in Britain, for since 1925 to the present day the Trustees and their officers have not ceased to make substantial grants for specific schemes and to explore the possibilities of some permanent form of assistance from the State. In accordance with their general practice, the Trustees commissioned a general report on the museums of the United Kingdom and this was prepared by Sir Henry Miers and Mr. (now Sir) Frank Markham. The report, published in 1928, advocated, among other matters, financial assistance from national funds, government departments, county authorities or other external sources.

Then again, during the presidencies of Sir Mortimer Wheeler and Lord Bledisloe in 1938 and 1939, the Museums Association took active steps to interest the Government in the problem. Lord de la Warr, then President of the Board of Education, promised to set up a Royal Commission on the provincial museum service, but the Second World War intervened.

After the War, the matter was again raised, numerous discussions took place and the most realistic result was the proposal made by the Chancellor of the Exchequer to allocate £250,000 annually for museum purposes. But the economic crisis of 1949 intervened, and the grant did not materialize.

In 1955 the Association renewed its arguments and appointed an influential Joint Committee consisting of representatives of the Carnegie United Kingdom Trust, the Arts Council and itself, to which was later added representatives from the National Institute of Adult Education. The memorandum from this Committee was presented to the Chancellor of the Exchequer on November 16, 1955. The document stressed the rapid growth of the public conscience regarding the value of museums as cultural and educational forces and documented the plight of many of the museums in Britain, especially those in the care of trustees and societies, some of the latter being hard pressed to the point of extinction. It was stated, with convincing examples, that the cost of maintenance, of both the collections and buildings, together with increased salaries and wages of staff, places an increasingly heavy burden on greatly depleted funds. In many cases the struggle cannot continue much longer, and already valuable objects are in dire need of conservation and will be lost to the national heritage unless immediate steps are taken.

The Joint Committee advocated the appointment of a Royal Commission "to inquire fully into the whole question of the financing and administration of all museums and art galleries in the United Kingdom with especial reference to those situated in the provinces". In view, however, of possible delay with a Royal Commission, the Committee urged as a first-aid measure that the Government should make available immediately a fund to help the most necessitous cases. It was recommended that the fund should certainly be not less than £50,000, and to this the Carnegie United Kingdom Trust generously and spontaneously promised a further £25,000. It was further recommended that the fund might be administered simply and effectively by the methods so successfully initiated and maintained by the Joint Committee of the Museums Association and the Carnegie United Kingdom Trust. This Committee could be enlarged by representatives of the Government and any fund allocated with the minimum of expense and without the setting-up of a new organization.

High hopes were entertained that this new approach to the Government would yield positive results; but unfortunately, and just about twelve months after the memorandum was submitted, a negative reply was received to both requests. The Museums Association was told that the problem is essentially a local matter, and that museums and art galleries must look to local authorities for the financial assistance they require; and in denying a Royal Commission the Government stated that the facts are already well known. But despite the reply of the Government, the urgent need for financial assistance exists and several museums must close unless some help is forthcoming. Examples abound and among these may be mentioned the Holburne Museum at Bath and the County Museum in Truro, Cornwall. With excessive economies and existing only by the enthusiasm and self-sacrifice of the trustees and curators, both these institutions have an accumulated annual deficit, and the need for urgent consideration of their problem is self-evident. It was only recently that the trustees of the Bowes Museum at Barnard Castle, where the art treasures have an international reputation, named an actual date for closure.

Fortunately, the Durham County Council came to the rescue and the financial stability of the Museum is assured.

That is the present position of the problem and in spite of the setback produced by the negative attitude of the Government, the Museums Association is discussing the matter actively and bringing forward new proposals. The matter was fully ventilated at a session in the recent annual conference of the Association at Bristol, when under the chairmanship of Sir Mortimer Wheeler the idea of regionalization in museums was discussed. As a matter of broad principle, it is felt that the problem is a national responsibility and not essentially a local matter. The Association stands firm on this, and believes that there should be a central museum authority or commission with local organizations which perhaps could be regarded as regional museums boards.

Although the Government considers that it is fully aware of the facts of the situation, the Joint Committee feels that they are not by any means fully known. It therefore proposes to undertake a complete survey of the museums and art galleries of Britain. Such a survey would be concerned with the geographical distribution of museums and their relationships—chiefly financial—to local and county council authorities. But such a comprehensive survey would naturally be an expensive project, and at present consideration is being given to a pilot scheme probably in the south-west of England. Based on the results of the survey, it should be possible to formulate clearly the function and policy of one of the suggested regional museums boards and to make recommendations regarding its constitution and headquarters.

Even at the present time, the National Museum of Wales carries out some of the functions of the proposed regional museums boards. All museums in Wales and Monmouthshire, providing they attain certain standards, are affiliated to the parent museum at Cardiff. This idea is different from the regional federations in England, where the individual units are loosely held together with no one museum acting as a focus or providing the initiative for any scheme.

In the event of these regional museums boards being appointed, it is felt that the Government would be provided with authoritative bodies through which grants could be made to museums. The reluctance of the Government to make grants to individual museums would thus be overcome by a system of regionalization whereby boards rather than separate museums would be the recipients. It is also visualized that county councils and other local authorities would contribute towards such boards.

But even with such a regional scheme which has been well considered by the Joint Committee, the way still remains open for other means of approach towards the solution of the problem. It may be that the Standing Commission which is appointed by the Treasury could undertake the task and lessen the financial burden of the local museum, and especially trustee or local society institutions. In the terms of reference of this body, provision is made for consideration of the co-ordination of the work of the national museums with those in the provinces. Unfortunately, the Standing Committee has no funds at its disposal, and thus in the past has had no real impact on the museum problem. If, however, its constitution were strengthened and certain monies were available as grants, there is little doubt that such an organization would go far to meet the present unhappy position.

Recently, there has been an undoubted growth of the public conscience concerning the value of museums and art galleries. They are now part and parcel of the normal life of the community, and not something set apart for a few specialists. Museums and art galleries are a definite integral part of the educational and recreational services, and as such should be encouraged and maintained by the Government and not left to the dwindling resources of societies or trustees.

PHYSICS OF THE SOLID STATE

Solid State Physics

Advances in Research and Applications. Edited by Frederick Seitz and David Turnbull. Vol. 1, Pp. xii+469. (1955.) 10 dollars. Vol. 3. Pp. xiv+588. (1956.) 12 dollars.
(New York: Academic Press, Inc.; London: Academic Books, Ltd.)

THE authors of "Solid State Physics" deserve our best thanks—as do the editors, who are continuing to extract review articles of the highest standard covering important branches of physics. Notice of Vol. 2 appeared in *Nature*, 178, 1139 (1956). Two-thirds of Vol. 1 provides, in effect, a modern handbook on electrons in metals. First there is an excellent expository article by J. R. Reitz, "Methods of the One-electron Theory of Solids", which takes us gently through the basic groundwork and emerges with a detailed and up-to-date account of the 'tight binding' approach (linear combination of atomic orbitals) and the 'cell' method. In addition the author considers a number of more modern developments including the use of orthogonalized plane waves and variational methods. Next comes a remarkable qualitative account of metallic cohesion by E. P. Wigner and F. Seitz. Appropriately enough, the authors base their discussion on the Wigner–Seitz treatment of the cell method; they are specifically concerned with 'difficult' metals—not merely the alkalis.

The next article, "The Quantum Defect Method", by F. S. Ham, is more technical: it describes how, in suitable cases, numerical treatment of the ion-core region in band calculations can be replaced by a knowledge of the atomic spectrum. Many of the ideas here are due to T. S. Kuhn, J. H. Van Vleck and H. Brooks. The last 'metal' article—and that owing least to the 1930's—is an account of electron interaction in metals by D. Pines. It is, of course, based on the collective electron theories due largely to Pines and D. Bohm. This article is very full and readable; it includes some account of relevant experimental data (band-widths, magnetic susceptibilities, characteristic energy losses) and also a section on lattice-electron interaction.

There are two remaining articles in Vol. 1: an account by H. Y. Fan of the properties of germanium and silicon which, although comprehensive, will be found comprehensible by physicists who are not well informed on the subject of semi-conductors; finally, an article on order–disorder transitions in alloys by T. Muto and Y. Takagi which includes a specially valuable discussion of the influence of ordering on electrical, magnetic and mechanical properties.

The subject of order–disorder transitions in alloys is given a more original treatment by L. Guttman in Vol. 3. He makes a serious attempt to judge the Ising model in the light of experiments; the discussion is fascinating and—of course—inconclusive.

There are two stimulating reviews of new subjects in Vol. 3: an account of the unusual semi-conducting properties of Group III–Group V 'intermetallic' compounds by H. Welker and H. Weiss (the electron mobility in InSb is so high that it is possible to use the Hall effect in a small, sensitive device for measuring magnetic fields); and a more theoretical and very elegant article on the continuum theory of lattice defects by J. D. Eshelby.

The masterly survey by C. Kittel and J. K. Galt, "Ferromagnetic Domain Theory", improves and brings up to date a well-known article, now seven years old, by the first author. D. Turnbull writes with his customary authority on the kinetics of phase transitions but is less than happy in other parts of an article entitled "Phase Changes". The remaining contribution to Vol. 3 is a long and turgid, but no doubt expert, treatment of imperfections in crystals by F. A. Kroger and H. J. Vink. It is concerned with their concentrations and uses the methods of physical chemistry.

It is now clear why the quality of "Reviews of Modern Physics" has declined during the past few years: some at least of its potential contributors are giving of their best to collections of the type under notice.
R. O. DAVIES

EFFECTS OF IONIZING RADIATION

Proceedings of the International Conference on the Peaceful Uses of Atomic Energy

Held in Geneva, 8 August–20 August, 1955. Vol. 7: Nuclear Chemistry and Effects of Irradiation. Pp. x+691. 10 dollars; 70*s*.; 43 Swiss francs. Vol. 11: Biological Effects of Radiation. Pp. viii+402. 8 dollars; 57*s*.; 34 Swiss francs. (New York: United Nations; London: H.M. Stationery Office, 1956.)

VOL. 11 of the Proceedings of the Geneva Conference should be familiar to all those engaged on nuclear research projects where the danger of exposure to radiation is not negligible. In detail it treats with many subjects, in terms not always readily understood by physicists and the like, but there is a sufficient number of general articles extremely well written which will repay careful reading by the non-specialist. Those of us who can remember the conditions of nuclear experimentation, even before the Second World War, in the Cavendish Laboratory will recognize the great improvement which has taken place in our knowledge of radiation hazards and in techniques for their assessment.

Fortunately for the rest of Nature, if we take sufficient care radiobiologically to look after mankind, says Dr. Loutit, Nature will take care of itself, because sensitivity to ionizing radiations is well correlated with the degree of evolutionary complexity (I recall that in another volume the lethal radiation dose for humans was given as 500 röntgen units, for insects 50,000, and for trichinosis 1,000,000). There has been so much experience gained from X-ray and radium damage to human beings that scientists enter the nuclear age reasonably well informed of the general hazards to be faced and, in addition, several Japanese papers give accounts of the first victims of fission.

Apart from radioactive fall-out and war, scientists are only likely to encounter by accident higher doses of radiation than 'permissible', and more evidence is needed about the effects of, and treatment for, doses near to or above 'permissible' levels of radiation. At appreciably lower radiation-levels, profound questions are raised that might not be answered for a long time to come, such as whether radiation, which we know can cause changes in genes, is likely to cause mutations which determine the change from normal to malignant potentiality. It seems that we know virtually nothing about the effects of radiation on the genetics of man, and can only guess what is the dose necessary to double the spontaneous mutation-rate of some genes. An American writer suggests that we might some time arrive at a 'permissible' dose determined by genetic considerations and not merely a dose based on physical injury. As a general precautionary measure the radiation-level of the Thames drinking-water was lowered by a factor of 100, but ultimate figures have not yet been selected, for there is no answer to the question: At what value does the dose-rate assume importance? In spite of these long-term uncertainties, E. Rock Carling's assessment is that in nuclear research establishments where attention is correctly given to radiation dose symmetry, average levels of exposure are far below those recommended as permissible.

L. H. Gray presents a most interesting review of what is known in detail about the biological damage caused by ionizing radiations. At low doses the proportion of cells affected by single ionizing particles increases linearly with the dose. There is no threshold below which the radiation is without effect, and structural damage to chromosomes can be directly observed in strict proportion to the dose, but different cells show differences in sensitivity to radiation. They may all suffer damage, but the injuries in some cells are not manifest. Injury is often made manifest only at the time of cell division, and in the case of seeds this might be years after the date of irradiation. In addition to the physical act of ionization there are the chemical changes which occur even in water, such as the formation of hydroxyl, atomic hydrogen and hydrogen peroxide radicals, and Gray concludes that there are good grounds for believing that the radicals revealed by studies in radiation chemistry play an important part in the development of some forms of radiobiological damage. It is encouraging to turn to later papers by Hollaender and Stapleton, dealing with chemical treatment to prevent or to reduce radiation damage. Certain reducing chemicals will produce effects similar to those obtained when oxygen is absent: some have been found to reduce by a factor of six the damage caused by a given dose of radiation if these chemicals are present at the time of irradiation, and the properties of radiation protectors suitable for use on a large clinical scale can now, at least, be defined, and work on these seems to be extensive.

The effects of radiation on water is the subject of several papers in Vol. 7, the emphasis here being on water used at ordinary or high pressures, and at low or high temperatures, for the cooling of power reactors, and also on water intimately associated with the fission process as it is in the aqueous homogeneous reactors. Gamma-rays absorbed in water produce mainly the hydrogen and hydroxyl radicals, whereas heavy particle radiation produces molecular hydrogen and hydrogen peroxide. In the presence of intense gamma- and neutron-radiation, as in the Chalk River and other heavy-water reactors, the formation of the hydrogen and hydroxyl radicals is so great that two reverse reactions occur in which the hydrogen ion unites with the hydrogen peroxide molecule and the hydroxyl ion unites with the hydrogen molecule, with the net result that no decomposition of water is observed. This recombination reaction is of comparatively recent discovery, for it was not suspected when water-moderated reactors were first designed. If radicals are removed by some reactive substance, the reaction balance is altered and rapid decomposition of water sets in. In high-pressure water-moderated reactors, control of dissolved gases and acidity of the water are very important, for mass transfer of corrosion products due to temperature or electro-potential gradients can become serious. All the contributors state that the various mechanisms discovered are far from being understood, and a great amount of work yet remains to be done.

A few papers deal with the effect of radiations on liquids other than water, and, in particular, there is the American account of the study of the aromatic hydrocarbons, especially the di- and ter-phenyls under irradiation. These materials are stable up to temperatures of the order of 400° C., but in the presence of radiation form compounds of both higher and lower molecular weight and evolve hydrogen, but in this respect the ter-phenyls show less decomposition than any other substance studied. The conclusion is reached that the stability of these materials is sufficient to justify their use as coolants and moderators in high-temperature reactors operating in the 400° C. range.

Many papers deal with the effect of radiation on solids, primarily on uranium, on moderators such as graphite and beryllium, and on other structural materials used in reactors. The subject is of enormous size and importance and continues to have almost a dominating role in the reactor research and development since Geneva. The damage done to uranium during its life in a reactor is a combination of two phenomena: a change of shape caused by local expansion of the lattice around the fission fragment track, followed by plastic flow on cooling; and an increase in volume due to the accumulation of gaseous fission products, but the damage is especially troublesome because uranium has most unusual crystalline properties. Thorium suffers far less damage but, of course, we are not yet ready to use thorium as a fuel on a large scale. The improvements made to uranium to reduce damage are described in an American paper. Fortunately, the graphite used in reactors is a conglomeration of crystallites, so that radiation damage is not markedly anisotropic: radiation damage to a flake of natural graphite causes expansion one order of magnitude higher than that to artificial conglomerate of graphite. One disturbing report states that damage to graphite in the M.T.R. reactor cannot be correlated with damage to graphite taken from the Hanford reactors. There is very little written about the change of properties of other structural materials used in reactors, but the Russians and Americans who use stainless steel in water- and sodium-cooled reactors give brief accounts.

Vol. 7 deals also with the fission process, and the chemistry of the fission-products and the transuranic elements up to curium. It was a pleasure to see Dr. Otto Hahn in the chair at the session on fission process; whereas he discovered barium in the neutron-bombarded uranium in 1938, to-day we know that thirty-six different elements are found and, in all, 300 different isotopes of these elements occur due to fission. He spoke of the safety inherent in the small sources he used, and the papers delivered in that session report the extreme complexity of the modern 'hot' laboratory for handling the fission products.

T. E. ALLIBONE

THE MECHANICS OF THE MIND

Schools of Psychoanalytic Thought

By Dr. Ruth L. Munroe. Pp. xvi + 670. (London: Hutchinson Medical Publications, 1957.) 42*s*. net.

IT is a favourite jibe of those who dislike psychoanalysis that it is not a science (or even the beginnings of a science) but another form of religion. Such people disregard the fact that the analyst, remaining almost constantly silent, observes the patient and his thoughts for an hour a day over a period of months or years. Psychoanalysis is based on these observations, and the deductions made from them regarding the deeper levels of the mind. Religion is static except for accretions due to absorbing minor beliefs, but psychoanalysis is daily growing and developing.

This book, which is an excellent one, describes the paths along which the work of Freud is developing. Some of his original views have been modified, and a great deal has been added to his systems.

Dr. Ruth Munroe is a professor of psychology who, moreover, is married to an American psychoanalyst who has contributed a great deal of work on his subject, and lives in an environment with many analytical contacts.

The book is divided into three parts. The first is called "An Overview" and is more or less introductory. The views of the various analysts considered are placed under headings: the terms of the organism, the terms of the milieu, the genetic process, dynamics of the functioning personality, pathology and treatment. This allows the author to compare and criticize the different ideas. The second part of the book considers, from this point of view, the systems of Freud and those who have not deviated too far from him still to retain the term 'Freudians'.

The third part of the book is devoted to Adler, Horney, Fromm and Sullivan. Their investigations and conclusions are put through the same sieve. The fourth section is devoted to Jung and Rank. The last part summarizes the matter which has gone before and collates the whole into a pattern.

It will be seen that such a scheme is a very ambitious one, and it says much for the author's knowledge, industry, ability and broad sympathies that she has made it not only knowledgeable but readable. She is even capable of reading Jung (who infuriates most analysts) and making his rubrics into something intelligible, although often not acceptable in his terms to those who believe in a different system.

The reader might ask impatiently, what have they found out ? What is all this psychoanalytical investigation about ? Unfortunately without taking up too much space it is difficult to give even an outline. Briefly, the most important discoveries concern the beginnings of thought in the tiny baby. A shaft is being driven into the obscurities of infantile conceptions towards understanding not only how a baby thinks but also why he does so. This gives us clues to the structure and development of the personality. Much of this work is based on the theories of Melanie Klein and her school in England. The work of the other researchers throws a great deal of light on how the person reacts once his personality has matured, and why he behaves as he does. For example, Fromm tries "to relate specific personality types to specific social-economic patterns" and Sullivan shows the importance of the pursuit towards security and so on. The views of others are too well known for comment here.

Anyone interested in psychoanalysis should read this book, which gives a wealth of valuable information only obtainable otherwise by summarizing a large number of original works. Its only fault is that at times it is a little repetitive and verbose, but it is usually extremely clear.

I remember when I was a young man discussing the work of Rutherford and Soddy with a very conservative physicist. The physicist said: "It's all very interesting, but really of no practical importance. We shall never split the atom". Psychoanalysis may be regarded, perhaps, as in a much more primitive state than physics at that time, but it still gives a similar hope for the future. The book is well bound, and excellently printed on non-shiny paper The index and bibliography are adequate.

CLIFFORD ALLEN

CHROMATOGRAPHY—THEORY AND PRACTICE

Chromatography

A Review of Principles and Applications. By Prof. Edgar Lederer and Michael Lederer. Second, completely revised and enlarged edition. Pp. xx+711. (Amsterdam: Elsevier Publishing Company; London: Cleaver-Hume Press, Ltd.; Princeton, N.J.: D. Van Nostrand Company, Inc., 1957.) 72s.

Fundamentals of Chromatography

By Prof. Harold Gomes Cassidy. (Technique of Organic Chemistry, Vol. 10.) Pp. xvii+447. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1957.) 9.75 dollars.

THE first edition of "Chromatography" by Prof. E. and Dr. M. Lederer was widely accepted as the standard general work on the subject, but the growth of chromatography has continued so rapidly that, after only four years, the authors have considered it necessary to prepare a second edition, which is a complete revision and contains about half as many pages, figures, tables again, and more than 3,700 references—about twice the original number. Some obsolete earlier work has been deleted; recent developments which previously could only be briefly mentioned, such as gradient elution, radioactive tracer techniques, ion-exchange celluloses for protein chromatography and specific adsorbents, now receive fuller treatment. Gas–liquid chromatography has a chapter to itself which is a short introduction to the subject and an appendix gives the references in this field up to the time of going to press. Many of the original tables are considerably enlarged to incorporate data published in the past few years. Those giving R_F values and solvent systems for paper chromatography of the metals are typical of the thoroughness with which the authors have reviewed applications. Presentation follows a pattern similar to that of the first edition and the result is a very attractive volume. It is perhaps inevitable, in a review of such a vast field, that some topics, such as the paper chromatography of the barbiturates, have been overlooked or treated too briefly, but such examples are remarkably few. It can be confidently predicted that this monograph will be as widely welcomed as its predecessor.

Prof. Cassidy treats the subject from rather a different angle. Although he and the Lederers overlap to a certain extent, their books may be regarded as complementary, since aspects dealt with less fully in one are treated more fully in the other. Thus, the general theory of chromatography and the principles underlying the various types of chromatographic separation, including gas chromatography, are discussed at length by Prof. Cassidy. He also goes very fully into practical aspects and deals in great detail with the use and properties of stationary and mobile phases used in all the forms of chromatography. Guidance to choice of conditions for carrying out chromatograms is among a number of other topics which are discussed fully and a valuable appendix gives sources of equipment.

There are some omissions and inadequacies. In the past few years there have been important developments in the chromatography of proteins, yet this subject is not treated as fully as it deserves. Ion exchange celluloses, for example, are not mentioned, neither is salting-out adsorption nor the use of tricalcium phosphate. There is little about the principles underlying metal separations on ion exchange resins employing complexing agents. On the other hand, too much space is devoted to electron exchange polymers and to foam fractionation. Both methods have so far been little used for separations, and it seems to be stretching definitions rather far to include the second technique as a chromatographic process. However, the chief fault of Prof. Cassidy's book lies with presentation rather than content. A tendency towards garrulity sometimes obscures the points being discussed, as, for example, on p. 198, and there are too many long passages of practically unbroken text which are rather trying to the eye. Added to which the occasional and irritating use of jargon (for example, "overly retarded", p. 377; "this is the time analogue of overloading", p. 202; "derive patterns of procedure", p. 386) does not make for easy reading. Nevertheless, in spite of these faults, Prof. Cassidy's book is a real contribution to the literature of chromatography since it goes a long way towards improving our understanding of the complex processes taking place in the many varieties of chromatogram.

R. CONSDEN

The Yearbook of the Universities of the Commonwealth, 1957

Pp. lx+2067. (London: Association of Universities of the British Commonwealth, 1957.) 73s. 6d.

THE aim of the Association of Universities of the British Commonwealth, as the authority responsible for the production of this useful handbook, is that of providing basic information on all the universities and university colleges of the Commonwealth, their activities and their staffs, in a single volume for ease of reference. The present rate of growth, both in number and in size, of the universities in Great Britain, and indeed throughout the Commonwealth, has, however, produced a concurrent expansion in the "Yearbook", which now has more than two thousand pages, compared with less than six hundred in 1921. It has become apparent that the framework of contents and format of the volume could with advantage be altered, the better to accommodate the large increase in information bound between its covers. It is stated in the preface that plans are accordingly now being made for the next issue to appear in a completely revised form, with a different shape and appearance.

Meanwhile, the contents of the present issue have been revised up to May 1956, and in some cases to a rather later date. The University of Leicester still appears among the university colleges, Exeter has taken its place among the English universities, and the entry for the new University of Khartoum—although the Sudan has now no formal connexion with the Commonwealth—is retained in an appendix which also includes the universities of the Republic of Ireland having historical associations with British institutions. Two new Indian universities appear for the first time—Thackersey Women's University of Bombay and Sri Venkateswara University, Tirupati—and a detailed entry is included for the University College of Rhodesia and Nyasaland.

The "Yearbook" remains a source of reference indispensable to all who are concerned with academic, scientific and editorial affairs.

Chemistry in the Service of Man

By Prof. Alexander Findlay. Eighth edition. Pp. xx+326+36 plates. (London and New York: Longmans, Green and Co., Ltd., 1957.) 25s. net.

THIS classic was first published in 1916. For the new edition the publishers have used a larger format and have increased the number of illustrations. The 390 pages, each 4¾ in. × 6¾ in., of the 1947 edition now become 326 pages, each 5¾ in. × 8¾ in., but in addition there are now twenty-seven line drawings and thirty-six half-tone plates.

Responsive to the shift of emphasis consequent upon the synthesis of many new materials of economic and industrial worth, Prof. A. Findlay has rearranged and rewritten much of the book. He has deleted the old Chapter 2 on atomic structure, and has incorporated the matter in a new Chapter 17 dealing with radioactivity, tracer elements, nuclear chemistry and the right use of nuclear energy. The two chapters on synthetical chemistry, formerly numbered 15 and 16, have undergone much revision and now appear under these new chapter numbers and titles: Chapter 13, "Dyes, Perfumes, Drugs and Insecticides", and Chapter 14, "Artificial Fibres and Plastics". Materials and phenomena in the public eye, such as silicones, 'Terylene' and adsorption, all receive due attention. Forty years ago the publication of this book caused many science teachers to see chemistry in a new light and helped them to promote a better presentation of their subject. Brightened with the new illustrations and everywhere brought up to date, the new edition should delight and inspire a new generation.

Polyesters and their Applications

By the Bjorksten Research Laboratories, Inc. Pp. vii+618. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1956.) 80s. net.

THIS book reviews the period to June 1954 with a supplement to early 1956. Its principal value is for reference, since more than half consists of an annotated bibliography. Polyesters are defined as the polycondensation products of dicarboxylic acids and dihydric alcohols, thereby excluding polymers with side-chain ester linkages. The introductory theoretical chapter is unsatisfying, brief and in places inaccurate. For example, the molecular weight distribution of the products of a polycondensation is incorrectly stated, and it is surprising to see polystyrene described as a highly polar molecule.

Unsaturated, fibre-forming saturated and di-isocyanate modified polyesters are treated in the next three sections. In places excessive detail is given, as in lists of potential curing agents, whereas the polyurethanes receive only eight pages. Reinforcing fibres are interestingly discussed; the expectation of a good treatment of the sizing and finishing of glass fibres was fulfilled. To regard fibres merely as improving the strength of a resin seems an incorrect emphasis, and a discussion of fibre orientation is lacking. The chemical reactivity of glass fibres is greater than might be inferred by the reader of this section.

The reproduction of data sheets and the discussion of specifications other than those of the well-known American Society for Testing Materials and Federal series remind British readers of the source and principal users of this book. A brief chapter on health hazards should fulfil a useful purpose.

E. W. RUSSELL

Soil Physics

By Dr. L. D. Baver. Third edition. Pp. xvii+489. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1956.) 62s. net.

"SOIL PHYSICS" was originally designed as a text-book for graduate students in agronomy, but over the years it has become something more. Advisory and research workers, including professional physicists, have used it as a standard reference book, and, perhaps somewhat unfairly, have criticized it because the treatment of many topics was not thorough enough to meet their specialized needs. The new edition will silence some of, but not all, this criticism, for it is more nearly a book about physics than either of the first two. It has all their virtues in an enhanced form, with new chapters on irrigation and drainage, and new material on several aspects of soil structure and stability. The outlook remains essentially practical, the descriptive sections are well written, there are plenty of tables and diagrams of field observations, and as all this is supported by an excellent bibliography, Baver's "Soil Physics" will have no difficulty in holding its place as the best available general guide to the physics and physical chemistry of the soil.

ROYAL AIRCRAFT ESTABLISHMENT, BEDFORD

By L. H. G. STERNE

Chief Superintendent

A NEW aeronautical laboratory was formally opened at Bedford by Mr. Aubrey Jones, the Minister of Supply, on June 27. This laboratory, which is part of the Royal Aircraft Establishment, was planned during the closing years of the Second World War when it was evident that there was inadequate space in the Establishment's Farnborough laboratory, either for the runways required for flight research on supersonic aircraft, or for the considerable variety of wind tunnels which alone can provide the aerodynamic knowledge essential to the successful design of aircraft and missiles.

By mid-1946 plans for both the wind-tunnel site and the airfield at Bedford were well advanced, and at the end of 1949 most of the roadways had been completed and work had begun on a 3 ft. × 3 ft. supersonic wind tunnel. Three years later this tunnel was in full operation, assisting the aircraft industry in testing models of new designs, and a good deal of work had been done on the construction of the main runway. Further tunnels have since been constructed, notably the recently completed 8 ft. × 8 ft. —the most powerful and complex wind tunnel in Britain. The Naval Air Department and the Flight Division of the Aerodynamics Department were transferred from Farnborough to Bedford Airfield in 1955 and the Blind Landing Experimental Unit joined them from Martlesham Heath this year.

Wind tunnels. The wind tunnels at Bedford are intended to be complementary to those at Farnborough and the work done in them is part of an integrated programme of aerodynamic research pursued by the Royal Aircraft Establishment as a whole. When the 4 ft. × 3 ft. tunnel (now under construction) is completed, the Establishment will be equipped with an extremely valuable range of wind tunnels in which models of useful size can be tested from low speeds, through the speed of sound, up to a Mach number of 5.

Two main kinds of work are done: first, tests are made on models of actual aircraft or missiles, either to measure their characteristics before they have flown, or to investigate the cause and cure of troubles which have been encountered in flight; and, secondly, tests are made on idealized shapes, either to check theoretical calculations, or to obtain basic aerodynamic information to assist future design.

Except in the vertical spinning tunnel, the basic method of testing is the same in all cases: the model is supported in the airstream and measurements are made of the forces acting on the model, or of the pressure and velocity distribution on the model surface or in its wake. In order to save time, both in the testing and the subsequent analysis of the results, arrangements are provided for recording all measurements automatically: by curve plotters to provide a visible record immediately, and on punched cards for later reduction by an electronic computer. In addition to these measurements, various methods of flow visualization are used; for example, oil films, smoke trails, and optical schlieren equipment. All the tunnels at Bedford are of the continuous-flow type.

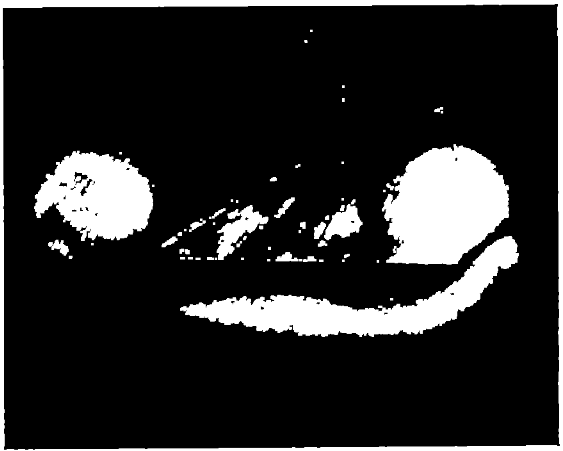

Fig 1 Photograph of smoke trails taken in the 13 ft. × 9 ft. wind tunnel showing vortex pattern behind a delta-shaped wing

The 13 ft. × 9 ft. subsonic wind tunnel has a speed range from zero to 300 ft./sec. and is mainly used to explore the low-speed (including take-off and landing) characteristics of aircraft and aerodynamic shapes designed for good performance at transonic and supersonic speeds (see Fig. 1).

The tunnel circuit is constructed mainly in concrete, and the air is circulated by a single-stage fan, 30 ft. in diameter, driven by a 1,500 h.p. direct-current electric motor, with a Ward–Leonard control. To ensure an exceptionally high degree of uniformity of flow in the working section, there is a large settling chamber giving a contraction ratio of 16 : 1, fitted with four fine-gauze screens. Auxiliary compressor and evacuator plant is provided for tests involving boundary-layer control by sucking or blowing.

The 3 ft. × 3 ft. supersonic wind tunnel can be operated at any supersonic speed up to a Mach number of 2, variation of speed being effected by the use of interchangeable shaped-blocks on one of the walls of the working section. An alternative working section of the ventilated type is also available, enabling tests to be made at transonic speeds (see Fig. 2). This tunnel can be operated at any stagnation pressure between 0·1 and 2 atmospheres absolute, and is powered by electric motors totalling 16,000 h.p. driving two centrifugal compressors in series.

The 8 ft. × 8 ft. supersonic wind tunnel (Fig. 3) is the largest of its kind in Britain. It can be operated at any Mach number from zero to 2·8 (excluding the transonic range) and the stagnation pressure can be adjusted to any value in the range 0·1–4 atmospheres absolute. It is driven by electric motors totalling 80,000 h.p., and the electricity supply can be obtained

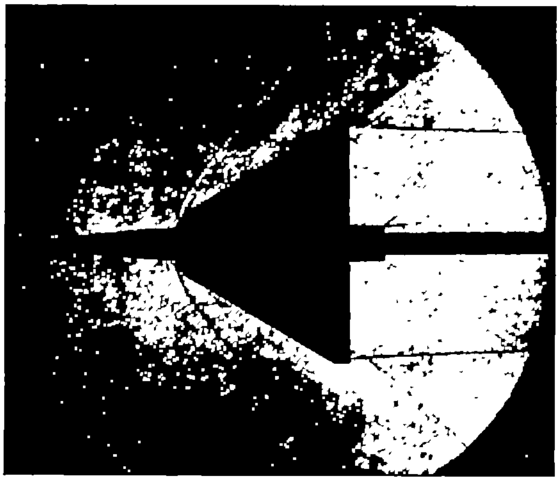

Fig. 2. Shock-wave pattern; picture taken in 3 ft. × 3 ft. supersonic wind tunnel

either from the National Grid or from a gas-turbine generating station on the site, the latter source being limited to about 50,000 h.p. A feature of this tunnel is the adjustable nozzle (for varying the Mach number in the test section), consisting of two flexible steel plates 62 ft. long and 1 in. thick, bent to the required shape by hydraulically operated jacks which are set to a high degree of accuracy by an elaborate control system. The supersonic diffuser following the working section is also made adjustable, to reduce the power required to drive the tunnel.

The 4 ft. × 3 ft. supersonic wind tunnel, which is still under construction, will have a Mach number range from 2·5–5, and will work at pressures up to 15 atmospheres absolute. Its power will be 88,000 h.p., and, as in the case of the 8 ft. × 8 ft. tunnel, the electricity supply can be taken either from the National Grid or from the gas-turbine station. Flexible steel walls will be used for providing variation of speed in the working section.

A special feature of this tunnel is that provision is being made for operating at stagnation temperatures up to 150° C., in order to avoid partial liquefaction of the air in the working section at the higher Mach numbers.

The vertical spinning tunnel is used primarily to observe the behaviour of free models in spinning flight, and particularly to investigate methods of recovery from a spin. The working section is 15 ft. in diameter, and the air flow, which is directed upwards, is under the direct control of the operator, so that the model remains at the same height and can be kept under observation all the time.

Pressure in the tunnel can be raised to 4 atmospheres absolute to reduce scale effect, and the maximum air speed is 90 ft./sec. at full pressure and 140 ft./sec. at atmospheric pressure. The air is circulated by a variable-pitch fan, driven by a synchronous motor of a nominal 1,500 h.p. with an overload capacity of 3,000 h.p.

Airfield. Bedford Airfield is surrounded by open countryside, affording excellent approaches to all runways, and is especially suitable for research on high-speed aircraft. The main runway is one of the longest and widest in the country (10,500 ft. × 300 ft.). There are two other normal-flying runways, and, in addition, the Naval runway fitted with carrier-type arrester gears for research into the recovery of naval aircraft. The control tower is equipped with the latest types of radar equipment giving a coverage of 100 miles with full talk-down facilities of the latest type. There is a two-channel, multi-frequency, cathode-ray direction finder, and

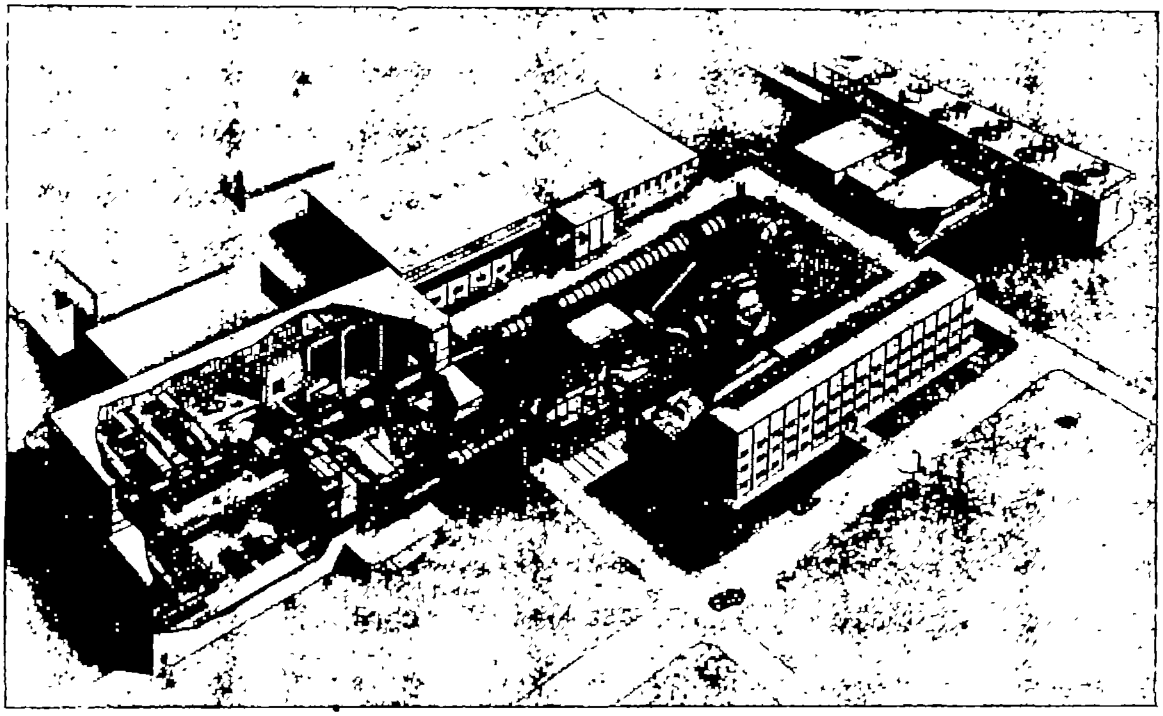

Fig. 3. General view of the 8 ft. × 8 ft. supersonic wind tunnel at Bedford

the airfield is an integral part of the Establishment's very-high-frequency fixer network, with which it is possible to cover most of the country.

Aerodynamic flight research. The underlying aim of the work of the Flight Division of the Aerodynamics Department is to further the improvements of future aircraft, either directly, by determining the value of aerodynamic innovations in design, or indirectly, by the introduction of new or improved test techniques or means of recording and processing data from flight tests.

The research problems considered by the Division include those associated with low-speed flight, particularly landing and take-off, as well as performance, stability and control at transonic and supersonic speeds. The aircraft used in this work fall into three categories: aircraft which differ from standard only by the inclusion of special test instrumentation (for example, a Hunter aircraft instrumented to measure tail-loads); standard aircraft modified by the incorporation of special devices and intended mainly as test vehicles (for example, the Meteor aircraft with jet deflexion); and aircraft designed and built specifically for research purposes (for example, the Rolls-Royce 'Bedstead' and Short *S.C.*1 designed to study the stability and control problems of vertical take-off and landing, and transition to normal flight).

The 'flight simulator', now under construction, is basically an analogue computer capable of solving continuously the equations of motion of an aircraft under various conditions of flight, and presenting this information both as records on paper, and as a visual display similar to that experienced by the pilot in flight. It can be used for studying the behaviour of a projected design and the pilot's reaction to it, under a wide range of conditions.

Naval Air Department. The Royal Navy has its own special problems arising from the requirement that its aircraft shall operate from carriers. While naval aircraft, in common with all military aircraft, have steadily increased in weight, size and speed, there can be no comparable increase in the size of the ships from which they operate. Thus there is a continuous and exacting problem of maintaining compatibility between the carrier and its aircraft. Important items of research on naval aircraft include the development of devices such as boundary-layer control to reduce take-off and landing speeds and the development of a technique for assessing the view from an aircraft cockpit at various angles of incidence during the approach phase.

The greater part of the Royal Aircraft Establishment's flight research work on helicopters is centred in the Naval Air Department. In addition to the problems of operating from moving ships, studies are made of the problems of stability and control, with particular reference to all-weather flying in civil and military operations.

The major experimental facilities of the department include a 200-ft. stroke, steam-powered, slotted-tube catapult. This is set in a deck some 5 ft. above ground-level, so that aircraft can be launched into space as off the bows of a carrier. The main purpose of this catapult is to 'proof' aircraft and to investigate launching techniques and phenomena. A second and similar catapult is being installed at ground-level to investigate the problems of using much higher steam pressures to obtain a greater level of energy. This second catapult will be used for launching both aircraft and dead weights, the latter being essential during the development stage of the catapult itself.

Typical aircraft-arresting gears are located in a vault below the Naval runway, thus reproducing the layout adopted in an aircraft carrier. The arresting wires, two from each gear, are stretched across the runway, as across the flight deck of a ship, and are provided primarily for 'proofing' aircraft.

The third major test facility is the safety-barrier and arrester-gear proving base. Here a deadweight trolley (representing the mass of an aircraft) is launched by means of a cordite-powered, slotted-tube catapult into an arresting wire in the process of developing arrester gears; or the conventional arresting wire may be replaced by a safety barrier net and aircraft launched into it at representative landing speeds.

Various instruments are under development in the department to facilitate operational efficiency and assist research and development. Among these are the deck-landing mirror sight which, in its present stage of development, is already a standard fitting to carriers of the Royal and United States Navies.

Blind Landing Experimental Unit. The Blind Landing Experimental Unit is, as its name implies, engaged upon the research and development of aids to enable aircraft, whether military or civil, to land at an intended destination, irrespective of weather conditions. Despite significant improvements in bad-weather aids over recent years, low-cloud base and reduced visibility still impose a very serious limitation on present-day aviation, dislocating alike the operational plans of military aircraft and the regularity and efficiency of civil airlines. Safe and successful landing in all weathers remains one of the most outstanding problems confronting aeronautical scientists and engineers to-day.

The intention is to install on the main runway the most modern aids for the landing of aircraft in all weathers, to be used not only for further experiments but also as an example of the equipments available and their performance, and to provide a model 'instrument runway'.

In common with most remote-control systems, the development of blind-approach and landing aids falls logically into two parts: the radio guidance system, which must provide steering information for the aircraft relative to an ideal path in space irrespective of weather, and the control system, which accepts the steering information and manœuvres the aircraft to a safe position for landing. The Unit employs experts in radio and automatic-control technique, and an assessment group which examines the operational success of the various aids in service and under development.

An approach and landing simulator is used for studying, on the ground, the problems of the transition from instrument flight to visual flight, examining, for example, the effects of forward speed, downward view and changes in aircraft flying characteristics.

Equipment is currently available which allows approaches to be made with an automatic pilot flying the aircraft down a radio beam to a height of about 150 ft. above the ground, the pilot needing only to take over the final landing, using the approach lighting pattern for visual guidance. The present programme is aimed at eliminating this final visual phase of the landing and devising techniques for landing completely blind.

EXPLORATION OF THE DEEP OCEAN FLOOR

FOUR widely different aspects of deep ocean exploration were discussed at a session of Section A (Mathematics and Physics) of the British Association for the Advancement of Science during its recent meeting at Dublin. The discussion was held on September 10, with the president of the Section, Prof. T. G. Cowling, in the chair. The methods of exploration that were described included seismic refraction shooting, underwater photography, the analysis of magnetic spherules found in deep-sea sediment and, finally, the examination of the oceans from manned bathyscaphs.

The seismic method of exploration was described by Mr. R. D. Adams, of the Department of Geodesy and Geophysics, University of Cambridge. An explosive charge is fired in the sea, and the resulting sound waves travel out through the various layers of rock beneath the sea-floor. By measuring the time taken for the sound waves refracted through these rock layers to reach receivers at distances of several miles from the explosion, the thicknesses of the various layers may be determined, together with the velocities of sound in them. By comparing these velocities with those measured in rocks of known geological composition, an idea can be formed of the type of rock that underlies the oceans.

Mr. Adams then described the typical structure found under deep ocean basins. In these areas the depth of water is generally between four and five kilometres. At the floor of the ocean we find a layer of loosely packed sediment which may be as much as one kilometre thick. Beneath this is a layer of more solid rock, which may be a consolidated sediment or perhaps volcanic lavas. This layer is one to two kilometres thick and overlies a further layer of what is probably a basaltic igneous rock. Finally, at a depth of approximately eleven kilometres under the surface of the sea, and six kilometres under its floor, rock is encountered for which the velocity of sound is the same as that observed at a depth of some thirty kilometres under the continents. This discontinuity of velocity is taken to mark the boundary between the Earth's crust and its mantle. Thus, the seismic method of exploration gives us an idea of the structure of the sub-oceanic crust, and shows that this crust is considerably thinner than that under the continents.

Magnetic measurements may also be used for exploring submarine structure. Mr. Adams spoke briefly of the nuclear spin or 'proton' magnetometer that was used at sea during the 1956 summer cruise of R.R.S. *Discovery II* (see *Nature*, 180, 10; 1957). Protons in a sample of water behave as small spinning magnets, and can be made to precess about the direction of the Earth's magnetic field. The frequency with which they do this is directly proportional to the strength of the field; hence by measuring this precession frequency the strength of the Earth's magnetic field may be easily and accurately determined. In this way, magnetic anomalies related to submarine structure may be traced.

The next speaker was Dr. A. S. Laughton, of the National Institute of Oceanography, who described the exploration of the ocean floor by echo-sounder and underwater camera. He explained how the development of the acoustic echo-sounder had enabled continuous profiles of the depth to the sea floor to be obtained, instead of the isolated wire soundings that previously had been the only indication of depth. From these soundings it is found that once the edge of the continental shelf is passed, there exist vast abyssal plains which are flat to one part in one thousand over distances of several hundred miles. By contrast, regions of extreme ruggedness have been mapped, and there are also areas of an intermediate type of topography. Large canyons are also found, which Dr. Laughton suggested might be due to turbidity currents. These are turbulent suspensions of sediment in water, which are capable of cutting through the continental shelf.

Dr. Laughton then showed a series of photographs of the ocean bottom, taken with the underwater camera which he has developed. The camera is lowered into the sea on a framework which also supports a light source and an acoustic device for transmitting a sound signal back to the surface every time a picture is taken. The camera is triggered when a weight hanging beneath it strikes the sea floor. The operator at the surface then hears the sound pulse, and raises the camera a few fathoms before lowering it again to take the next picture.

The first photographs shown were of a relatively smooth ocean bottom at a depth of 2,600 fathoms. Tracks of small animals were seen in the bottom sediment. A most interesting series of photographs was taken in water of decreasing depth while the ship drifted over a seamount to the north of Madeira. Loose boulders, areas of sediment, and outcrops of rock were visible at various depths. Some indications of bottom life were observed at all depths, but these became more abundant as the depth decreased. In the photograph reproduced herewith (Fig. 1), the level bottom of globigerina ooze shown is typical of large areas of the floor of the ocean basins. The mounds, which are up to a foot in diameter, result from the burrowing activities of bottom-living animals. To the left is a track, outlined by 'foot-prints' made, possibly, by a holothurian. Finally, Dr. Laughton showed three colour slides of the bottom, which revealed an unexpected variety of colour, especially red.

The next paper was by Messrs. A. A. Smales and D. Mapper, of the Analytical Chemistry Group, Atomic Energy Research Establishment, Harwell. Mr. Mapper read the paper, which was entitled "Neutron Activation Analysis of 'Cosmic' Spherules from Marine Sediment". He described a collection of magnetic spherules, of mean diameter 44 microns, which have been found in deep-sea sediment. Spherules of similar appearance have been collected from the atmosphere, and the aim of this work was to carry out a chemical analysis of spherules collected from different sources, for comparison among themselves and with material of known meteoric origin.

The amount of material available for this analysis is extremely small; in some cases the total weight of a sample is only ten micrograms. The analysis of such small amounts of material by conventional chemical means would be extremely difficult.

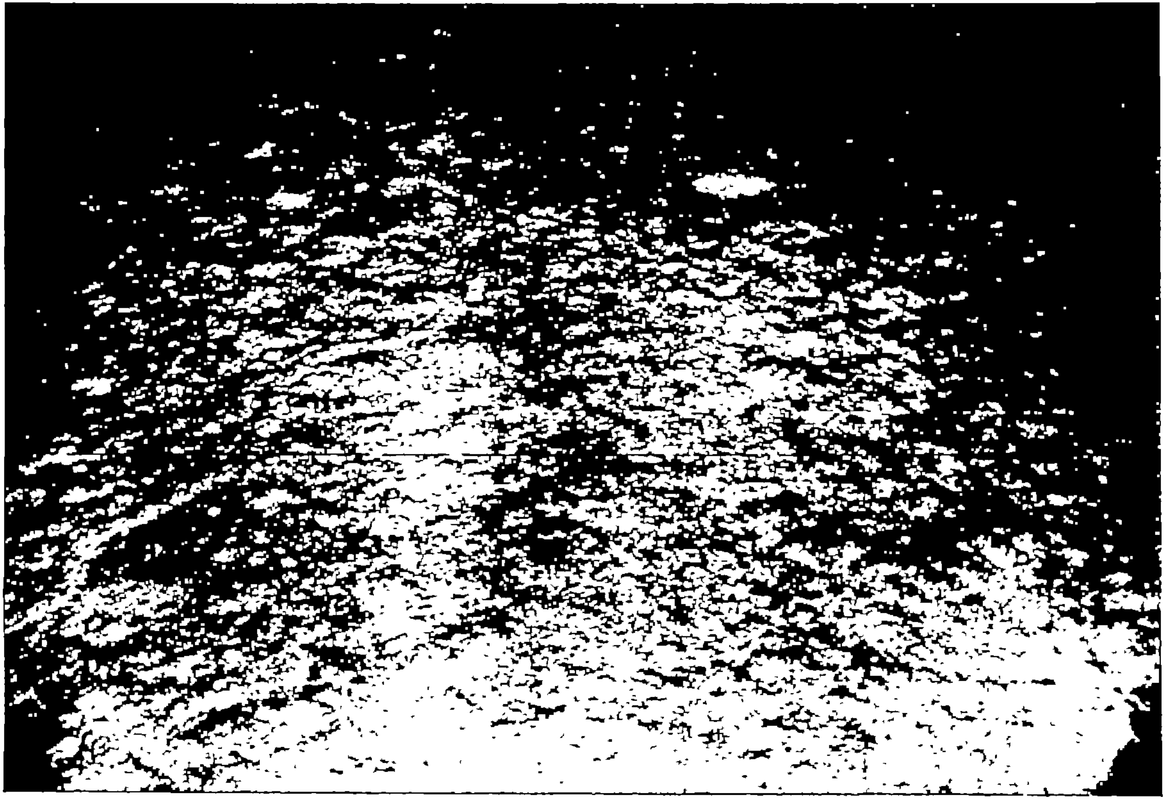

Fig. 1. [Photograph by Dr. A. S. Laughton taken at station 3461.1, position 36° 36′ N., 17° 18′ W., depth 4,670 metres. Area of picture 3 m. × 5 m.

The method of neutron activation consists of bombarding the specimen with slow neutrons in a nuclear reactor, thus inducing certain elements to form radioactive isotopes. After irradiation the sample is dissolved in a solution containing comparatively large amounts of the stable isotopes of the elements which are sought in the analysis. These act as carriers for the radioactive isotopes, and after thorough mixing a chemical separation is effected in which the radioactive isotopes from the sample remain with their carrier elements. The total amount of radioactivity found in each element is independent of the amount of carrier used, and enables the amount of this element contained in the original sample to be calculated. This method is free of the contamination difficulties associated with the conventional methods of chemical analysis of small samples. In practice, the amount of each element present in the sample is determined by using a standard specimen containing a known amount of the element, and comparing the activities of sample and standard after both have been subjected to the same amount of radiation. The sensitivity of the method is such that quantities as small as 10^{-12} gm. of certain elements can be detected. For cobalt and copper the minimum detectable quantities are 6×10^{-12} and 6×10^{-11} gm., respectively.

By this method samples of four types of spherules were analysed for nickel, cobalt and copper. The neutron activation method is unsuitable for the detection of iron, so the iron content was determined colorimetrically using a spectrophotometer. The four samples were: (1) spherules extracted from deep-sea sediment cores collected in the Pacific Ocean; (2) spherules extracted from a manganese nodule found in one of the cores; (3) spherules extracted from rainwater collected on the coast of Sweden; (4) spherules extracted from sand in the River Danube near Vienna.

The composition of meteoric material can be determined in the laboratory, and it is found that iron, nickel and cobalt constitute 99 per cent of iron meteorites. The ratio of the amounts of nickel to copper, nickel to cobalt, copper to cobalt and nickel to iron found in these iron meteorites was compared with the values of these ratios found in the four types of spherules. A definite similarity was found between these ratios for the iron meteorites and the spherules of marine origin. The spherules collected from rainwater and from the Danube, however, show no chemical similarity to the meteoric matter.

The dangers of ascribing a cosmic origin to spherules collected on land must not be overlooked. It appears that these particles may be industrial by-products carried in the atmosphere. There is, however, no chemical objection to attributing a cosmic origin to those spherules discovered in deep-sea sediment.

In the final paper, Dr. Robert S. Dietz, of the U.S. Office of Naval Research, Washington, described a descent that he had made in the bathyscaph *Trieste* to a depth of 1,100 metres near the Isle of Capri. Owing to indisposition, Dr. Dietz was unable to present his paper himself, and it was read by Commander Dean Farnsworth.

This method exploring the deep ocean bottom is the most personal that has yet been used. Dr. Dietz stressed the value of being able to see the bottom, rather than having to rely on the evidence of single photographs or the movement of television cameras. He briefly described the bathyscaph, for the construction of which M. Jacques Piccard was largely responsible. The craft is similar in principle to the lighter-than-air balloons designed by M. Piccard's father. The buoyancy is obtained by using a float filled with petrol, and, by adjusting ballast and releasing small quantities of petrol, the trim of the craft may be altered so that it will ascend or descend at the will of the operator. Below the float is a cabin, two metres in diameter, which will hold two men. Two conical windows of 'Perspex' permit observation from the cabin.

The depth of 1,100 metres is the greatest that is available in the neighbourhood of Capri, from where the bathyscaph is now operating. The cabin is designed to withstand a pressure equivalent to 6,000 metres of water, and as the petrol compartment of the float is open to the water, this is not affected by changes of pressure. There is thus no reason why the craft should not be able to descend to all but the deepest oceanic areas.

Dr. Dietz described in some detail the descent he had made. The dive lasted two and a half hours and included about forty-five minutes on the bottom. Some light was visible down to a depth of 525 metres. At greater depths than this, floodlights were switched on intermittently. Some scattering particles, presumed to be zooplankton, were observed at all depths, but the maximum amount of life was found between 500 and 700 metres. The sea bottom appeared to be composed of soft brown mud, and there was little evidence of bottom life. Three small fish were seen near the bottom, however, and some mounds and burrows similar to those photographed by Dr. Laughton were observed. During the more rapid ascent, which took only forty minutes, a turbulent eddy of water travelling with the bathyscaph made observation difficult.

In the short discussion which followed the papers, Prof. T. G. Cowling asked Dr. Laughton whether the flat areas of sediment found on some parts of the ocean floor would cover a buried topography of the basement rocks. Dr. Laughton replied that this was almost certainly the case.

Dr. B. J. Mason remarked that he was not surprised to learn that magnetic spherules of industrial origin were transported large distances from the areas where they were liberated into the atmosphere. In his work he had had experience of salt particles from the sea being carried several hundred miles inland.

R. D. Adams

POWER FROM NUCLEAR FUSION

A SESSION of Section A (Physics) of the British Association was held in Dublin on September 6 under the prophetic title: "The Industrial Applications of Thermonuclear Reactions". This was under the chairmanship of Prof. T. G. Cowling, and followed his presidential address on "Stellar Energy and Stellar Evolution", which had included a discussion of thermonuclear reactions in the stars.

Two papers were read; the first, by J. D. Lawson (U.K. Atomic Energy Authority, Harwell), consisted of a brief review of the basic physics of the reaction process and the properties of the hot gas. The second, by Sir George Thomson, dealt more specifically with the problem of containing the hot gas out of contact with the relatively cool walls of its container. After the papers there was a brief but animated discussion.

Mr. Lawson said that if an efficient method could be found of burning to helium the deuterium which occurs in water then the world's fuel problem would be solved virtually for all time. Fusion reactions between ordinary light hydrogen nuclei (protons) are important in the stars, but would be almost undetectable in any conceivable terrestrial system; reactions employing the heavy hydrogen isotopes, deuterium and tritium, on the other hand, are about 10^{25} times more probable. A mixture of deuterium and tritium is by far the most 'inflammable' fuel; unfortunately, however, tritium does not occur naturally. It can nevertheless be bred by capturing the neutrons emitted during fusion in the light isotope of lithium, which decays into tritium and helium. Lithium is not a common metal (reserves are probably comparable with those of uranium), and the ultimate aim must be to use a cycle based on deuterium. The rate of reaction for this cycle is about one hundred times less than that for the tritium/deuterium cycle, and the problem of making a power-producing system is considerably more difficult.

Temperatures of a few million degrees are required for fusion reactions to be detected, but for appreciable power to be produced at least a hundred million degrees is necessary. At such temperatures the gas is completely ionized. Radiation is in the form of bremsstrahlung (or 'free–free' electron transitions); its intensity increases as the square root of the temperature, and is proportional to the volume of the gas and the square of the density. This departure from the behaviour of a 'black body' is due to the fact that the range of the photons in the gas is very large compared with the linear dimensions of the system, so that the gas is almost transparent. Now the rate of reaction is also proportional to the volume and the square of the density, and hence the ratio of reaction power to radiated power is a function of temperature only. The two are equal at the 'critical temperature', which is about 150 million deg. for deuterium and 30 million deg. for a tritium/deuterium mixture.

It does not follow, however, that if a mass of fuel is heated to the critical temperature it can be 'set off', as in chemical explosion or combustion. The reason for this illustrates another difference between terrestrial and celestial systems; the ranges of the reaction products are very long, so that the neutrons are bound to escape from the gas without imparting their energy to it, though the charged reaction products can in principle be retained by means of suitable electric or magnetic fields.

The discussion so far illustrates some of the basic features of the reaction process, and indicates the difference in scale between a fusion reactor on one hand, where mean free paths are long compared with the linear dimensions of the system, and stars on the other hand, where the mean free paths are relatively short.

The central problem, however, is not that of producing a hot gas, difficult though this is, but of devising a system which produces more power than it consumes. A fission system needs no power to prime it, since, once a suitable lattice of fuel and moderator is assembled, heat appears. In a fusion system, on the other hand, electrical energy is required to heat the gas and to provide external magnetic fields. It is no use, for example, making a system which consumes one megawatt of electricity and only produces a further megawatt of heat, since some three megawatts of heat are required in the first place to produce one megawatt of electricity. Conditions for a favourable power balance are very stringent indeed; the gas must be heated above the critical temperature in almost complete isolation from the walls for long enough for at least a few per cent of the nuclei to be burnt.

Mr. Lawson ended by saying that the problems still to be solved appear at the moment to be formidable, and that it is not yet clear which road, if any, will lead to success.

Sir George Thomson then spoke on the problem of containing the hot gas. He started by saying that it takes a great deal of energy to heat the gas to the required temperature of 10^8–10^9 deg., and that this heat must not be allowed to escape until a substantial fraction of the gas has been burnt. For the densities likely to be used, say, 10^{14} particles/cm.^{3}, deuterium must be contained for about a second if a net power yield is to be obtained.

A gas in the completely ionized state which occurs at these temperatures is known as a 'plasma'; the mean free paths of the particles are very great, and the electrical conductivity may exceed that of copper at room temperature. In consequence of this high mean free path one cannot hope to keep the gas together by the entanglement with each other of the particle motions; an attempt to use this method would result either in a bomb, or in a system of quite impractical size.

Now heat can be lost by radiation, conduction and convection. Radiation losses are serious, but acceptable; this is fortunate since there seems to be no way of preventing them. Loss by conduction, on the other hand, would be prohibitive if nothing were done to prevent it. Sir George then did a simple calculation to show that, for a density of 10^{14} particles/cm.^{3} and a temperature of 10^8 deg., loss of heat by conduction from a sphere would exceed that by radiation unless the radius were greater than 100 km.

At first sight, one might hope to gain by departing from a Maxwell–Boltzmann gas. This is not possible, however, since the scattering cross-section greatly exceeds that for the nuclear reaction in deuterium, and consequently the ions will achieve a fair approximation to equilibrium if the high temperature is sustained long enough for a substantial fraction of them to react. In these circumstances Boltzmann's relation between potential energy and density will hold roughly, and this shows that if the density at the edge is to be really small compared with that at the centre there must be a potential difference between these which is at least a substantial multiple of kT/e, where k is Boltzmann's constant.

This shows that containment is ultimately by electric fields, though this fact may be well concealed. Containment by electrostatic fields applied externally is indeed impossible, but large internal electric fields can arise from a very small separation of positive and negative charges. A field so directed as to stop positive ions from striking the walls will impel electrons to do so; this must be stopped, and it is hoped to achieve this by anchoring the electrons by means of a magnetic field. Electron orbits in the presence of a magnetic field are 'coiled up' and the rate of diffusion is greatly reduced. If, however, an electric field is also present the particles move in trochoidal orbits, in an average direction perpendicular to both the electric and magnetic fields. Scattering does indeed result in a gradual shift of the orbits, which are pushed downhill, so to speak, by the electric field, but when the magnetic field is strong this process is very slow. The steady state predicted by the Boltzmann expression will not in practice even be approached by the electrons.

A full analysis of the behaviour of the plasma under the action of both electric and magnetic fields would be very complicated. However, in the special case of the steady state where the conductivity of the plasma is high, the relatively simple result is obtained that a current at right angles to the magnetic field will cause a gradient of pressure perpendicular to both and equal (in suitable units) to their product. The current is roughly what it would be if there were no magnetic field. It remains to adjust this gradient of pressure so as to keep the gas away from the walls of the vessel. One way of doing this is to use the 'pinch effect', which occurs when a heavy current is passed through a gas contained in a cylindrical vessel. The current elements attract one another, and a narrow current-channel forms away from the walls of the cylinder. Another way of looking at this is to regard the lines of force due to the current, which form rings round it, as possessing a tension equal to $H^2/8\pi$ (where H is the magnetic field).

The drawback of this arrangement is that the current-channel is unstable. If for any reason it bends, the magnetic lines become crowded together inside the bend; this increases the magnetic pressure there and the bend is accentuated. It is not easy to avoid this, which may be an outstanding difficulty.

Another method is to use a magnetic field produced externally which might, for example, be arranged to go tyrewise round a torus. The setting up of such a field will produce currents in the gas, this time round the cross-section of the torus. Such currents have a magnetic field which tends to neutralize the applied field inside them, and the gas at the centre is held in by the sideways pressure of the tyrewise lines of force, which is still strong in the outer parts of the cross-section. Here again instabilities are troublesome, although it seems that a combination of the two sets of currents may have possibilities.

The third form of heat-loss, by convection, is essentially associated with turbulent motion, and does not occur in a steady state such as one might hope to obtain in a heated plasma. Where instabilities occur, however, as in a pinched discharge, one would expect large losses of a convective character due to masses of gas being thrown against the walls. This is one reason why instabilities are undesirable.

Finally, how can energy be extracted from the hot gas? The heat transferred through the walls of the containing vessel could be used for raising steam, but a more attractive possibility is to make use of the magnetic properties of the plasma to induce electrical power directly in some external coupled circuit. It is not yet clear how this could be done, but the possibility exists.

Sir George ended by saying that he had sufficient confidence in the ingenuity of electrical engineers to believe that, since no fundamental reason had been found in ten years which made a fusion reactor impossible, this amounted to proof that it could be made.

Among the topics raised in the discussion after the talks was the possibility of using thermonuclear neutrons for breeding fissile material, and the point was made that this might be worth while even if the thermonuclear reaction cycle itself was not self-sustaining. It is, however, too early yet to say how this would compete with 'conventional' breeder systems.

Asked whether power might be achieved using the 'cold fusion' process, whereby the hydrogen and deuterium nuclei in a mesic molecule coalesce and fling out the meson with high energy, Mr. Lawson said that it was unlikely that a meson, sufficiently long lived to make such a process economical, existed. It was agreed, however, that this was a very interesting phenomenon, and showed that quite unexpected things may still happen.

The discussion was not entirely satisfactory, however, since some of the most interesting questions could not be answered for reasons of security. There is no doubt that Prof. Cowling echoed the feelings of the meeting when he said, in thanking the speakers, that he looked forward to the day when it would not be necessary to answer questions by referring only to the latest *published* information.

J. D. LAWSON

THE DEFENCE RESEARCH BOARD, CANADA

By C. A. POPE

THE Defence Research Board, Canada's largest scientific organization, celebrated its tenth anniversary recently.

During the later stages of the Second World War, the efforts of Canadian scientists indicated that research could provide vitally important support to the Armed Forces; and the desire of the National Research Council and other scientists involved to return to civilian research pursuits made obvious the creation of a permanent defence research organization. Hence was born the Defence Research Board on April 1, 1947. The first chairman was Dr. Omond M. Solandt, a youthful, war-time operational research scientist, who was succeeded in March 1956 by Dr. A. Hartley Zimmerman, previously a member of the Defence Research Board and vice-chairman of the organization for about a year.

The Board is believed to be unique as a scientific body because it is directed by civilians although integrated within the Department of National Defence, and it has surmounted successfully a series of growing pains and has achieved international recognition for its efforts on behalf of defence research.

Among the problems overcome during the first ten years of the Board's existence were the initial phase of organization, the establishment of a carefully planned scientific programme—interrupted by urgent Korean War requirements—and a widespread re-organization following the end of hostilities with emphasis on new and increasingly important military fields.

The keystone of defence science in Canada is the Defence Research Board itself, which consists at present of fourteen members, six of whom are *ex-officio* and six of whom represent Canadian science both from the universities and from industry. The chairman and vice-chairman are permanent, salaried members of the Board. The chairman is appointed by the Governor-General-in-Council; his status is that of a chief of staff and, as such, he sits on the Chiefs of Staff Committee. He possesses many of the financial and other powers of a deputy minister, since he reports directly to the Minister of National Defence.

The Board operates with three main objectives in mind: (1) To use existing Canadian research and development facilities wherever possible to meet the needs of the Armed Forces. (2) To maintain collaboration with the United Kingdom and United States on a partnership basis. (This permits the Board to concentrate its efforts on a limited number of problems of particular importance to Canada or for which Canada possesses unique resources or facilities.) (3) To promote in every way possible the progress of standardization, a subject of vital Canadian concern.

The value of the Defence Research Board's physical assets, comprising mainly eleven well-equipped permanent scientific laboratories, totals about 32,000,000 dollars. Almost 4,500,000 dollars was invested in the facilities which existed at Valcartier, P.Q., and Suffield, Alta., when they were Armed Services' establishments prior to 1947. New construction during the past decade, therefore, at these and at the Board's other establishments represents a total expenditure of about 27,500,000 dollars. The resulting modern research facilities will help to serve for many years to come the defence scientific interests of Canada.

The total appropriation requested for defence research and development in 1956–57 was almost 80,000,000 dollars, of which approximately 24,000,000 dollars will be used for research. This sum covers the operational costs of the Board's establishments and its liaison offices in London and Washington, and its annual 1,000,000 dollars for its programme of grants and contracts for fundamental research with Canadian universities. The remainder of the appropriation covers the development activities of the three Services.

The staff of the Defence Research Board has increased from a handful of scientists, seconded Service officers and administrative personnel early in 1947 to a total of 2,800, of whom 650 are employed in professional categories. In addition, scientists and others with highly specialized knowledge from the scientific community sit voluntarily in consulting capacities on a wide variety of panels and committees concerned with the Board's programme.

The investigations carried out by the Defence Research Board involve a variety of scientific disciplines and fields. The research areas concerned include geophysics and the Arctic, electronics and telecommunications, medical and environmental protection, materials, aeronautics, civil defence, operational research and guided missiles. Studies and appraisals of equipment and weapons of the three Armed Services are maintained on a continuous basis with the view of developing new items and improving existing ones.

The Board's naval research activities are carried out at the Naval Research Establishment and the Pacific Naval Laboratory in Dartmouth, N.S., and Esquimalt, B.C., respectively. The weapons programme is concentrated at the Canadian Armament Research and Development Establishment at Valcartier, P.Q., and investigations in the methods of protection against animal diseases are carried out at a small establishment on Grosse Ile in the St. Lawrence River near Quebec City.

In Ottawa, the Defence Research Telecommunications Establishment and the Defence Research Chemical Laboratories are just beyond the eastern and western approaches to the city, respectively. Headquarters activities are carried out at National Defence Headquarters, where an Operational Research Group is also co-ordinated with the Defence Research Board Services programme in this new scientific field.

The Board's biological research programme is conducted at the Defence Research Kingston Laboratory in Kingston, Ont., and its medical activities at the Defence Research Medical Laboratories at Downsview, Ont. The latter establishment is concerned with investigating methods of using the Serviceman's physical capabilities to their fullest extent and with matching them to the complex machines he operates, rather than with curing the ill.

Activities at the Defence Research Northern Laboratory at Fort Churchill, Man., involve Arctic research. Until recently, emphasis was placed on developing techniques and methods of assisting troops to operate effectively under severe weather conditions. Cold-weather trials involving both men and equipment have been particularly important fields for study. The Laboratory now provides facilities for visiting scientists from Canada, the United Kingdom and the United States engaged in conducting northern investigations. During the next two years, the Laboratory will serve particularly as a scientific base for many of Canada's International Geophysical Year operations. Scientists of the Board will assist an American rocket team in launching a series of missiles with instrumented nose cones in support of upper atmospheric research.

At Suffield, Alta., near Medicine Hat, staff scientists conduct trials and experimental activities connected with the defensive aspects of biological, chemical and flame warfare. An important entomological programme, completed recently, resulted in the development of useful methods of controlling forest and crop pests by air-spray techniques. The station is ideally located on the prairies for trials and experiments, and its thousand square miles of rolling terrain provide unsurpassed physical facilities for such operations.

The Board has gained international recognition for some of its scientific activities, several of which promise useful civilian implications. Among these are anti-corrosion techniques to protect ships' hulls, a rocket-type anti-tank weapon with impressive accuracy, development of the detection unit installed in the Mid-Canada Early Warning Line, upper atmospheric research, development of ration and survival packs and dehydrated food techniques and an active role in promoting in Canada knowledge of guided missiles.

Recent changes in emphasis in the Board's scientific programme have involved an increasing interest in atomic activities, including the participation by members of its staff in last year's British–Australian atom bomb trials, an expanding use of electronic aids in many fields of defence science and in co-operation with the United Kingdom and the United States, a series of studies concerning certain phases of the defence against intercontinental ballistics missiles and, particularly, methods of countering attacks by such weapons.

The work achieved by scientists of the Defence Research Board during the past ten years provides them to-day with the confidence necessary for their second decade of operations.

OBITUARY

Mr. Atholl Blair, C.B.E.

MR. ATHOLL BLAIR died suddenly at his home in Belfast last month at the age of seventy-one. He had spent a lifetime in the service of Messrs. Harland and Wolff, and was probably the world's leading builder of all forms of marine propelling machinery. When he retired in 1953 from the firm with which he had served his apprenticeship as an articled pupil he occupied the position of engine works manager and was a director of the firm. His services were retained as a consultant, however, and he remained a most active man until his sudden death.

Atholl Blair was the son of the late Sir Robert Blair, a distinguished educational administrator who occupied the position of chief education officer to the London County Council. Before succeeding to that appointment Sir Robert had gone to Ireland at the turn of the century to set up the system of technical education in that country, and his son Atholl, after going to school in Edinburgh and Dublin, attended the City and Guilds Engineering College, where he studied under the late Prof. Dalby.

With this background it is not surprising that Mr. Blair at all times took a keen interest in technical education, and it is characteristic of the man that, long before industry began to show its present concern in this vital activity, Mr. Blair was much occupied in it from the point of view of his apprentices and of their welfare. He was the first chairman of the Joint Committee for the award of National Certificates in Northern Ireland and later became a member of the Committee of the Belfast College of Technology.

Atholl Blair's professional career was a most impressive one. His contribution to the national effort in two world wars was massive. He expected a great deal from his subordinates and demanded more from himself. For all this he will be long remembered, but those who were privileged to share his friendship will greatly miss the loyalty and warm human understanding of a man of sterling character. In his busy life he had not much time for taking part in formal activities outside his work, but he had a sound knowledge of art and a keen interest in the world around him. He at one time prepared to take up architecture as a career, and must have derived satisfaction from the fact that one of his sons became an architect and the other an engineer.

D. H. ALEXANDER

NEWS and VIEWS

Orbit of the Artificial Earth Satellite

THE artificial Earth satellite was launched from the U.S.S.R. on October 4. By a considerable feat of improvization, Mr. Martin Ryle and his team at the Mullard Radio Astronomy Observatory near Cambridge have been able to record the radio signals transmitted by the artificial satellite from October 5. Improvement of the technique has provided results from which a preliminary orbit has been calculated (*Brit. Astron. Assoc. Circular*, No. 390; October 15, 1957):

Epoch		October 8–9, 1957
Inclination	i'	64 9° (from two methods)
Eccentricity	e	0·06
Period	P	96m. 2s.; − 1 5s. a day
Maximum height		970 km. (630 mi.), at latitude − 45° approx
Minimum height		190 km. (118 mi.), at latitude + 45° approx
Precession of node		3° 40′ a day.

A report from the United States gives the maximum height of the orbit above the Earth as 583 miles and the minimum as 143 miles, and states that the carrier rocket was travelling three minutes ahead of the satellite on October 12. An important feature of the elliptical path, which will enable valuable information of the outer atmosphere to be obtained, is that it runs into and then out of the ionosphere.

A telegram from the Bureau of the International Astronomical Union gives particulars of an equatorial ellipse for the artificial satellite computed by Lautman, Slowey and McCrosky at the Smithsonian Institute, namely:

Epoch, October 9·405 U.T. 1957

v	266° 24′	(True anomaly)
ω'	61 47	Equator 1957·0
Ω'	227 20	
i'	64 16	
φ	2 56	(e = 0 0512)
a'	1 08908	(in equatorial radii of Earth)

Mr. D. H. Sadler reports, following observations at the Royal Greenwich Observatory by K. C. Blackwell and W. A. Scott, that the carrier rocket is now visible in the British Isles in the morning twilight, the magnitude varying between about − 1 and + 3, moving at a height of about 430 km. from north-west to south-east. On October 13 it was approximately over Bournemouth at 5h. 26m. U.T., the track moving south-west, parallel to itself, about 200 km. a day. The time will be earlier by about two or three min. a day. The satellite itself follows behind the rocket, at present by about five minutes.

New Atomic Patents

THE specifications of three patents developed within the United Kingdom Atomic Energy Authority are about to become generally available. They are all connected with the design of the graphite structure used in the building of Calder Hall nuclear power station. A number of factors influence the design of graphite moderators, one of the most important being the phenomenon of growth under irradiation (generally referred to as Wigner growth) and this is affected by the quality of graphite, the direction of grain, neutron bombardment and temperature, and in turn led to careful consideration of the design of individual blocks. The production of the graphite itself was the subject of intensive study, and quality varies between the outer perimeter and the centre. The patents involved, which also include details of fuel element support, are: No. 784,291, open for inspection on October 9; No. 784,292, open for inspection on October 9; No. 785,876, open for inspection on November 6. Specifications may be obtained from the Patent Office (Sales Branch), 25 Southampton Buildings, London, W.C.2, price 3s. 6d., including postage.

Proton-Synchrotron at Harwell

THE Governing Board of the National Institute for Research in Nuclear Science announces that a contract has now been signed for the supply of the magnet yoke which is a major component of the 7,000 million eV. proton-synchrotron being built for it on a site adjacent to the Atomic Energy Research Establishment at Harwell. The contract has been signed with Messrs. Joseph Sankey and Sons, Ltd., who have undertaken to supply the 340 steel blocks required, each weighing twenty tons, at a total cost of more than £1,250,000. The special steel required will be supplied by the Steel Company of Wales.

Thermionic Valves

ON October 3, Mr. T. E. Goldup delivered his inaugural address as president of the Institution of Electrical Engineers for the session 1957–58; his main subject being thermionic valves. After briefly tracing the history of the great strides made in this field over the past fifty years, he dealt in some detail with several examples of modern developments, and with the new manufacturing processes it has been necessary to devise for the successful and economic exploitation of the results of research; these processes were illustrated by means of a short film. From the simple beginnings of Fleming's diode and de Forest's triode the field of thermionic valves has extended to include microwave valves, television camera tubes, transistors and 'masers', and a whole family of related devices which have become an all-important factor in every branch of engineering and science—a factor which more than any other has not only shaped but determined the progress in electrical engineering as it is known to-day. Mr. Goldup also referred in his address to the urgent need for a great increase in the number of adequately trained engineers and scientists, and discussed some of the associated problems of technological education. He concluded by directing attention to the moral responsibility which, in his opinion, scientists and engineers should assume for the manner in which their work is used.

The Australian Journal of Science

COMMENCING with Vol. 20 (July 1957), the *Australian Journal of Science*, the organ of the Australian and New Zealand Association for the Advancement of Science, will be published nine, instead of six, times a year. The *Journal* is issued free to Fellows and annual members of the Association; for non-members the annual subscription, formerly 25*s*., is increased to £A2; but the cost per issue remains unchanged at 4*s*. 6*d*. Meetings of the Association are held every eighteen months and the report of each meeting is published in three special issues of the *Journal* so that two out of every three volumes of the *Journal* contain twelve numbers. The report of the proceedings of the thirty-second meeting of the Association, which was held at Dunedin during January 16–23, 1957, is published in the three special issues of Vol. 19. The first (19, No. 3*a*; January 1957) contains a list of the officers of the meeting; details of the general programme; the presidential address, "Biology and Medicine", delivered by Sir Macfarlane Burnet; the Liversidge Lecture, "Molecular Hydrodynamics: the Diffusion of Molecules and Ions through Liquids", by Prof. R. H. Stokes; and the addresses of the presidents of the Sections: A (Astronomy, Mathematics and Physics), B (Chemistry), C (Geology) and D (Zoology). The titles and authors of the other papers delivered in these four sections are also included, in addition to an appreciation of Prof. A. P. Elkin, the recipient of the Mueller Medal for 1957.

Research for Industry

THE London and Home Counties Regional Advisory Council for Higher Technological Education has issued a further survey of industrial research in progress in technical colleges in the region in 1956 under the title "Research for Industry" (Pp. 20. 1*s*. 6*d*.). The survey shows that since the previous report was issued in 1954, covering the period 1947–52, there has been a marked development of collaboration between industry and the technical colleges. The report lists the investigations in progress, their sponsors and the technical college where they were undertaken. Besides work sponsored directly from industry, numerous investigations are being carried out for research associations, for Government departments, particularly the Ministry of Supply, for the Atomic Energy Authority, and for the Central Electricity Authority, while others are financed by grants from the Department of Scientific and Industrial Research. At Chelsea Polytechnic, the Medical Research Council is supporting an investigation on the preparation of substituted triazaphenanthrenes of potential chemotherapeutic value, the British Empire Cancer Campaign is paying for electro-kinetic studies of bacterial surfaces, while at Acton Technical College studies in the flow between management and industry are being conducted for the Tavistock Institute of Human Relations.

Economic Developments in the Middle East

"ECONOMIC Developments in the Middle East, 1955–56" (London: H.M.S.O. 11*s*.), is part of the survey of the world economic situation prepared by the Secretariat of the United Nations, and issued as a supplement to *World Economic Survey*, 1956. Besides chapters on agriculture, industry, petroleum, foreign trade, and on monetary and fiscal charges and the price-level, it includes a preliminary review of the economic impact of the Suez Canal crisis on the Middle East. During the period, demand for Middle East exports maintained its upward trend, chiefly for petroleum, but also notably for cotton, the share of the U.S.S.R. and eastern Europe rising and that of Western Europe declining. There were comparable increases and shifts in imports and their sources of supply. There was little change in the inflow of capital, and among development projects the major emphasis was on agriculture, irrigation and transport. Two major dams were completed in Iraq and two others in Turkey, and also the railroad from Tehrân to Meshed in north-east Iran. The annual rate of increase in production of crude petroleum rose from 12·8 per cent in 1954 to 18·3 per cent in 1955 but decreased in 1956, mainly owing to the sharp decline in the last two months of the year. Expansion of refining capacity in 1955 raised the crude annual charging capacity of the region to more than 66 million tons, and in the autumn of 1956 the twenty refineries and topping plants were operating at 50 million tons per annum, an increase of about 35 per cent over the average for 1955, when the region processed 23 per cent of its production or 5·6 per cent of the world's refined products; the figure for 1956 is probably higher. Industrial output increased sharply in 1955, but the overall increase in 1956 was probably less.

The Pacific Science Board

THE tenth annual report of the Pacific Science Board (pp. 50. Washington, D.C.: National Academy of Sciences) records that the principal scientific activity in Micronesia has been the coral atoll programme, involving an ecological approach to the study of environmental factors affecting life on coral atolls. H. J. Wiens continued his interpretive study of man and Nature in the atoll environment, and besides visiting thirteen atolls in the Marshall Islands to study the individual features of different coral atolls, he was able to obtain comparative information on the human ecology of the Marshallese to relate to his findings in the Caroline Islands. F. R. Fosberg obtained comparative information in a visit to the Maldive Islands. Three numbers of the *Atoll Research Bulletin* were issued and twelve volumes on insects of Micronesia. Field-work continued in the three-year study of the biology and ecology of Pacific island rats at Ponape, Eastern Carolines, where valuable information is being acquired on the natural history and ecology of rats, and the field team co-operated with the Trust Territory's biennial training programme for sanitary officers by conducting a programme on rodent control. A study of sea turtles by J. R. Hendrickson has special reference to measures to assure the conservation of the turtle, and support was again given to the marine biological programme of the George Vanderbilt Foundation at Stanford University, which included investigations on the relations of fishes to their environment, the study of the estuarine-mangroves and fresh-water fishes of the Palau Islands, an entomological survey of scale insects and a study of sea currents about the Palau Islands.

National Bibliography of Nigeria

"NIGERIAN PUBLICATIONS", 1956, the fifth issue of Nigeria's current national bibliography (pp. 39. Ibadan Univ. Press. 10*s*.), lists all works received under the Publications Ordinance by Ibadan University College Library during January–December 1956. These are arranged by author, works in the English language being listed first, followed by separate lists of works in the several vernaculars. There are also lists of new Nigerian periodicals, of changes of title and of those which ceased publication during the year, and finally of recent works on Nigeria and by Nigerians published outside Nigeria. The Librarian notes a sharp drop in the number of works published in Nigeria, from 599 in 1955 to 348 in 1956, half of which are now Government publications compared with 26 per cent in 1955. The vernacular languages, however, are declining; in 1956 they were responsible for only 9 per cent of the total. Creative writing is almost entirely absent.

Progressive *Verticillium* Wilt of Hops at Wye College

As stated in the recently published annual report of the Wye College Department of Hop Research, a single plant in one of the College hop gardens was found in 1956 to be infected with *Verticillium albo-atrum*. An outbreak of progressive wilt having been treated on the College farm in 1955, this new case was at once suspected to be progressive wilt. The report envisaged the possibility that if this recent diagnosis was also confirmed, Wye College might be forced to accept the status of a 'wilt farm', a step which would raise major issues of policy. During the 1957 season, no further cases of *V. albo-atrum* in hops have been found at Wye, and pathogenicity tests with the fungus from the 1956 case have been carried out by the National Agricultural Advisory Service and by East Malling Research Station. The results of these tests clearly show that this 1956 infection was not progressive wilt but was due to the non-serious or fluctuating strain of the fungus. No case of progressive wilt (caused by the virulent or lethal strain) has therefore been recorded in the College hop gardens for two years and it appears probable that the drastic control measures carried out in 1955 have been successful in suppressing the only known outbreak. In view of this, hop research will continue at Wye without any radical change in policy. Provided no further cases of wilt occur, the College Farm will in a few years be declared officially to be an uninfected area. Meanwhile the present strict regulations prohibiting visits to the gardens and the release of all planting material remain in force.

Agricultural and Forestry Research in East Africa

MANY interesting lines of work are described in the research report for 1956 issued by the East African Agriculture and Forestry Research Organization. Most of the problems under investigation are of a long-term or inter-territorial nature. This is well illustrated by the three experiments, one in Tanganyika and two in Kenya co-ordinated by the Physics Division, on the effect of changes in land-use in high catchment areas on the evenness of river flows. The factors controlling the rate of decomposition of humus have been studied by the Chemistry Division and their results appear to offer an explanation both of the beneficial effects of burning and also of the nitrate flush at the start of the rains, and it seems likely that these findings may have a fairly general application on other tropical and sub-tropical soils. In the Forestry Division, special attention has been paid to nursery and transplant bed techniques for the production of exotic softwoods. Considerable success has been obtained and demonstrations of the new methods are being made in the Territories. Measurement of the yield of grasslands has formed an important part of the work in the Animal Industry Division, and it is now realized that the size of the experimental plot needed to achieve a ten per cent coefficient of variation is much larger than was expected. This is due to the seasonal aridity, uniformity of growth comparable with that of temperate pastures being found during the rainy season only. In feeding trials with sheep and cattle the total percentage content of crude protein in the fodder proved to be the most important factor determining its digestibility, and a statistical examination of the data from all the digestibility trials in East Africa and of many other parts of the world showed this to be true of both temperate and tropical regions.

Tokyo Astronomical Observatory

Tokyo Astronomical Bulletins issued between January 20 and May 20, 1957, consist mainly of tabular matter relating to observations made at Tokyo Astronomical Observatory. No. 92 does not deal with observations, but is entitled "Some Improvements of Short Wave Receivers for Time Signal Reception"; it describes how frequency-amplitude characteristics of the receivers at Tokyo Astronomical Observatory were improved so that there has been a decrease in the delay times and wave-form distortion in order to meet the present methods of registering and request for high accuracy. No. 94, "Scanning Photoelectric Photometer and Method of Observation of Night Airglow for the International Geophysical Year", describes some improvements made in the two sets of scanning photoelectric photometers that have been in use for about four years for the observation of the green line in the night airglow at the Tokyo Observatory.

Fluorescence of Impurities

WHEN a small quantity (about 1 part in 10^5) of tetracene (the 'impurity') is added to anthracene (the matrix) the fluorescence of the anthracene is suppressed and tetracene fluorescence of high efficiency appears. With increase of the concentration of the tetracene the intensity of the tetracene fluorescence increases and that of the anthracene decreases. A similar process takes place when tetracene is added to naphthalene, or anthracene to naphthalene, etc. The emission of the impurity is said to take place by means of a transfer of the absorbed energy of radiation from the matrix molecules to the impurity molecules, and a necessary condition for this is that the fluorescence of the impurity molecules should lie at longer wavelengths than that of the matrix. The energy-transfer process in solids has most often been studied in systems of the polyacenes and related molecules. A guide to the literature connected with the process entitled "Energy Transfer in Polyacene Solid Solutions" has recently been compiled by F. R. Lipsett (pp. ii + 64. Ottawa: National Research Council, 1957. 50 cents). It is divided into six sections, dealing respectively with books on luminescence and spectra and related subjects; review articles and papers on theories of spectra; experiments on spectra; energy transfer, including exciton theory and experiments on liquid solutions, solids, glasses, plastics, inorganic compounds and gases; related subjects, including photo- and semi-conduction and electroluminescence; and experimental techniques, including crystal growth and sample preparation. The guide is by no means exhaustive, but the papers have been carefully selected, the criterion for the selection being their usefulness in elucidation of the energy transfer process.

Perkin Centenary Trust Awards

The Perkin Centenary Trust was established to commemorate the discovery of 'Mauveine' by William Henry Perkin in the year 1856 and to promote technical education in all aspects of the manufacture and application of colouring matters. The Trustees offer the following awards for the academic year 1958–59: (1) *The Perkin Centenary Fellowship*, for one or two years, to a graduate for the purpose of higher study. It has a value of not less than £600 per annum, and is tenable, from October 1958, at any university, technical college, or other institution approved by the Trustees. (2) *Two Perkin Centenary Scholarships*, each for two years starting in October 1958 and renewable at the discretion of the Trustees for one further year, to enable candidates employed in an industrial firm or other institution concerned with the manufacture or the application of colouring matters to receive an education at a university or technical college. Each award will have a value of £300 per annum. There is no means test for the award, and a successful candidate is not debarred from receiving the whole or a part of his normal salary from his employers during his tenure of the scholarship. (3) *Perkin Exchange Lectureships*. An appointment will be made from time to time by the Trustees to enable a senior teacher at any appropriate university, or technical college, or other institution, to visit some similar establishment overseas in order to deliver a short course of lectures. In return, a visit to a British institution by some overseas scientist will be arranged. A second appointment contemplated will permit the exchange of lecturers for a period of up to one year between comparable institutions in Britain and overseas. Further information can be obtained from the Secretary, The Perkin Centenary Trust, c/o The Chemical Society, Burlington House, London, W.1. Applications for the awards must be made by May 1, 1958.

B.B.C. Research Scholarships

The B.B.C. has awarded two research scholarships, valued at £435 per annum, to university graduates in electrical engineering, giving them the opportunity to work for a higher degree at any university in the United Kingdom. The first is to Mr. J. B. Izatt, who graduated at the University of Aberdeen. Mr. Izatt will conduct his researches at the Robert Gordon's Technical College under the guidance of Dr. E. Wilkinson and Mr. A. M. Hardie. The second scholarship has been awarded to Mr. W. A. G. Voss, who graduated at Queen Mary College, University of London. Mr. Voss will conduct his researches there under the guidance of Prof. M. W. Humphrey Davies. The scholarships, which are awarded annually, are for two years in the first instance with the possibility of extension in suitable cases. The scholarships are limited to male British subjects normally resident in the United Kingdom, and the only condition applying to the subject for research is that it must have an application to sound or television broadcasting.

Announcements

The World Meteorological Organization has posthumously awarded the annual prize created to commemorate the International Meteorological Organization to the late Prof. Carl Gustaf Rossby, of Stockholm, who died on August 19.

Prof. J. H. Gaddum has been appointed director of the Agricultural Research Council Institute of Animal Physiology, Babraham, Cambridge, as from September 30, 1958, when Dr. I. de Burgh Daly, the present director, is to retire.

Mr. P. A. Hufton has been appointed head of the Aerodynamics Department, Royal Aircraft Establishment, Bedford, and Dr. D. Kuchemann has been appointed to succeed Mr. Hufton as head of the Supersonics Division of the Aerodynamics Department.

Dr. James Reekie has been appointed chief engineer to Semiconductors, Ltd., Ilford, Essex. For the past twelve years Dr. Reekie has been in Canada, where he was professor of physics at the University of Toronto, and later, head of the Department of Physics at the Royal Military College of Canada. Prior to joining Semiconductors, Ltd., Dr. Reekie, who has been responsible for a considerable number of technical publications in the field of solid state physics, was research director in semiconductors and solid state physics for the Northern Electric Company, Montreal.

The United Kingdom Atomic Energy Authority will be unable to accept further applications to visit their establishment at Dounreay for several months. The fast breeder reactor is now nearing completion and the staff of the station will be under heavy pressure in supervising its completion and commissioning.

W. Watson and Sons, Ltd., are to hold an exhibition on the theme of "The Microscope in Industry and Research" at the Birmingham Exchange and Engineering Centre, Stephenson Place, Birmingham 2, during November 4–8. A catalogue of exhibits may be obtained from W. Watson and Sons, Ltd., 313 High Holborn, London, W.C.1, to whom all inquiries should be addressed.

The Hatfield Memorial Lecture of the Iron and Steel Institute will be held at 6.30 p.m. on November 28 in the Firth Hall of the University of Sheffield. It will be given by Prof. Paul Bastien, director of research of the Société des Forges et Ateliers du Creusot, whose subject will be "The Mechanism of the Formation of Banded Structures in Steel". Applications for tickets should be made to the Registrar, The University, Sheffield 10.

A review of Iredale's "Birds of New Guinea" was published in *Nature* of October 5, p. 675. The distributors of this work in the United Kingdom are Phoenix House, Ltd., 38 William IV Street, Charing Cross, London, W.C.2.

LATENT VIRUS INFECTIONS

THERE is increasing recognition that many virus infections, of animals, higher plants and bacteria, are present in the absence of overt symptoms and signs. Some of them become activated by the most various stimuli, and there is thus bred confusion as to the true causes of some diseases. Some insect viruses, when introduced into an insect which is not their natural host, may activate a virus latent in that host, starting off a serially transmissible disease which is not essentially caused by the virus first used. Study of these phenomena is made difficult by the lack of uniformity in the use by workers concerned of certain key words such as 'latent', 'inapparent', 'subclinical', 'masked'.

A symposium on "Latency and Masking in Viral and Rickettsial Infections" was held during September 4–6 on the University campus at Madison, Wisconsin. It was supported by the Rockefeller Foundation and the Wisconsin Alumni Research Foundation. About 225 people attended. The object was to exchange views on the mechanisms of latent infections and more particularly to try to reach some agreement concerning the proper use of relevant words. After the reading and discussing of the papers presented, there was, on each day, a more general debate under the ægis of a moderator, participated in both by a panel on the platform and by speakers from the body of the hall.

In an opening address, C. H. Andrewes (London) made a general survey of the field and put forward tentative suggestions as to the use of some important words. He emphasized, as did subsequent speakers, that the matter must be considered both at the host–parasite and the cell–virus level. He was followed by André Lwoff (Paris), who discussed lysogeny and the prophage–phage sequence as examples of latent infection of bacteria and its activation by ultra-violet rays and other stimuli. J. W. Beard (Durham, North Carolina) was much concerned about the use of the terms masking and masked virus. Shope first used the terms in virology for describing the state of affairs in which papillomata grew progressively in domestic rabbits, yet virus was hard to demonstrate except by indirect means. He believed that virus was present in a qualitatively changed state. Beard, on the other hand, held that the facts could be more simply explained by presence of virus in very small amounts: he felt that the term 'masked' should be either rigidly defined or abandoned. R. Dulbecco (Pasadena) discussed temperate phages, which readily enter into a lysogenic relationship with bacteria; and the contrasting virulent phages which lead to lysis. He proposed the terms moderate, semi-moderate and virulent for describing corresponding relationships between the host-cells and viruses of animals and higher plants. Later, sub-moderate was preferred to semi-moderate and cytocidal to virulent.

R. J. Huebner (Bethesda) described latent infections with adenoviruses, salivary viruses and herpes; he felt that there was a virus-group in which presence of intranuclear inclusions was associated with a tendency to persisting infection. J. E. Hotchin (Albany, New York) reported studies of lymphocytic choriomeningitis in mice, extending Traub's classical findings. His work supported the idea that immunological tolerance might explain how, in mice infected *in utero*, persistent infection occurred, with absence of antibody formation or tissue reaction.

F. C. Bawden (Rothamsted) discussed the varying relations between higher plants and viruses, in particular the latency of paracrinkle virus in King Edward potatoes. He was inclined to make use of the word 'commensalism'.

Several workers described latent infections of viruses in tissue culture. T. T. Puck (Denver) spoke of cells chronically carrying Newcastle disease virus; the latent infection became manifest when they were plated on to a monolayer of highly susceptible irradiated cells. F. Deinhardt (Philadelphia) had studied similar cell lines carrying Newcastle disease virus or mumps virus. It appeared that only one in fifty of cells latently infected with Newcastle disease virus would liberate active virus, yet all were relatively resistant to infection with vesicular stomatitis virus. W. W. Ackerman (Ann Arbor) described somewhat similar experiments with poliomyelitis-infected cultures; and H. S. Ginsberg (Cleveland) spoke of experiments on latent infections of cultures with adenoviruses. H. R. Morgan (Rochester, N.Y.) had kept psittacosis virus in a latent state by starving his cultures: a good nutritive medium would activate the virus and apparently certain amino-acids and water-soluble vitamins were especially effective. C. B. Philip (Montana) spoke of a similar situation in ticks infected with rickettsiæ of rocky mountain spotted fever. The rickettsiæ were non-infectious in starved ticks but could be activated by feeding or incubation.

During discussion, Huebner mentioned a latent infection of HeLa cells with a virus which finally "turned his cultures into one giant cell". This virus was propagable in eggs, and antibodies were present in all human sera except those of early childhood.

In a final session for general appraisal and definition of terms, questions at issue were batted back and forth between the floor of the house and a panel consisting of Andrewes (moderator), Bawden, Beard, Dulbecco and Lwoff. Lwoff had prepared a document containing a number of definitions, and this served as a useful basis for discussion. Since practically every speaker earlier on had used the words 'latent', etc., in a different sense, it was surprising that a considerable measure of agreement was ultimately reached. There was in fact a fair consensus of opinion on the following points.

At the host–parasite level, 'inapparent infection' covers the whole field of infections which give no overt signs of their presence. 'Latent infection' denotes those cases of inapparent infection which are chronic and in which a certain host–virus equilibrium is established. No special word was recommended to describe inapparent infections of limited duration ('infection inapparente' in Nicolle's original sense), but it was recognized that the term 'subclinical' would continue to be used for many such infections of man and other species. (Most delegates were apparently very surprised to hear that the word 'clinical' originally had reference to 'bed'.) It was suggested that the term 'latent virus' be not used: confusion would seem inevitable if the same adjective were applied to 'infection' and to 'virus', since the meaning of 'latent' would necessarily be different in the two cases.

As regards the word 'masked' there seemed no possibility of obtaining agreement. It was suggested, therefore, that its use should not be encouraged but that 'occult virus' should be used instead. Among the definitions of occult provided by the Oxford dictionary were: "communicated only to the initiated; not apprehensible to the mind". The word 'occult' should cover "the cases where infective particles cannot be detected and in which the actual state of the virus cannot as yet be ascertained". Thus we might be unable to recover virus from an infected host but might be ignorant as to whether it was qualitatively altered or present in minute quantity or mixed with antibody. We should need a word to describe our state of ignorance: other more descriptive words could be used when the reason for the occult state had been discovered.

At the cell–virus level, it was agreed that a provirus, corresponding to prophage, had not been proved to exist, but that if and when other viruses were shown to pass through cycles like that of phage, the words 'provirus', 'vegetative virus' and 'infectious virus' would be appropriate to describe the corresponding stages.

Dulbecco's term 'moderate virus' was approved to denote a virus which grew in a cell while still permitting its continued survival and multiplication: 'cytocidal' described one which killed it: 'submoderate' covered intermediate cases. Clearly, some viruses are moderate for one cell-system, cytocidal for another: so the words are only relevant to particular virus-cell systems. It is important to note also that a virus may be cytocidal for some dispensable cells in a host, yet these may be at any one time few in number so that the infection as a whole is inapparent.

The proceedings of the symposium will be published shortly by the Burgess Press, Minneapolis.

C. H. Andrewes

BIOLOGY OF THE SALMON

A SYMPOSIUM on the "Biology of the Salmon" was held on September 10 by Section D (Zoology) of the British Association meeting in Dublin.

Dr. A. E. J. Went opened the symposium with a paper entitled "Salmon Investigations in Ireland, with particular reference to the River Shannon". He pointed out that if it had been necessary to purchase salmon for investigation, progress would have been very slow owing to the great expense of obtaining fish; but fortunately a considerable amount of information can be obtained about an individual salmon by microscopic examination of its scales. The scale of a salmon is a life and birth certificate, and it was by this means that the late Rowland Southern in 1924 started his investigations into the salmon of the River Shannon which was then about to be harnessed for hydro-electric purposes.

Southern's first paper in 1928 indicated in a general way the age and growth of salmon of the River Shannon in the years 1924–26 inclusive, and afterwards the investigations into the runs of fish in 1927 and 1928 were carried on by Went, using material from salmon taken in the ancient Lax Weir near Limerick. From 1941 onwards similar material has been collected annually from salmon taken in the Thomond Weir near Limerick.

Prior to the operation of the hydro-electric plant the Shannon was predominantly an early-salmon river; that is to say, the bulk of the fish had spent two or more years feeding in the sea. Taking the year 1928 as representative of the pre-hydro-electric scheme stocks and the year 1941 as representative of the post-hydro-electric scheme stocks, the differences in the stocks may be summarized briefly as follows: (1) the average age of the smolts was higher in 1941 (2·08 years) than in 1928 (1·98 years); (2) the grilse amounted to 75 per cent of the total run of 1941, whereas in 1928 the figure was 24·7 per cent; (3) in 1941, 70 per cent of the total run occurred in the month of June, whereas in 1928 that month's catch amounted to only 27·5 per cent of the total; (4) the age of the fish in 1941 was approximately one year less than in 1928; (5) the average size of salmon entering the river in 1941 was much smaller than in 1928.

By a series of calculations it was found possible to estimate the relationship of the size of the 1928 and 1941 runs. By this method it could be shown that the grilse have not actually increased but they have remained relatively static over the years. Those age-groups of salmon which have spent two or more years feeding in the sea have been very much reduced and the present stocks of the River Shannon are about 30–40 per cent of those of the pre-hydro-electric scheme days. This change seems to be associated with the 'dewatering' of the main spawning beds for large salmon in the old channel of the Shannon between Killaloe and Limerick. This might account for the loss of the earlier running or larger fish. On the other hand, the Mulcair River, which is the major spawning tributary of the Shannon to-day, always was the major spawning ground for the smaller fish.

Adequate material has now been collected annually from 1941 to date and it has been possible to follow the changes in the sizes of the stocks and to estimate the yield (as adult fish) from a number of brood years from 1942 to 1951. Variations in the number of fish derived from the different brood years during this period have ranged from 16,100 for 1950 to 6,400 for 1942.

At this stage Miss E. Twomey took up the story with her paper, "The Age and Growth of Irish Salmon". She gave the results of investigations into the age and growth of the salmon of various Irish rivers, again using collections of salmon scales and data relating to the weight, length and date of capture of the fish concerned. Salmon in Irish rivers spend 1–4 years before migrating to the sea for the first time. The majority of fish, however, spend two years in the fresh water, the one-year old smolts generally being next in importance. Only a few four-year olds have been identified from Irish rivers.

Two types of smolts have been identified in Irish rivers, namely, those which show little or no growth in fresh water in the spring prior to the smolt descent, and those which showed considerable growth. These types have been described by Went as type *A* and type *B* smolts, respectively. All the one-year smolts were of type *B*, and in the older smolt classes both types were found; the proportion of type *A* increased gradually as the smolt age is ascended.

There is considerable variation in the length at which smolts migrate. In the Rivers Liffey and Lee they migrate at an average length of about 16 cm., whereas in other rivers they may migrate at lengths of less than 12·5 cm.

The fastest-growing fish in each river appear to migrate first, and there is generally a slight increase in the average length of the smolt as the smolt ages are ascended.

Spring fish which have spent two or three years feeding in the sea predominate in some Irish rivers such as the Liffey and Lee, whereas on the other extreme some are virtually grilse rivers; that is to say, the fish have spent less than two full years feeding in the sea. In rivers which have no lakes on their systems and with intensive commercial fisheries the proportion of previous spawners is low. This is the case of the Rivers Liffey, Lee, Inny and Kerry Blackwater. In most rivers having lakes on their systems the proportion of previous spawners is high. For Ireland as a whole the proportion of previous spawners ranges from 1 to 15 per cent, depending on the river and to some extent on the year, with an average of about 5 per cent. Most of the previous spawners have only a single spawning mark on their scales, a smaller proportion, about 3 per cent, have two; a few have three such marks on their scales. Fish with three spawning marks have only been identified on six occasions out of a total of nearly fifty thousand sets of Irish salmon scales examined to date.

Thus by using the scales a considerable amount of information has been compiled about the salmon of Irish rivers; but as Miss Twomey pointed out, other methods have to be employed to investigate other aspects of the life-history of Irish salmon.

Mr. E. D. Toner in his paper, "Movements of Salmon in the Sea around Ireland", then described the progress made in investigations in the open seas around Ireland since 1948 when the experiments were initiated. Live salmon taken in commercial nets were tagged with the Lea hydrostatic tag and released at several places around the Irish coast, namely: Baginbun, Co. Wexford (south-east coast); Rath, Co. Kerry (south-west coast); Achill, Co. Mayo (west coast); Streedagh, Co. Sligo (north-west coast); Portbraddan and Carrick-a-rede, Co. Antrim (north coast) and Carnlough, Co. Antrim (north-east coast). Altogether, 3,246 salmon and grilse were so tagged and 930 tags, or 28·6 per cent, were recovered. From Baginbun the predominant movement was westerly, but a small proportion of fish moved eastwards and then northwards, two proceeding long distances, one to the River Fane on the east coast of Ireland and one to the River Tay in Scotland more than eight hundred miles away. Movements from Rath were mainly to local rivers, but a few fish proceeded a hundred miles or more northwards up the west coast. Most of the recaptures from Achill were made in rivers within fifty miles of the tagging stations, though some fish made long journeys to places on the north coast of Ireland and west coast of Scotland. Individual fish went to Rhyl in North Wales and to the Conon River on the east coast of Scotland. Movements from Streedagh were mainly to local rivers. In the stations on the north coast of Ireland the predominant movement was westwards towards the River Foyle. A small proportion of fish, however, moved to the east coast of Ireland, to the west coast of Scotland and one even to the east coast of Scotland. From Carnlough on the north-east coast the movements were again predominantly towards the west, but there were substantial movements to the west coast of Scotland, and two fish travelled to the east coast of Scotland, one to the River Tweed.

As to the speeds of travel, the maximum apparent speed recorded was thirty-three miles a day, and only ten fish out of the eight hundred or so for which information was available reached their destinations after travelling at speeds of twenty miles a day or more.

Mr. Toner concluded that salmon approach the Irish coasts in a haphazard fashion, and only when they are close inshore do they make a definite search for the river of their origin.

Mr. Arthur Swain, in his paper "Factors affecting the Downstream Migration of Salmon and Sea Trout", pointed out that the 'departure stimulus' has always been associated with floods, but as long ago as 1926 H. O. Bull showed that this was not true, although Bull concluded that the initiation of the run of smolts was associated with rainfall.

For a number of years salmon and sea trout, smolts and kelts have been caught and tagged in the River Coquet at Warkworth in Northumberland at a specially constructed set of traps. Data relating to the downstream movement of the smolts and the temperature of the water, etc., were collected during 1952–57 inclusive. During these years many thousands of smolts were caught, a very high proportion in the hours of darkness, especially the first three or four hours. Few smolts were taken in March in the years 1953–56, when the temperatures were low, but in 1957 during that month a mild spell of weather resulted in a fairly large number of smolts being caught. As a rule, large numbers of smolts appeared from about the third week in April onwards, continuing well into May, and the numbers generally began to fall off at the end of May or early June.

Mr. Swain concluded that the migration of smolts was clearly seasonable, but within the migration season it appeared that the immediate stimulus for migration is either a rise in temperature, or some factor associated with a rise in temperature, acting on fish which have attained the proper physiological condition. The stimulus which causes the kelts to move downstream, on the other hand, is clearly associated with floods, and the rate of flow and turbidity of the water encouraged them to drift downstream. There is also some evidence that they are influenced by temperature and that a rise in temperature, as in the case of smolts, stimulates them to move downstream. A. E. J. WENT

IONIZATION PHENOMENA IN GASES

THE impressive history of rich contributions to the structure of contemporary physics presented by that branch concerned with the conduction of electricity in gases is well known. An indication of one reason why work in this field is at present in one of its more flourishing phases is contained in the name 'gaseous electronics'. This is a recent fashion which—though perhaps offensive to some—does recognize the extent to which the advances of the past decade or so have depended on developments in refined ultra-high-frequency and high-speed electronic instrumentation, very-high-vacuum and gas-handling techniques, stable high-voltage sources and so on. Moreover, the actual exploitation of improved technical facilities of this kind has been accelerated by several influences, notably the persisting need for more quantitative information on fundamental collision processes, not only in laboratory discharge-physics but also in fields such as ionospheric research and astrophysics, and also by the hope that studies of the extreme conditions which exist in heavily loaded plasmas may assist ultimate achievement of controlled nuclear fusion.

The present vigour of the field under review was amply demonstrated by the scope of the Third International Conference on Ionization Phenomena in Gases, arranged at Venice during June 11–15 by the Società Italiana di Fisica, under the presidency of Prof. G. Pulvani. This conference continued a series of biennial meetings initiated by A. von Engel at Oxford in 1953, followed by a meeting at Delft in 1955. A total of some forty papers was presented in the general sessions, and ninety in three parallel specialized sessions. It is thus obvious that the present review cannot do individual justice, since a mere catalogue of titles would consume much of the available space. This account is, therefore, restricted to details of general-session reports, with some remarks on special-session papers, principally in connexion with fundamental collision processes and spark breakdown, together with a broad coverage of papers on very high temperature plasmas, pulsed discharges, and plasma theory, since these topics received special emphasis owing to their relevance to thermonuclear reactions. This selection, however, leaves unnoticed many important contributions, particularly the numerous papers on glows, electrode actions, counter processes and technical applications.

After addresses of welcome by representatives of the several host organizations, the Conference opened with an invited paper by Prof. W. Lochte-Holtgreven (Kiel), on "The Emission of Spectral Lines from a Plasma". Characteristic of the well-known work of the Kiel school on heavily loaded arcs and other discharges has been the wide exploitation of spectroscopic methods. Prof. Lochte-Holtgreven compared current theoretical interpretations of spectral line-profiles with results of recent experimental work on lines of atomic hydrogen, helium I and helium II. There has been steady progress, during the past few years, towards better understanding of the relative contributions of plasma electrons and (slower) positive ions to the shapes of the emitted lines.

Prof. L. B. Loeb (Berkeley) was, unfortunately, prevented by illness from reading a second invited paper; the sympathy and greetings of the Conference were telegraphed to Prof. Loeb, whose substantial contributions to discharge physics are well known.

Atomic and Ionic Collision Processes

The general sessions opened with a paper by R. Varney (St. Louis) on "Ionization of Gases by Positive-ion Impact", in which, in continuance of earlier work, new results were reported on efficiencies and threshold energies of ionization by positive ions of alkali metals in various gases, obtained with apparatus of greatly improved sensitivity. J. Sayers (Birmingham) reviewed ionic reactions in gases, with special reference to work at Birmingham on electron recombination, in which—by a combination of Langmuir-probe and mass-spectrometer-probe techniques—the attempt is made to account for electron loss from an afterglow in terms of capture by the specific types of positive ion detected.

Important results on photo-ionization cross-sections of gases and photoelectric-yields of solids, investigated by improved vacuum-ultraviolet methods, have emerged from several laboratories in recent years. The work at Los Angeles described by G. L. Weissler included a number of new results, one point of particular interest being the high yields of photo-ionization found in several polyatomics—five to ten times those typical of simpler gases.

Some techniques of great elegance, including very sensitive optical-absorption methods, have been developed at Westinghouse Laboratories, Pittsburgh, for studies of concentrations and interactions of excited and particularly metastable atoms; some new results were reported by A. V. Phelps. Other experiments, also of great beauty, were described by L. M. Branscomb (Washington), in a paper entitled "Photodetachment Studies of Negative Ions". In this work, a mass-analysed beam of negative ions is intensely illuminated by light selected by an interference filter, the current of photo-detached electrons is measured, and cross-sections are derived. A related paper was that of V. Dukelsky (Moscow), on "Formation of Negative Ions and Atomic Structure"; the existence of negative ions of many elements was reported, the more stable forms often being molecular. An interesting problem is posed by the mechanism of formation of the ion He^- which, although of negative electron-affinity in its ground-state, has been shown by recent theoretical work to have a stable doubly-excited quartet state of long life-time.

Papers by R. L. F. Boyd and J. B. Hasted related to different aspects of the substantial programme of collision studies and discharge investigations at University College, London. Apart from a general review, the first of these described a method of performing electrically the (Druyvesteyn) analysis of probe curves, which gives greatly improved accuracy in determinations of the energy distribution among the plasma electrons. The second paper described apparatus for collision studies—especially of ionization by positive ions, with simultaneous check by mass-spectrometer of the fragmentation products in the processes of ionization and charge-exchange.

A valuable paper, presented by L. Goldstein (Urbana) on "Charge Interactions in Gaseous Discharge Plasmas", was concerned with experimental and theoretical results on the interaction processes which occur both within an electron-gas and between electrons and ions in a plasma. Experiments on the heat-propagation properties of plasmas were said to indicate that the electron/electron interaction, for which no satisfactory theory yet exists, is important even in plasmas of low ion density.

Spark Breakdown

The subject of the mechanisms of spark breakdown was introduced in reviews by J. M. Meek (Liverpool), "Recent Researches in Spark Breakdown", and H. Raether (Hamburg), "Townsend and Streamer Mechanisms". The first stage of breakdown in a gap occupied by a uniform field consists of a rapid growth of ionization by electron-impact, initiated by the acceleration of a single electron away from the cathode region (electron avalanche). The essential feature of the Townsend mechanism for building up the current in the gap lies in the development of fresh avalanches, in rapidly increasing numbers, as a result of the operation of one or more possible secondary processes, for example, emission of secondary electrons from the cathode due to bombardment by positive ions. Though such mechanisms have long been recognized as affording an adequate explanation of sparking phenomena for low values of the product (pressure × gap-length), until very recently severe difficulties existed at high values of that product. The streamer theory, associated with the names of Loeb, Meek, Raether, met such difficulties, at least qualitatively, by emphasizing the part played by photo-ionization of the gas and the distortion of the field produced by accumulated space-charges. However, an obviously unsatisfactory dichotomy persisted, with the employment of two widely differing theories for high and low values of the product (pressure × gap-length), leaving more or less untreated a large and ill-defined intermediate region. The most recent work has led to the belief that objections to Townsend mechanisms in spark gaps occupied by uniform fields near the critical sparking voltage have previously been over-estimated. While the subject is still very fluid, the vigour of current investigations encourages the hope that a comprehensive theory may be reached, possibly embodying a transition from 'Townsend' to 'streamer' breakdown with changing conditions.

Several other laboratories which have been active in this work were represented at the Conference. Thus, L. H. Fisher (New York), whose work on formative time-lags has been very significant, reported further results on pre-sparking phenomena in gases in uniform and non-uniform fields. F. Llewellyn-Jones (Swansea), describing some recent investigations on micro-arc discharges, dealt with breakdown mechanism and subsequent characteristics of a discharge such as that produced by the opening of an electrical contact; this work has obvious technical importance, and also faces difficulties from the small-scale nature of the phenomena. Other work at Swansea was described by C. Grey-Morgan, under the title "Electrode Ionization Phenomena in Gases". Detailed studies of the temporal relations of voltage, current and the intensity and propagation-velocity of the luminosity in over-volted impulse-sparks were reported by J. K. Theobald (Los Alamos).

The interpretation of the lightning-stroke—the extreme example of breakdown under conditions in which (pressure × gap-length) is large—is a continuing challenge to laboratory discharge physics; the value of new observational material, obtained by improved methods now available, was recognized from a paper by H. Norinder (Upsala) on "Some New Results on the Mechanism of Lightning Discharges".

In recent years much experimental and theoretical effort has been devoted to the breakdown processes in a gas subjected to an applied field at microwave frequencies. A laboratory which has been especially prominent in this respect is that of S. C. Brown (Cambridge, Mass.), who, under the title "Microwave Gas Discharge Breakdown in the Presence of Magnetic Fields", summarized the most recent results in this field.

Arcs and Glows

A number of general session papers were concerned with features of arc and glow discharges. D. J. Rose (Murray Hill), in a paper on secondary mechanisms of the glow discharge, described interesting results on the relative contributions of two processes of electron-ejection from molybdenum cathodes in hydrogen, deuterium, and neon, namely, ejection by incident positive ions and by photons. K. G. Emeleus (Belfast), in a paper with B. Love, gave an extended treatment of the complex of phenomena involved in the classification and stability of striations, and emphasized the likely value of detailed spectroscopic study of the several forms observed.

Three major papers on arc-discharges were read. In the first, H. Maecker (Erlangen), under the title "General Description of Electric Arcs and its Application to some d.c. Types", presented an amply illustrated review of the utilization of the electrical and spectral characteristics of several forms of arc channel, including uniform-cylindrical, free-burning (convection-stabilized), and high-current forms. In the second paper, on high-pressure discharges in gas mixtures, P. Schulz (Karlsruhe) discussed effects on field strength, light output and spectral distribution, in gas-arcs, in terms of relative excitation- and ionization-potentials and collision cross-sections, of the atoms of a binary gas mixture. In the third paper, on "The Anode-Drop in Low-Pressure Discharges and High-Current Arcs", K. H. Höcker (Stuttgart) distinguished the details of the processes of ion generation, supposed to be operative in the anode-region of these two discharge types.

An interesting paper by A. E. Robson (Oxford), on the evaporating cathode and the Tanberg effect, was concerned with the anomaly presented by simultaneous measurements of the evaporation-rate from the molten cathode of a metal arc, and the force of reaction produced on that electrode by the evaporating atoms; these measurements have previously led to estimates of the velocities of the latter, which correspond to improbably high values for the temperature at the cathode, around half a million degrees. The explanation now suggested for this so-called 'Tanberg effect' is that the number of evaporating atoms has been greatly under-estimated, by neglect of the fact that the majority—typically 95 per cent—of those leaving the surface are scattered back again by collisions in the cathode-layer.

Of the remaining papers on arc-discharges, space permits mention of only one, by H. Edels (Liverpool), on "Glow to Arc Transition in the Column and at the Cathode of a Hydrogen Discharge", describing experiments by both electrical and spectroscopic techniques, aimed at clarification of the complex processes involved in such transitional regions.

High Temperature Plasma and Pulsed Discharges

Contributions in this and allied sections showed that work in many laboratories is centred on the problems posed by the pinched discharge, in which constriction of a plasma column results from self-magnetic pressure. A. A. Ware (Aldermaston), one of the original workers in this field, described experiments with a toroidal discharge-tube. The ions and electrons are found to be pulled in rather slowly by the pinch-effect, with the development of a central region of high pressure, from which emerges a shock wave travelling outward. Within the shock-front the discharge passes in a narrow irregular channel. Similar irregular helical channels in toroidal discharges were reported by T. K. Allen (Harwell); during a long square current pulse (200 µsec., 4,000 amp.), rotation of the helix about the toroid-axis is indicated, at velocities 2–7 × 10^5 cm./sec., in argon and neon. P. Reynolds (Harwell) reported work with J. E. Allen, in which measurements of electron- and ion-temperature were made by several methods, using an apparatus similar to that of Ware; oscillatory currents of 15–20,000 amp. gave ion-temperatures of 5,000–40,000° K. A. N. Dellis (Harwell) described the use of microwave noise in the determination of plasma electron-temperatures; the noise at a wave-length of 8·5 mm. from a hydrogen discharge yielded electron-temperatures up to 2 × 10^5 °K.

A highlight of the Conference was the report of S. A. Colgate, of work on pinched discharges in deuterium, by a group at Livermore in the United States. These important investigations were made some years ago but have, unfortunately, remained classified until recently. As in the case of similar work done in the U.S.S.R., and reported by I. Kurchatov at Harwell in 1956, copious bursts of neutrons were obtained, which, however, are not likely to have been of true thermonuclear origin. The most significant results of the Livermore experiments leading to the latter conclusion are: (*a*) the neutrons arise in the gas, uniformly along the discharge-axis, where the temperature should be highest, (*b*) application of a small axial magnetic field quenches the production of neutrons, (*c*) the deuterons colliding to produce neutrons, by the reaction ${}^2D_1 + {}^2D_1 \rightarrow {}^3He_2 + {}^1n_0$, have axial velocities corresponding to energies of 200–300 kV. The suggested mechanism for the production of neutrons is that the pinched discharge becomes unstable, the uniform column splitting into 'droplets' along the axis of the tube, possibly leading to high axial electric fields in which the deuterium ions are accelerated. Quenching of the yield of neutrons by the small magnetic field is then attributed to the effect of the field in limiting the axial instability.

R. F. Post (Livermore), in a paper on problems of research into controlled fusion, amplified and revised the useful appreciation he contributed to "Reviews of Modern Physics" in 1956. The results of his latest work were given in the form of new limits for temperature, density, size and magnetic field. The need for great purity of the reacting gases was emphasized.

The production and study of heavy-current discharges were described by C. Breton *et al.* (Saclay). The apparatus used consisted of a torus, similar to those used at Aldermaston and Harwell, in which a high gradient of electric field could be induced by an oscillatory condenser discharge. The occurrence of shock-waves was demonstrated, and pulses of γ-rays of 150-kV. energy were detected. The spectroscopy of the discharges was discussed in a companion paper.

R. J. Bickerton (Harwell) described theoretical and experimental work on the effect of a stabilizing magnetic field on a toroidal discharge. Theoretically, limited regions of current and magnetic field are expected, over which the discharge should be stable, without the pinch-effect being seriously modified by the applied magnetic field. Experimental tests, using pulsed currents and fields, more or less support the theory, and ionic- and electron-temperatures of order 500,000° K. have been estimated.

Later in the Conference, three further papers on condenser discharge work were presented. The first was by K. Siegbahn (Upsala), who reported detection of neutrons in a 60-µF., 50-kV. discharge in deuterium. The other two papers, by S. Curran and K. W. Allen, related to work at Aldermaston, employing a circular arrangement of 144 condensers, connected by short leads to a centrally placed discharge-tube. Novel features, however, were the use of a separate triggered gap on each of the condensers used, and the application of a pre-ionizing pulse to the gas in the discharge tube. Pulses of up to 10^5 neutrons were obtained, and it may well be that the mechanism of production of these was different from that suggested by Colgate, since the yield of neutrons was found to be much less sensitive to concentration of nitrogen impurity and to an axial magnetic field. A paper by P. C. Thonemann and A. Gibson (Harwell) discussed the production of run-away electrons in toroidal discharges. With a stabilizing axial magnetic field of 1,000 gauss, such electrons were detected by the X-rays they produced; the energy of the electrons was estimated to be 25–30 kV., and the yield approximately one-sixth of that expected from elementary theory. H. Dreicer (Los Alamos) also discussed the run-away electron phenomena from a theoretical point of view.

M. O'Day (Cambridge, Mass.) reported work with W. G. Chace and E. W. Cullington on the explosion of wires by discharges from heavy condensers. Instrumentation, under the conditions of extreme interference which necessarily exist, presents much difficulty, and the equipment installed is probably as advanced, as regards design and screening, as any yet devised. An impedance match was achieved between the bank of condensers and the wire specimen. No pinch-effects had been observed in either solid or vapour, but it was hoped that these would be found on further increasing the rate of increase of current.

Plasma Theory

The papers presented on plasma theory covered an extremely wide field, extending from studies of distribution functions, to calculations concerning the stabilities of particular discharges. In the first session, M. Delcroix (Paris) discussed the work of a group at the École Normale Supérieure, leading to an expression of the velocity distribution function in a lightly ionized gas as a series of eigenfunctions of the collision operator. H. Schirmer (Berlin) gave a detailed account of the calculation of the electrical conductivity of a partially ionized gas, with special reference to a high-pressure xenon discharge, which was used to check the calculations. R. Jancel and T. Kahan (Paris) discussed, in two papers, the distribution function for a partially ionized gas subjected to oscillating electric and steady magnetic fields, and also the problems of wave-propagation in such a plasma. G. Schmitz (Aachen) gave an account of a method of solving the energy-balance equation for a cylindrical plasma channel, in which the thermal and electrical conductivities are known functions of temperature.

The second session, which was mainly concerned with the fundamentals of plasma stability, was opened by M. Kruskal (Princeton), well known for his pioneer work with Schwarzschild on the stability of a pinched discharge. Two papers were presented, both concerned with invariants of motion in ionized gases. The first dealt with the spiralling of charged particles of small ratio (ϵ) of mass to charge. An adiabatic invariant, which has been discussed by H. Alfvén, for the case $\epsilon = 0$, was generalized to all powers of ϵ. The second paper, with I. Bernstein, E. Frieman and R. Kulsrud, gave an energy principle for examining the stability of a discharge channel of more general application than the customary 'normal-mode' approach.

The group at Göttingen, L. Biermann, K. Hain, R. Lüst and A. Schlüter, also reported a detailed study of the problems of hydromagnetic stability. In addition, a novel method of heating a plasma was proposed, in which an isolated mass of ionized gas is subjected to a cyclically varying magnetic field. Arguments based on equipartition of energy show that the temperature of the plasma is thereby raised.

A paper by M. Rosenbluth (San Diego) was one of several theoretical studies concerned with the stability of the pinched discharge, one of which has been mentioned earlier. Rosenbluth treated the problem of a cylindrical discharge with axial magnetic field and conducting boundary, and gave conditions for stable operation. H. L. Jordan (Aachen) also discussed the stability of pinched discharges.

In the final session, the same topic was treated by R. J. Tayler (Harwell), who gave the results of 'normal mode' calculations of stability in pinched discharges. For a system in which the current is confined to the surface of a cylindrical column of gas, he showed that no stability is possible for the first-order 'mode' for any external magnetic field if the discharge tube has an insulating wall. With a conducting boundary of not too great a radius, image forces can remove the residual instability, so that complete stability is possible. For the more general case of a volume distribution of current the situation is complex, but complete stability is not very likely.

W. B. Thompson (Harwell) considered the transition between low-current discharges controlled by diffusion and the high-current pinched discharge. H. Margenau (New Haven) presented a paper on the conductivity of plasmas with respect to microwaves in which the distribution function was assumed to have one of several simple forms and was perturbed only slightly by the microwave field. He also reported work with D. C. Kelly on power absorption from microwaves at the cyclotron resonance by electrons of low energy in a discharge. From the half-width of the resonance curve the collision frequency could be deduced.

Two papers were presented by J. G. Linhart (Geneva) and D. C. de Packh (Washington) on the problems arising in the production of electron beams with neutralized space-charges first discussed by Bennett[1] and Budker[2]. In the first paper by Linhart the theory of the production of such beams was considered. In the second, read by A. C. Kolb, the possibility of additional focusing of electrons by external magnetic fields was taken into account, leading to a reduction in the stabilizing proton-core and to conditions which are rather easier to realize in practice.

Two general addresses remain to be mentioned. These were by Prof. V. Gori (Rome) and Dr. A. von Engel (Oxford), and took the form of tributes to the life and work of the late Prof. Giorgio Valle.

The success of the Venice meeting lay largely in the presentation, in many of the papers, of much really new material and in the evidence thus provided of intense activity on a wide front. The next conference of the series is to be held in Upsala in 1959.

DUTCH–NORWEGIAN JOINT ESTABLISHMENT FOR NUCLEAR ENERGY RESEARCH

REPORT FOR 1955–56

THE Joint Establishment for Nuclear Energy Research (J.E.N.E.R.), situated near Oslo and operated jointly by the Norwegian Institutt for Atomenergi (IFA) and the Dutch Stichting Reactor Centrum Nederland (RCN) through a commission consisting of three Dutch and three Norwegian members, has recently issued its fifth annual report*, covering the period from July 1, 1955, to June 30, 1956.

The natural-uranium reactor, JEEP, which is moderated and cooled with heavy water and has now been in operation for nearly five years, is the main piece of research equipment at the Establishment. Its total energy release during the period under review was about 70 MW.-days, compared with 50 MW.-days for 1954–55. The reactor had a major shut-down during February 26–March 12, 1956, for the installation of a new heat-exchanger, the final stage in the introduction of a new cooling system. This heat-exchanger, which transfers the heat from heavy to ordinary water, has five times the surface area of the old exchanger, and the ordinary water is circulated from it through a cascade-type cooling tower to a reserve tank. With the new cooling system the reactor may be operated at a much higher power-level than previously, and, in addition, the operation is entirely independent of the prevailing weather conditions. The fuel elements were inspected twice, during August 1955 and March 1956, and the inside of the reactor tank once, during August 1955; their conditions were found to be satisfactory and no replacements were made.

During the year the number of shipments of radioisotopes from the Establishment totalled 614, only a small increase on the previous year's total of 579. The shipments were mainly to Norway, Sweden, Denmark and Holland. An additional 204 irradiations were made for use within the Establishment. Although the demand for radioisotopes is steadily increasing, no increase in production can be expected until the completion of the construction of the new buildings, for which plans have already been made. The report includes a list of the various isotopes produced, the number of shipments and their destinations, and the main fields of application.

New research equipment has been installed in both the metallurgy and physics laboratories, where a wide range of experimental work is being carried out. For casting uranium, a high-frequency (450 kc./s.) induction high-vacuum furnace supplying 22 kW. has been constructed, and metal specimens weighing 1–2 kgm. can now be melted and cast under a pressure of about 2×10^{-7} mm. of mercury. Since uranium exhibits dimensional instability, both on thermal cycling and under irradiation, a thermal cycling furnace has been built for the study of the behaviour of the metal under cycling conditions. The instability is known to be dependent upon the degree and type of preferred orientation, and a series of dilatometric experiments on preferred orientation in uranium containing 0·25 per cent chromium has been carried out. Additions to the equipment used for neutron diffraction work and for crystal structure studies included a Philips X-ray diffraction unit, a Geiger-counter diffractometer and several X-ray cameras, and studies have been made of hexamethylenetetramine, pentaerythritol, calcium hypophosphite, and mercury oxide. Other experiments conducted in the Physics Division have been concerned with the circular polarization of capture gamma-rays, and the gamma-rays emitted by fission fragments. The series of photo-nuclear reaction studies at Det Norske Radiumhospital using the betatron has been continued.

---

* Fifth Annual Report, July 1955–June 1956, of the Dutch–Norwegian Joint Establishment for Nuclear Energy Research. Pp. iv+32. (Lillestrøm. Joint Establishment for Nuclear Energy Research, 1957.)

In the Chemistry Division, in addition to routine chemical and spectrographical analyses, the recovery of caesium-137 from fission products by co-precipitation with ammonium aluminium sulphate is being investigated. The study of the chemistry of plutonium has continued, and a sixty-four channel pulse height analyser, constructed in the electronics workshop, is now being used for routine analysis of uranium and plutonium mixtures.

During the second half of the year most of the work at the Establishment was concerned directly or indirectly with the Halden boiling-water reactor project, which was referred to in the report for 1954–55 (see *Nature*, 178, 1220; 1956). In 1956 the project received the official approval of the Norwegian Parliament, and the work is now well advanced. The reactor will be financed and built under the auspices of the Institutt for Atomenergi, but the design and planning are to be carried out by the Establishment. Many of the mechanical components will be produced by Norwegian firms, and negotiations are stated to be in progress with the United Kingdom Atomic Energy Authority and with the United States Government for the supply of the uranium fuel and heavy water, respectively. The reactor will be fuelled by seven tons of uranium distributed in a hexagonal lattice with a maximum of 325 fuel elements. The amount of heavy water needed as moderator and coolant is 15 tons. Initially, ten cadmium control stations will be installed, but the design allows for an additional nine if required. Although the plant will eventually supply process steam to a nearby paper mill, this is merely intended as an inexpensive way of dissipating the liberated energy, and the plant should really be regarded as an experimental engineering plant with a high degree of flexibility in design, permitting considerable variation in many of the basic specifications. The detailed discussion of the Halden project in the annual report includes a simplified schematic diagram of the reactor and associated equipment.

In the final sections of the report details are given of the various reports and publications issued by the Establishment during the period under review; of the reactor courses given at the Establishment; of personnel and accounts; of the numerous scientific meetings and conferences at which the Establishment was represented; and of the thirty-seven guest scientists representing twelve different nations who worked at the Establishment during part or the whole of the period covered by the annual report.

THE BRISTOL MUSEUM

REPORT FOR 1956

THE annual report* of the City of Bristol Museum is, as one has come over the years to expect, a well-produced, readable and stimulating publication reflecting the activities of one of Britain's outstanding provincial museums. Putting first things first, it deals with the personnel of committee and staff, with changes of persons and of posts, with new recruits and with degrees awarded, winding up with a gracious recognition of long services rendered—retirements after 22, 22 and 26 years—a loyalty accorded and therefore clearly inspired. A novel post filled during the year is that of assistant curator in conservation, which called naturally for accommodation and equipment, a special laboratory and an iron treatment room. This is surely a realization of the best and most up-to-date in the museum tradition reflected in Dr. H. J. Plenderleith's recently published and remarkable text-book (see *Nature*, 179, 280; 1957).

In another field Bristol Museum continues to lead, namely, in its public education services, which achieve great things, not only among adults and schoolchildren of the area, both in classes and in leisure-time societies and clubs, but also among museum men and educationists from elsewhere, who seek practical experience and inspiration to transplant to their own institutions. Work continues on the permanent exhibits, inevitably calling for improvement and re-identification as research adds to the general field of knowledge, and the fact that half the report is devoted to a list of accessions indicates both the lively outlook of the director and curators of Departments and the appeal the Museum exerts upon its supporters.

Temporary exhibitions, which do so much to enliven and attract, numbered no less than fifteen. Among the special features which have been continued with increasing success is the 'exhibit of the month', to which the city archivist has added quarterly exhibitions of Bristol playbills, concert notices, news-sheets of royal visits and so on, while the city librarian has provided material dealing with a local figure, the boy-poet Chatterton. The Museum finds a ready demand for its *Quarterly Bulletin* and for leaflets describing summer walks—which have an embarrassing success—and winter lectures. The list of conferences, together with their home ports, is a most impressive one. Yet, with all these varied offerings to a public seven days each week, the staff has time to serve on a wide range of local and national committees and to conduct research and to publish the results in scientific and learned periodicals of standing. This is a full report betokening, on the part of all concerned, a full and doubtless satisfying life.

DEFENCE MECHANISM OF PLANTS AGAINST FUNGI

Fungistatic Properties of Apple Leaf Wax

MANY workers have reported the occurrence in plants of antifungal agents which may contribute towards the natural ability of the plants to resist infection by fungi. Gilliver[1] found that macerates of many plants could inhibit spore germination, while Topps and Wain[2] have recently substantiated the early findings of Brown that the intact leaves of some species of plants yield small quantities of water-soluble compounds possessing fungitoxic properties. Spencer, Topps and Wain[3] have also detected the presence, in exudates of the stem and root of *Vicia faba*, of an antifungal substance, phenolic in character, which, they suggest, is produced in response to a wounding stimulus. Buxton[4] has shown that some pea root exudates are active against *Fusarium oxysporum*, and Turner[5] has reported that the sap of seedling oat leaves contains an inhibitor of *Ophiobolus graminis*. Protocatechuic acid has been linked with the resistance to disease of onion varieties[6], while Virtanen and his co-workers[7] have isolated a fungitoxic compound, 2(3)-benzoxazoline, from cereal seedlings. Reports have also been made of the association of chlorogenic acid and phenolics with the disease resistance of varieties of potato, wheat and linseed.

The natural defensive mechanism of apple leaves and fruits has also received attention. Zschokke, as early as 1897, considered that any resistance of apple fruits to fungus infection was due to chemical substances and not to mechanical protection afforded by the cuticle. Later, Wiltshire and Johnstone reported from Long Ashton a correlation between the resistance of apple leaves and the toxicity of expressed sap to scab spores. Kirkham and Flood[8] at East Malling have recently shown that compounds of the chlorogenic acid type are involved in the natural protection of apple shoots from scab.

We have examined the leaf wax of apple and other species, since this may be expected to form the first barrier to infection. The waxy material was obtained by washing leaves with ether at room temperature. On extraction of the ether solutions with dilute alkali (1 per cent potassium hydroxide or 1 per cent sodium bicarbonate followed by 1 per cent potassium hydroxide solution) appreciable quantities of acidic materials were obtained. These were then separated into fractions preferentially soluble in ether ('ether-soluble acids') or water ('water-soluble acids'). The remaining waxy material was steam-distilled to give the volatile, non-acidic constituents, and the residual resin was fractionated by the addition of acetone to a concentrated ether solution to obtain the 'true wax' (acetone-insoluble) and 'oil' (acetone-soluble) components (see Table 1).

The apple leaf waxes and their constituents were examined for their ability to inhibit the germination of the conidia of mildew (*Podosphaera leucotricha*). Healthy detached leaves of the mildew-susceptible *MM* 104 apple rootstock were lightly sprayed with an ether solution, or dipped in a water solution, containing 0·075 per cent of the material under test. Provided the leaves were not too young, no damage resulted from the ether treatment; the amount of material deposited was of the order of 40 μgm./sq. cm. A small amount of wetter was added to the aqueous solutions to ensure adequate wetting of the leaves; the amount of acidic material left on the leaf tissue after drying was judged to be about 6–8 μgm./sq. cm. The leaves were then dusted with mildew conidia taken from infected rootstocks or orchard trees and, with their petioles immersed in water, were incubated for 48 hr. at 20° C. and relative humidity about 80 per cent. The spores were recovered from the leaves on cellulose acetate films[9], stained with 1 per cent aqueous safranin and examined for percentage germination (see Table 2).

W, Worcester Pearmain; *C*, Cox's Orange Pippin; * not determined

The outstanding feature of the analytical results is the high proportion in the leaf waxes of materials extractable by dilute alkali. The ether-soluble acids obtained from the Worcester and Cox leaves collected in 1956 were subjected by Dr. C. G. Whiting to paper chromatography using a benzyl alcohol–isopropyl alcohol–tertiary butyl alcohol–formic acid–water mixture. The main acidic spot ($R_F = 0·82$) showed some fluorescence which was rather stronger with

ammonia and gave positive reactions with the following reagents: ferric chloride (reddish-purple, brown on exposure to ammonia), ferric chloride–potassium ferricyanide (strong blue colour), alkaline potassium permanganate (yellow colour), diazotized *p*-nitraniline (strong reaction, orange) and ammoniacal silver nitrate (reduced). These properties are very similar to those of the phenolic compound detected in exudates of *Vicia faba* by Spencer, Topps and Wain.

Elution of the Cox ether-soluble acids from a silica gel column with chloroform and chloroform–tertiary butyl alcohol mixtures gave two main components: a phenolic material and a strongly acidic substance which gave a bright blue fluorescence with ammonia, reduced silver nitrate weakly and gave no reaction with diazotized *p*-nitraniline. A small amount of the acidic material was recovered in crystalline form melting at 123–127° C.

Measurements of leaf surface area permitted an assessment to be made of the intensity of wax formation on the leaves. Young leaves showed about 50 μgm. of waxy material per sq. cm., with an indication of a heavier deposition on the Worcester than on the Cox leaves. Later in the season lower fluctuating values were obtained.

The biological results show that the Worcester and Cox leaf waxes, and some of their fractions, when sprayed on to mildew-susceptible leaves bring about a reduction in the germination of apple mildew conidia. The most striking fungistatic effect is shown by the ether-soluble acidic material extracted from the leaf waxes by dilute potash. The toxicity of this fraction was also shown in tests with *Botrytis fabae*; deposits of the acids on broad bean leaves entirely suppressed the formation of fungus lesions.

It seems reasonable to suppose that the ether-soluble acidic fraction, which occurs in high proportion (about 40 per cent) in the wax, plays some part in the defensive mechanism of the apple leaf. The water-soluble acidic fraction, which is probably an exudate from within the leaf, may also contribute to the fungistatic property of the wax. Fractionations of the leaf waxes of broad bean, dwarf bean, pea, tomato, pear, cabbage, laurel and grass and of the fruit waxes of apple, tomato and gooseberry have shown that these also contain appreciable, although varying, quantities of ether-soluble acidic materials.

Solubilization of Copper by Leaves and Water-soluble Acids from Leaf Wax

Barker and Gimingham[1] in 1911 put forward three possible mechanisms of the fungicidal action of Bordeaux mixture on plant surfaces. One postulated that solubilization of copper was effected by secretions of the fungus, and another, that the host plant itself played a part in the liberation of copper from the insoluble spray deposit. These possibilities were examined by later workers, notably McCallan and Wilcoxon[2] and Wain and Wilkinson[3], and the theory involving the action of secretions of the fungus received support. In their examination of the effect of the host plant, Wain and Wilkinson found that runner bean leaves released copper from Bordeaux mixture, but they considered their experiments suspect because of interference from exuded sap and bacterial contamination. Curtis[4] has shown that the guttation fluids of plants solubilize copper from Bordeaux mixture, while Yarwood[5] has concluded that the plant may enhance the effectiveness of this fungicide.

Table 1. COPPER DISSOLVED FROM BORDEAUX AND BURGUNDY DEPOSITS BY LEAVES

Leaf	Copper dissolved p.p.m.	
	Bordeaux	Burgundy

Potato	1·9	5·7, 6·2, 3·7, 5·7
Tomato	—	1·8
Control, deposits on glass	0·12–0·14	0·24–0·36

We have determined the solubilization of copper from dry deposits of 10 : 12·5 : 100 Bordeaux mixture and 10 : 11·4 : 100 Burgundy mixture on different leaves. The upper surfaces of healthy, uninjured leaves of area 10–20 sq. cm. were sprayed with the fungicides to the point of run-off and allowed to dry overnight. The leaves were then detached and their petioles immersed in paraffin wax to prevent sap exudation and to maintain leaf turgidity. Each leaf was placed in a Petri dish, weighted with a glass triangle, 30 ml. of glass-distilled water were added, and the dish was gently agitated for 17 hr. at 25° C. The liquid was centrifuged to remove any solids in suspension and its copper content determined[6] (see Table 1).

Other tests were made using the water-soluble acids separated from leaf waxes as described in the previous section. Burgundy mixture was sprayed on to Petri dishes and allowed to dry. Water solutions of the acids (concentrations 0·02–0·10 per cent: *p*H 4·3–3·4) were added and the dishes were agitated as before. The liquids were recovered free from suspended matter and analysed for copper content (see Table 2).

An excess of insoluble fungicide was present at the end of each test, and on no occasion did bacterial contamination occur. On some occasions minor leaf damage resulted in abnormally high values for dissolved copper and these are not reported. Comparable tests with the leaves and water-soluble acids showed that only slight solubilization of copper occurred from deposits of cupric oxide. No solubil-

Table 2. COPPER DISSOLVED FROM BURGUNDY DEPOSIT BY WATER-SOLUBLE ACIDS SEPARATED FROM LEAF WAXES

Water-soluble acids	Copper dissolved p.p.m.
Cox apple wax, potash extraction	5·5, 4·1, 3·8, 4·2
Worcester apple wax, potash extraction	5·6, 10·5, 2·8, 3·3
Worcester apple wax, bicarbonate extraction	10·2
Laurel wax, potash extraction	9·1
Control, water alone	0·3

izing effect was obtained in tests using the ether-soluble acidic fraction of apple or laurel leaf wax.

The results show that leaves and the water-soluble acids associated with leaf waxes are capable of solubilizing copper from Bordeaux or Burgundy spray deposits. These fungicides exert their toxic effect by virtue of the liberation of copper in solution. Although solubilization of copper is known to result from the action of spore suspensions containing a million or so spores per ml., it is difficult to believe that the exudates of spores occurring naturally on leaf surfaces can exert a significant effect. The conclusion is reached that the host plant, through the influence of acidic material associated with its wax, plays the primary part in bringing about the fungitoxic action of Bordeaux or Burgundy mixture.

Sorption of Copper from Burgundy Mixture by Leaves

Large *et al.*[1] found that when Bordeaux mixture deposits had been present on potato leaves for three weeks a significant amount of copper was retained by the leaves after exhaustive acid washing, although no sorption could be detected from fresh deposits. Smith *et al.*[2] and Hammar[3] have also shown that part of a copper spray deposit is not removed by acid washing. This matter has been re-examined, since a significant degree of sorption of copper by leaves may reduce the fungitoxicity of the spray deposit.

Burgundy mixtures (prepared from equimolar solutions of copper sulphate and sodium carbonate) of 0·25 and 1·25 per cent copper content were placed in 5-μl. droplets, each containing 8–10 or 40–50 μgm. copper, on the under surface of broad bean leaves. When the deposits had dried the leaves were removed from the plant and immersed, with gentle agitation, in 3 *N* hydrochloric acid for 0·5, 1 or 2 min. and in 0·1 *N* hydrochloric acid for 1, 2 or 5 min. The leaves were then well washed with water before acid digestion and copper analysis[4].

The copper remaining on the leaf after these washing processes amounted to approximately 0·03 μgm. per droplet and was uninfluenced by the period the deposit had remained on the leaf (up to 3 weeks) or by the concentration of Burgundy mixture used. The copper sorbed from total deposits of 150–200 and 750–1,000 μgm. copper per leaf was less than the naturally occurring copper present in the leaf.

Table 1. Copper sorbed from Burgundy Mixture by Broad Bean Leaves

Leaf surface	Washing procedure	μgm. Copper sorbed/droplet
Upper	0·1 *N* hydrochloric acid, 1 min.	0·16
	0·1 *N* hydrochloric acid, 5 min.	0·10
Under	3 *N* hydrochloric acid, 30 sec	0·03, 0·02, 0·02, 0·05
Under	0·1 *N* hydrochloric acid, 1 min.	0·07, 0·08, 0·09

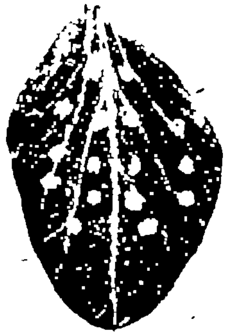

Fig. 1. Under surface of broad bean leaf showing inhibition of *B. fabae* lesions by Burgundy mixture (0·00012 per cent copper) (0·006 ± 0·002 μgm. copper/droplet)

A confirmatory experiment was carried out using copper-64. Irradiated copper foil was dissolved in sulphuric acid, the sulphate was precipitated in alcohol, dissolved in water and added to equimolar sodium carbonate to give a copper concentration of 0·25 per cent. Droplets of 5 μl., each containing 8–10 μgm. copper, were applied to bean leaves. The copper sorbed after the dried deposit had been on the leaf for 4 hr. was determined by radio-assay of acid digests (see Table 1).

The results confirm the values obtained by chemical analysis; the small amount of copper sorbed resisted the action of 3 *N* hydrochloric acid. An equivalent Burgundy deposit on glass was completely removed in 20 sec. by 0·1 *N* hydrochloric acid. Autoradiographs of the acid-washed leaves showed spots of the same size as the applied deposits, indicating that copper was not redistributed on the leaf by the acid washing. The upper surface of the leaf showed a similar capacity for sorption of copper.

To determine whether the sorbed copper was fungicidally active, a modification[5] of Morgan's bioassay technique[6] was used. Spores of *Botrytis fabae* Sardiña were dusted on to the under surface of bean leaves;

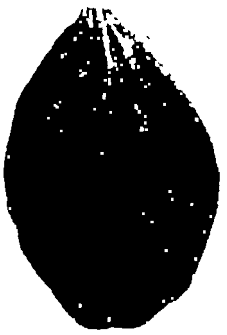

Fig. 2. Under surface of broad bean leaf. Deposits of Burgundy mixture (0·25 per cent copper) washed off with 3 *N* hydrochloric acid for 30 sec.—no inhibition of lesion formation. (0·02 μgm. copper/droplet remaining)

the spore density on the leaf was 500–1,500 spores/sq. mm. After incubation in a water-saturated atmosphere at 21° C. for 16 hr. the surface of the leaf was completely covered by lesions. On treating leaves with 5-µl. droplets of Burgundy mixture (0·25 per cent copper), lesion-free areas, of dimensions identical with those of the deposits, were produced. The most dilute Burgundy mixture (0·00012 per cent copper) that would inhibit lesion formation contained 0·006 ± 0·002 µgm. copper per 5 µl. droplet (Fig. 1).

Leaves that had been treated with Burgundy mixture and acid washed as described above were also subjected to the fungus infection test. Without exception, lesions formed over the whole leaf surface (Fig. 2). No fungitoxic action of the sorbed copper could be detected although it was present on the leaf in amounts up to fifteen times greater than the minimum giving a response in the bioassay test.

The results show that a small, but significant, amount of copper is sorbed from a Burgundy deposit by bean leaves and that this copper is fungicidally inactive. The experimental evidence suggests that the copper is adsorbed on the surface rather than absorbed into the leaf and that the sorption occurs while the fungicide deposit is drying.

We are indebted to Mr. C. P. Lloyd-Jones for carrying out the radioassays and to Mr. N. G. Morgan for advice on the bioassay technique.

ADDITIONAL PURINE COMPOUNDS IN THE VENOM OF THE TIGER SNAKE (*NOTECHIS SCUTATUS*)

By HAZEL M. DOERY

Commonwealth Serum Laboratories, Parkville, N.2, Victoria, Australia

FISCHER and Dorfel[1], and Doery[2], have identified adenosine, adenosine 3′-phosphate and a guanine compound in snake venoms. In this communication, which supplements the earlier report[2], the guanine compound and two additional purines are identified in the venom of *Notechis scutatus* as guanosine, inosine and hypoxanthine, respectively.

The preparation of the venom and the paper chromatography techniques in use were the same as those described earlier. In the course of some chemical fractionations of the venom of *Notechis scutatus*, an ultra-filtrate of the aqueous solution of the venom was prepared, using a membrane similar to that described by Wilson and Holiday[3]. The ultra-filtrate was dialysed against distilled water and the dialysate dried from the frozen state. Solutions of ultra-filtrate dialysate were applied to Whatman No. 1 filter paper and run in *n*-butanol–water for 16–60 hr. at room temperature (20–24° C.). Purine spots were eluted with distilled water, dried from the frozen state and aliquots treated as follows: (*a*) portions were chromatographed as above; (*b*) further portions, dissolved in 0·2 *N* hydrochloric acid and 1 *N* sodium hydroxide, were examined in a Unicam spectrophotometer between 220 and 300 mµ (Table 1); (*c*) the remaining portions were hydrolysed in 1 *N* hydrochloric acid at 100° C. for 1 hr., and the products dried. The hydrolysed eluates were examined both chromatographically in *n*-butanol–water or isopropanol–hydrochloric acid, and in the spectrophotometer as above (Table 1). Nucleic acid hydrolysed in 1 *N* hydrochloric acid for 1 hr. at 100° C. provided markers for adenine and guanine.

By longer development in *n*-butanol–water, two zones, each of which was previously considered to be homogeneous, are now shown to be composite.

The five purine compounds are identified in ultra-filtrate dialysate (Fig. 1) in order from the origin as: (1) adenosine 3′-phosphate; (2) guanosine; (3) inosine; (4) adenosine; (5) hypoxanthine; (2) and (3) being resolved completely only after 60-hr. development. Chromatography of the hydrolysates of the eluted compounds (1), (2) and (4) (Fig. 2) identifies the base of compounds (1) and (4) as adenine and (2) as guanine, supporting the conclusion that compounds (1), (2) and (4) are adenosine 3′-phosphate, guanosine and adenosine, respectively. Finally, the hydrolysate of eluted compound (3) and the eluate of compound (5), both before and after hydrolysis, have the same R_F value as hypoxanthine (Fig. 3), which confirms the identity of compounds (3) and (5) as inosine and hypoxanthine, respectively.

The absorption data on eluates from chromatograms (Table 1) further support the identification of guanosine, inosine and hypoxanthine.

The ultra-filtrate dialysate, a protein-free source of all the purine compounds in the venom, provided a concentration of those compounds 2–10 times that found in the previous fractions[2], and was more readily available for the present study. In the earlier investigation[2], three purine compounds were separated with the solvent *n*-butanol–water, and

Table 1. WAVE-LENGTHS OF MAXIMUM AND MINIMUM ABSORPTION OF ELUATES

Inosine hydrolysed	0·2 *N* HCl 1·0 *N* NaOH	249 263	216·5 235
Hypoxanthine hydrolysed	0·2 *N* HCl 1·0 *N* NaOH	246·5 262·5	215 233·5

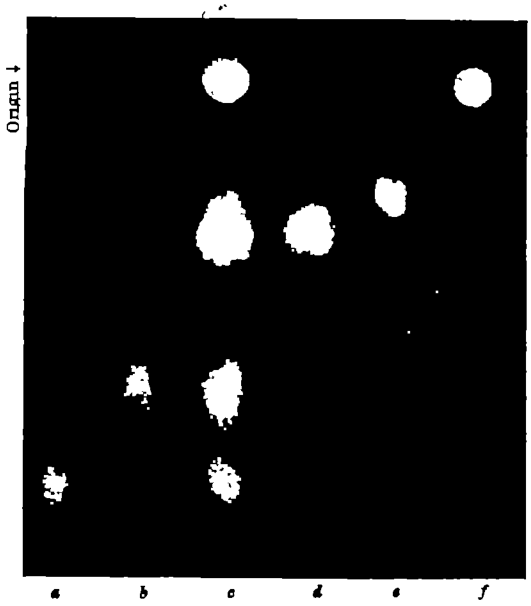

Fig. 1. Solvent: 86 per cent (v/v) aq. *n*-butanol (ref. 4); descending (*a*) hypoxanthine; (*b*) adenosine; (*c*) ultra-filtrate dialysate; (*d*) inosine; (*e*) guanosine; (*f*) adenosine 3′-phosphate

identified by appropriate markers by characteristic fluorescence and absorption maxima as adenosine, adenosine 3′-phosphate and a guanine compound. Protein material remained at the origin together with adenosine 3′-phosphate. Further, using the solvent sodium dihydrogen phosphate–isoamyl alcohol, three purine compounds were separated from protein material, and two of these were identified as adenosine and adenosine 3′-phosphate. When an eluate of the third compound showed an absorption maximum near 249 mμ, it was assumed to be the guanine compound. This has now been identified as inosine, which alone of the five compounds moves as a single component in sodium dihydrogen phosphate–isoamyl alcohol. The zones of adenosine and hypoxanthine overlap, as do those of adenosine 3′-phosphate and guanosine. Thus, the unsuitability of sodium dihydrogen phosphate–isoamyl alcohol as a solvent for the separation of the five compounds, which are completely resolved by longer development in *n*-butanol–water, is now evident.

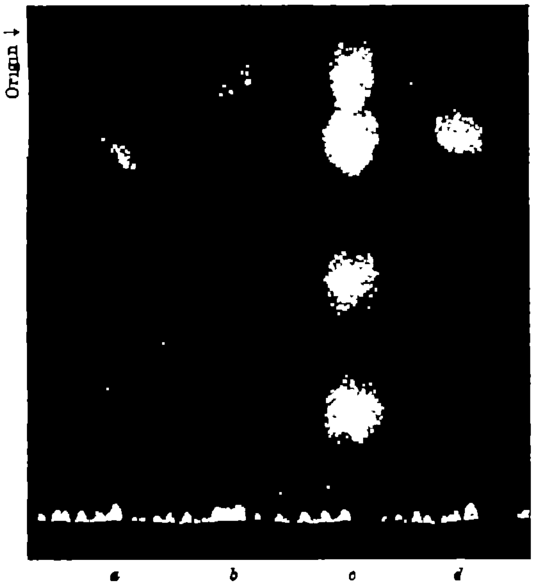

Fig. 2. Solvent: isopropanol (65 per cent v/v)–water–hydrochloric acid 2.0N (ref. 5): ascending. (*a*)–(*d*) hydrolysates of (*a*) eluate compound (4); (*b*) eluate compound (2); (*c*) nucleic acid; (*d*) eluate compound (1)

Subsequent to the above examination, an extract of the venom of eight tiger snakes 'milked' directly into 3 per cent perchloric acid was examined. The supernatant and washings from the resulting protein precipitate were neutralized with 2 *N* potassium hydroxide, and the insoluble potassium perchlorate removed by centrifuging. The supernatant was dried from the frozen state and chromatographed in *n*-butanol-water. Adenosine, adenosine 3′-phosphate and guanosine were clearly identified, a slight trace only of inosine was detected, while hypoxanthine was absent.

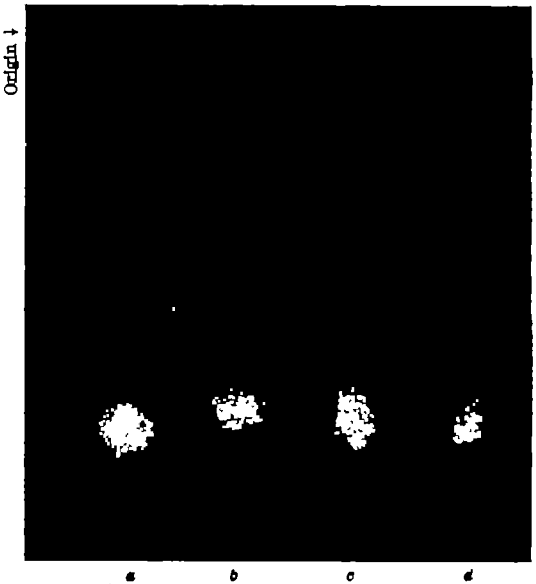

Fig. 3. Solvent: 86 per cent (v/v) aq. *n*-butanol (ref. 4); descending. (*a*) eluate compound (5); (*b*) hydrolysate eluate compound (5); (*c*) hypoxanthine; (*d*) hydrolysate eluate compound (3)

The venom in which inosine and hypoxanthine were identified was a portion of a pooled batch constituting some thousands of venom 'milkings'. While these two substances may have arisen from adenosine by enzymic action during protracted drying of the venom, conclusive proof of this point is beyond the scope of this investigation.

The earlier arguments favouring the existence of the three purine compounds as natural constituents of fresh venom are now substantiated in the identification of adenosine, adenosine 3′-phosphate and guanosine in a perchloric acid extract of freshly ejected venom.

I thank Miss F. Bates for skilled assistance with the chromatography, Mr. J. Thayer for assistance with the ultra-filtration, and Prof. R. K. Morton for his continued interest. I am indebted to the Director of the Healesville Sir Colin Mackenzie Sanctuary, Mr. Gasking, and Mr. Tanner for the supply of fresh venom.

Supposed Asexual Reproduction in Trilobites

The study of the newly discovered recent member of the Cambro-Silurian mollusc group Monoplacophora has caused me to extend investigations also to animals other than molluscs of the early Cambrian fauna. Then, I was struck by the appearance of some Olenellid Trilobites figured by Walcott[1], showing additional segments behind what usually forms the long spine of the last segment (Fig. 1).

These illustrations strongly indicate that asexual budding from the posterior end of the animal was taking place at the time of fossilization, in almost the same manner as is often found in syllid Polychaetes of to-day (Fig. 2—from Malaquin[2]). Although Walcott's figures were published in 1910, explanations of them have been very scarce. Störmer[3] and Snodgrass[4] have redrawn them (Figs. 10 and 1 respectively) without comments, except that Störmer, following usual practice, terms the hindmost segments "segments abortifs".

It would appear more straightforward to suppose these posterior segments to be new ones formed by budding off from the posterior end of the adult *Olenellus*, as explained below.

(1) So far as I have been able to make out, the 'abortive segments' are found exclusively on fully grown specimens. Smaller ones have the same (or in quite juvenile ones fewer) segments as the pre-spinal ones in the adult, but never those extra ones which in later life should become 'abortive'.

(2) In the animal shown in Fig. 1,*A* and *B* the length of each segment is constant from the first one behind the head and including the spine-bearing one, whereas the width of the median part decreases slightly. Behind the spine, all segments are shorter but again uniform in length, whereas the first ones are slightly broader than the last pre-spinal ones (verified on new photographs obtained from the U.S. National Museum by the courtesy of Dr. E. L. Yochelson).

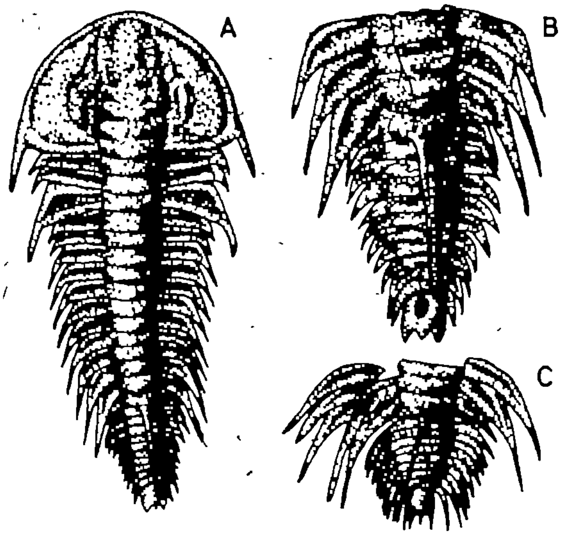

Fig. 1. The trilobite *Olenellus vermontana* (Hall) showing 'abortive segments' behind the normal ones. *B*, an enlarged drawing of the hind part of the specimen shown in *A*; *C* shows another specimen. (From Walcott, redrawn)

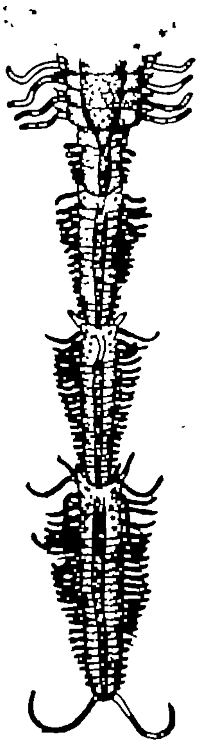

Fig. 2. The Polychaete *Autolytus edwardsi* De St.-J. Posterior part of the body with four rudiments of new animals of different ages budding off. (From Malaquin, redrawn)

(3) The specimen shown in Fig. 1,*C* has the same number of 'abortive' segments as shown in Fig. 1,*A* and *B*, although each one is still shorter. The shortness could be due to one of two causes. Either the segments are in a stage of growth where they have not yet attained full length, as here supposed, or the fossil is from a cast skin where the posterior segments have been so pressed into each other as to appear shortened. As, however, the shortened segments are definitely the post-spinal ones, the anterior ones being unaffected, the latter explanation seems scarcely probable.

(4) The telson forming the posterior end of the 'abortive segments' has a small median spine which could easily grow into a new large spine occupying the usual terminal position in the new animal.

(5) The size of the pleural lobes decreases suddenly at exactly the same place where the segmental length is reduced.

(6) Quite a number of specimens of different species within the family Olenellidae are known to possess 2–6 extra segments behind the spine-bearing one. These cases are supposed here to show the first rudiments of new animals appearing without having reached their final number of segments. Conversely, in the very few cases known where large numbers of 'abortive' segments have been found (up to twenty-nine such ones have been recorded in *Paedeumias robsonensis* Burling[5], here quoted from Raw[6]) these are not all the same size and are partly broken off, indicating that in this case there may have been several more and less-grown rudiments of new animals placed after each other at the posterior end of the animal, in the same way as is often seen in certain recent syllid Annelids (Figs. 2 and 3,*F*). In such cases, it cannot be expected that the number

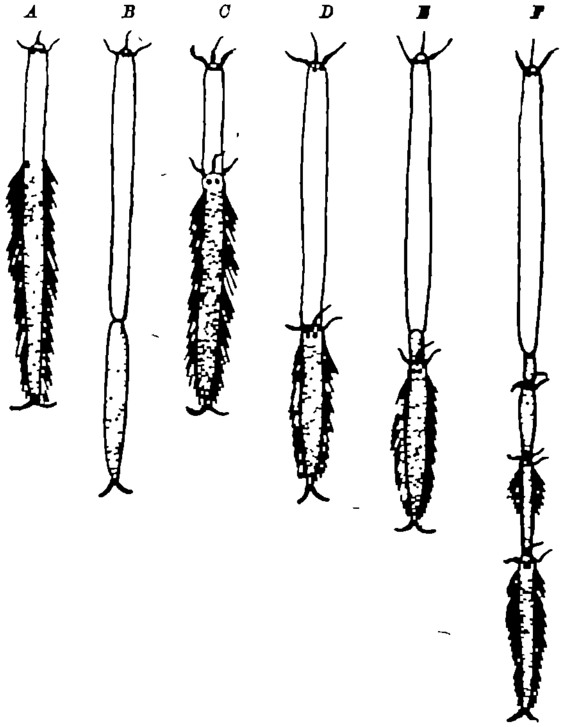

Fig. 3. Diagram of different modes of reproduction in syllid Polychaetes. *B–F*, different types of asexual budding. (From Malaquin, redrawn)

of extra segments falls within that usual to the fossils of the species in question.

(7) Clearly, *Olenellus* is able to develop through larval stages of typical shape, as appears also from Walcott's publication, but I have not seen any record of small specimens of the type on which has been based the generic name *Mesonacis*. As, however, Walcott[1] states that the pre-spinal segments are of *Olenellus* type, but the post-spinal ones of the *Mesonacis* type, and as he makes similar statements concerning the small extra segments in *Paedeumias transitans*, I should be much obliged to palæontologists if they will inform me whether larval or very young specimens of *Mesonacis* type are known. If not, the possibility would exist that *Mesonacis* represents specimens of the sexual, *Olenellus* and *Paedeumias* the asexual generation of different species with metagenesis.

(8) No rudiment of a head has ever been recorded to be intercalated between the spine-bearing segment and the following ones. Thus, as in several recent Polychaetes, the head would seem to have been formed after liberation of the new animal—or at least to have become chitinized after that time. Thus, in fossils, such a head should appear rather suddenly as a broad rudiment which eventually acquired normal shape, whereas specimens developing from larvæ should have narrower heads, shaped much more like those known from, say, *Agnostus*. In the description of *Wanneria walcottanus* (Wanner), Walcott[1] (his Pl. 30, Figs. 3–4) mentions that small and broad cephali exist. These could possibly be taken to have another origin than the narrower ones which certainly arise from growing larvæ.

It may be stressed that the suggestion of asexual propagation in Trilobites cannot hold good except for those forms still missing a true pygidium, that is, it is restricted to the Olenellids. Probably, a well-developed pygidium would constitute an insurmountable difficulty to asexual propagation as here described. The phylogenetical significance of the above suggestions would be in showing that the oldest known family of the Trilobites, the Olenellids, appears to share with primitive Polychaetes a most interesting biological character hitherto unknown in Arthropods.

Rapid Observation of Phase Transformations in Fibrous Proteins using an X-Ray Diffractometer

MANY naturally occurring fibrous materials possess X-ray diffraction patterns with few diffuse and ill-defined spots which defy precise analysis. Nevertheless, phase transitions involving such materials have been extensively studied and a great deal is known about them. Wool keratin, being of great technological importance, has been the subject of many investigations[1]. Of particular interest in the molecular biology of wool keratin are the time-dependent parameters of creep and relaxation and their relation to the stable α and β phases[2]. Little is known of the molecular changes involved during the simple process of stretching a fibre, and the interpretative difficulties are formidable if we must accept the coiled helical system (α) and a simple planar system (β)[3] as the two stable states in the reversible $\alpha \rightleftharpoons \beta$ transformation.

Rapid observation of the X-ray diffraction image during stretching experiments may help to reconcile the difficulties. To this end a number of workers[4] have suggested apparatus whereby diffraction patterns could be quickly observed.

By limiting the data to the equatorial direction, a quick record may be obtained which is sufficiently accurate for many purposes. The method reduces the time required from several minutes (photographically) to a few seconds and when refined will enable a number of interesting time-transient phenomena to be investigated.

The use of a powerful X-ray generator and sensitive quantum detector enabled satisfactory results to be obtained.

A Raymax rotating anode X-ray generator was used, being run at 60 kV. peak and 60 m.amp. for obtaining the patterns of wool keratin, Fig. 1, and somewhat lower for the polythene and cellulose, Fig. 2.

The detector used was a Mullard Geiger–Müller counter, with a quantum efficiency of about 50 per cent, fitted into a modified Hilger diffractometer. Alterations to the diffractometer included reducing the time constant (*RC*) of the integrating circuit to 0·1 sec. and the addition of an auxiliary drive system

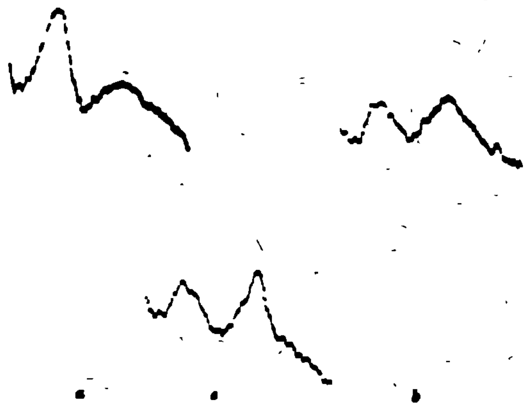

Fig. 1. Equatorial traverse ($5° < 2\theta < 40°$) showing the phase transformation in wool keratin, each diagram being recorded in five seconds. (*a*) Cleaned and Soxhletted α Lincoln wool keratin showing the strong composite reflexion about 9·8 A. and the partly oriented halo; (*b*) Extended 50 per cent in steam, dried and the diffraction pattern obtained within 90 seconds. The group about 9·8 A. is reduced and the characteristic β reflexion about 4·65 A. is quite apparent; (*c*) Further extension to about 75 per cent and the record obtained within four minutes. This is a well-formed β diagram with a strong reflexion about 4·65 A.

to permit scanning at the rate of 2π radians of 2θ per minute.

The outputs from the integrating circuits of both monitor and detector were fed to the amplifier circuits of a Cossor d.c. oscilloscope fitted with a long-persistence cathode-ray tube (Type 89*L*). *x*-Axis shift was obtained from a potentiometer directly coupled to the scanning arm.

Using this device, an image of the pattern was continuously observable on the screen and a fresh pattern, taking five seconds, was presented once every ten seconds. Typical of these records are those shown in Figs. 1 and 2.

An expression for the accuracy of observations with a system like this is given by

$$V\sqrt{NT} = 100$$

where *V* is coefficient of variation, *N* is mean counting-rate, *T* is total time of the scan. *N* is limited by durability and fatigue in the X-ray generator; but the rotating anode tube used enables *N* to be an order of magnitude greater than with a stationary anode type. A further reduction in the time could perhaps be obtained using a pulse technique as in radiographic apparatus.

Equilibrium of the detector response (to within σ) occurs in a time

$$t = \frac{RC}{2} \ln (2NRC)$$

which under the experimental conditions and $N \simeq 1{,}000$ gives $t \simeq 0{\cdot}265$ sec.[5]. This is a little too long to yield an accurate line shape, as is seen by the marked asymmetry in the cellulose profiles; but the time constant could not easily be reduced below 0·1 sec. due to the use of a self-rectifying (50 Herz) tube.

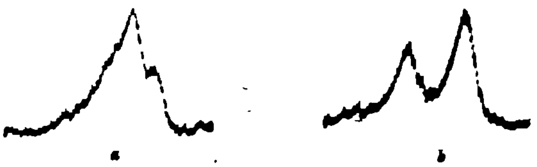

Fig. 2. Equatorial traverse ($5° < 2\theta < 40°$) of (*a*) polythene and (*b*) modified cellulose (Ramie) obtained in five seconds. The cellulose reflexions are those of the 101 and $10\bar{1}$ doublet and the 002. The central beam is on the left-hand side of the diagram.

The true profile $\psi(t)$ may be obtained from the observed profile $\theta(t)$ by using the relationship

$$\psi(t) = \dot{\theta}(t)\, RC + \theta(t)$$

Theoretically, it should be possible to reconstruct a badly distorted curve; but the accuracy of such a procedure may not be high. Difficulties are involved in measuring the gradients and ordinates accurately and the inherent variation in the Poissonian input adds further errors.

Figs. 1 and 2 show in general the scope of the technique and its use for rapid diagnosis.

Fig. 1 is a simple stretching experiment carried out on a bundle of Lincoln wool keratin. The aim was to achieve a rapid phase transition; but practical manipulative difficulties introduced time limitations.

By comparing these patterns with those obtained in a more prolonged diffractometric investigation it appears probable that the transients involved in the α–β transformation in steam must occur in times less than those between the end-points of this experiment.

A process of ballistic extension (without rupture) might enable more rapid extensions to be achieved as the time taken to secure the diffraction data is not now the limiting factor in this type of experiment.

A Unified Theory of the Mechanism of Inhibition of Corrosion of Iron in Acid and Neutral Media based on the Electrocapillary Behaviour of Ions

AN attempt has been made to develop a single theory to explain the inhibition of corrosion of iron in both neutral and acid media on the basis of the electrical affinity of the metal/solution interface towards ions or neutral molecules present in the solution.

At a metal/solution interface there exists an electrical double layer the nature and composition of which depend upon the nature of the metal, the ions present in the solution and the potential difference existing between the metal and the solution. Let us examine the behaviour of this double layer on the basis of the electrocapillary phenomenon. *ACB* (Fig. 1) represents an electrocapillary curve of mercury for cations and anions such as Na^+, K^+ and Cl', SO_4'', NO_3' respectively. *C* represents the electrocapillary maximum. In the presence of cations or anions which are preferentially adsorbed, that is, capillary active, the e.c.m. is depressed and also shifted. A capillary active anion displaces the ascending portion (positive limb) and the maximum of the curve towards the right (*DC′B*), showing that at potentials positive to the e.c.m., this type of ion has a greater affinity for the metal surface than

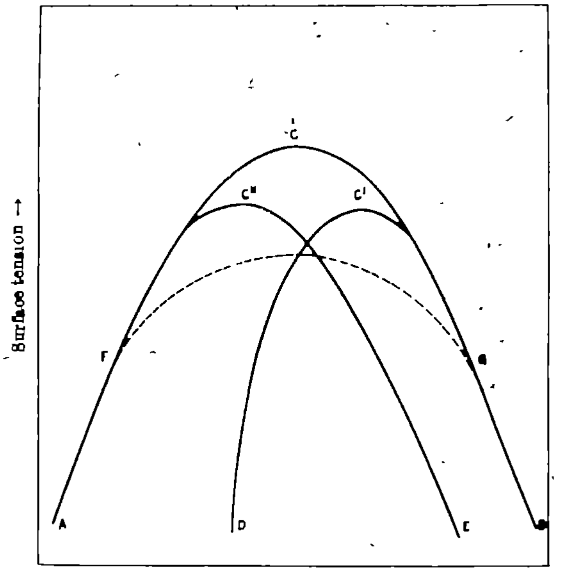

Fig. 1. Electrocapillarity curves for mercury in various solutions (schematic)

normal anions. Capillary active cations displace the descending limb towards the left ($AC''E$). Neutral molecules depress the upper portion of the curve (Fig. 1, FG).

Most of the experimental data on the electrocapillary effect refer to mercury the e.c.m. of which in the presence of inactive ions is about $-0{\cdot}2$ V. (H scale). Electrocapillary curves for liquid metals such as gallium and mercury amalgams and solid metals such as platinum and zinc have been reported to be similar in nature to those of mercury but with different values of the e.c.m. Ayazyan has recently reported a value of about $-0{\cdot}37$ V. for iron in sulphuric acid ($0{\cdot}001$ N) from the study of double-layer capacity at different electrode potentials[1].

When a specimen of mild steel bearing its air-formed oxide film is immersed in aqueous solution, the potential at the metal/solution interface is not uniform, the surface being divided into local cathodic and anodic areas. The oxide-covered portions of the surface are in the main cathodic, strained and defective areas in this oxide film forming anodic areas. The cathodic reaction is, in general, either the conversion of oxygen into hydroxyl ion or liberation of hydrogen, depending upon the pH and dissolved oxygen content of the solution. Evans and Hoar[2] have distinguished these zones in a corroding specimen and have measured their potentials in different electrolytes. The cathodic areas are always at a more positive potential than the anodic areas (see schematic cathodic and anodic polarization curves, Fig. 2). Approximate potentials existing at anodic and cathodic areas are indicated by the potentials given respectively by freely rusting iron ($-0{\cdot}5$ V.) and inhibited or passivated iron ($0{\cdot}0$ V.).

Let us now consider the behaviour of the metal/solution interface when the mild steel is immersed in a neutral medium containing electrolytes. If the value of e.c.m. of iron be assumed to be in the neighbourhood of $-0{\cdot}37$ V., then since the potential of the anodic areas is in the region of $-0{\cdot}4$ to $-0{\cdot}5$ V. and that of the cathodes is relatively more positive, it may be presumed, from an analogy with the electrocapillary curves of mercury, that anions present in the solution will be preferentially adsorbed in the cathodic areas rather than on the anodic areas. The degree of adsorption of the anion will, however, depend upon its nature—chloride, sulphate and nitrate being weakly adsorbed while capillary active anions (benzoate, salicylate, cinnamate) are more strongly adsorbed. The present theory requires that inhibitive anions such as benzoate, phosphate and chromate are capillary active and are adsorbed on the cathodic areas more strongly than are normal anions such as chloride, sulphate and nitrate, which are neither capillary active nor inhibitive. The value of the cathodic potential relative to that of the positive limb of the electrocapillary curve should determine the efficiency of adsorption. It may be noted that the greater adsorption of chromate, phosphate and benzoate ions relative to that of chloride on the surface of magnetite suspensions has been reported by Anderson[3] from electrophoretic zeta-potential measurements.

The theory further requires that the adsorption of the capillary active ions at the cathode should interfere with the cathodic depolarization by oxygen, this in turn diminishing the rate of dissolution of iron at the anode. The limited concentration of dissolved oxygen present in the solution can therefore oxidize the iron before it can enter solution from the anodic areas, thus completing the passivation. Rozenfeld and Akimov[4] have shown that chromate can cause cathodic polarization.

In neutral solution, therefore, if the postulated mechanism is correct, anions such as phosphate, benzoate, chromate, are primarily cathodic inhibitors, though the oxidizing anions chromate and nitrite can additionally produce anodic polarization. In con-

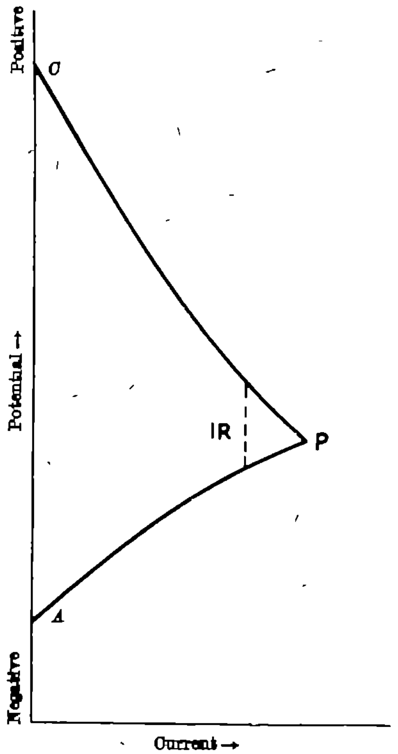

Fig. 2. Cathodic and anodic polarization curves (schematic)

firmation of this, the non-oxidizing inhibitors have been found to give 'corroding' potentials in the absence of oxygen[4].

In the case of iron in contact with acid, the air-formed oxide film is absent, and the potential of the cathodic areas approaches that of the anodic areas. The potential of the major portion of the surface (anodic) will remain at values more negative than the e.c.m. Capillary active cations such as alkyl ammonium ions and other basic nitrogen-containing cations will be preferentially adsorbed on the anodic areas reducing anodic dissolution. Non-ionic capillary active compounds such as thiourea depress the electrocapillary curve, flattening it near the e.c.m.[6], indicating that this type of inhibitor could be absorbed both on the anodic and cathodic areas. Hoar and Holliday[7] and Ride[8] have reported from their polarization studies of acid inhibitors that quinolines and aliphatic amines behave mainly as anodic inhibitors while thioureas polarize both the anodes and cathodes.

The above tentative mechanism can explain some of the facts known about inhibition. Experimental investigations will be undertaken to test this hypothesis. It will also be interesting to correlate the capillary active and inhibitive properties of the ion with their internal structure.

Many investigators have discussed the function of adsorption to explain corrosion inhibition, but I am not aware of any previous treatment of corrosion inhibition in terms of electrocapillary action.

I am indebted to Miss D. M. Brasher for stimulating discussions and helpful suggestions made while this communication was being written. I am also grateful to Dr. F. Wormwell for his encouragement and advice. This is published by permission of the Director of the Chemical Research Laboratory.

Titration of Mixtures of Acids

The determination of the degree of polymerization of polyamides or polypeptides by end-group titration is, in effect, a determination of the amount of the weakly acidic carboxyl group (dissociation constant K_2) in presence of a large excess of the base of a stronger acid, the amide or peptide group (dissociation constant K_1).

A similar, but simpler, problem arises in the titration of weak dibasic acids when it is usually assumed[1] that if K_1/K_2 is greater than 4 the titration curve can be distinguished from that of a monobasic acid. Calculated titration curves for dibasic acids having different values of K_1/K_2 ranging from 4 to 100 show that it must be far larger than 4 before the end-point of the weaker acid can be visually detected.

The following argument leads to a more general relationship which can be applied to all mixtures of two acids, and which agrees with the conclusion drawn from the calculated curves.

If a_1 is the concentration of the stronger acid, and a_2 that of the weaker acid, then if the total concentration of acid in the undissociated form is A (when the hydrogen ion activity is H), the slope of the titration curve is given by:

$$\frac{\mathrm{d}A}{\mathrm{d}(pH)} = -2\cdot303\left[\frac{K_1a_1H}{(K_1+H)^2}+\frac{K_2a_2H}{(K_2+H)^2}\right] \quad (1)$$

Consider the central point of inflexion of this curve. There, $K_1 > H > K_2$, and at this point, to a sufficiently close approximation,

$$\frac{\mathrm{d}A}{\mathrm{d}(p\mathrm{H})} = -2\cdot303\left(\frac{Ha_1}{K_1}+\frac{K_2a_2}{H}\right) \quad (2)$$

Differentiating (2) and equating to zero (for a point of inflexion) gives:

$$\frac{\mathrm{d}^2A}{\mathrm{d}(p\mathrm{H})^2} = (2\cdot303)^2\left(\frac{a_1}{K_1}-\frac{K_2a_2}{H^2}\right) = 0 \quad (3)$$

Hence, here

$$H^2 = K_1K_2\left(\frac{a_2}{a_1}\right) \quad (4)$$

and

$$\frac{\mathrm{d}A}{\mathrm{d}(p\mathrm{H})} = -4\cdot606\sqrt{\frac{K_1a_1a_2}{K_2}} \quad (5)$$

Unless the slope of the curve at this point differs from that at the mid-point of the weaker acid, there will be no perceptible point of inflexion. At this mid-point, $H = K_2$ and (1) assumes the form:

$$\frac{\mathrm{d}A}{\mathrm{d}(p\mathrm{H})} = -2\cdot303\left(\frac{K_2a_1}{K_1}+\frac{a_2}{4}\right) \quad (6)$$

Equations (5) and (6) thus give the condition for the detection of the end-point of complete titration of the weaker acid, namely:

$$\sqrt{\frac{K_1a_1a_2}{K_2}} > \frac{K_2a_1}{K_1}+\frac{a_2}{4} \quad (7)$$

or

$$K_1/K_2 > 59\cdot7\ (a_1/a_2) \quad (7a)$$

For a dibasic acid, $a_1 = a_2$; thus the ratio of the dissociation constants must be larger than 59·7, not 4, before each group can be distinguished in the titration curve. This is in close agreement with the empirical conclusion reached by studying the theoretical curves.

It also follows that for a polymer containing a_1 amide groups and a_2 carboxyl end-groups, the degree of polymerization (a_1/a_2) must not be too large or, for a given ratio of dissociation constants, the end-point corresponding to complete titration of the carboxyl groups will be undetectable. In polyglycine, for example, pK_2 appears to be about 3·0 (according to data for its titration with hydrochloric acid), whereas pK_1 seems to be about zero[2]. With this polymer, therefore, the highest degree of polymerization which can be determined by hydrochloric acid titration is 1,000/59·7 = 16. Meggy and Sims[3] were able to overcome this limitation by using colour acids which, in effect, increase the affinity of the groups responsible for colour take-up and thereby effectively vary the *pK* of these groups. Similar conclusions can be drawn from published data for nylon[3], and it is obvious that the above result has wide applicability.

Recrystallization and the Ductility of Chromium

UNUSUAL features observed during work on the ductility of chromium were the difficulty of detecting the completion of recrystallization of cold-worked material and the sensitivity of the ductile/brittle transition temperature of recrystallized material to small amounts of deformation, either residual or imposed.

The transition temperature of cold-rolled chromium (0·002 wt.-per cent nitrogen, 0·01 wt.-per cent oxygen) increased from − 60° C. to 130° C. or 380° C. on annealing at 1,050° C. or 1,100° C. respectively. Both treatments appeared to give completely recrystallized material of similar grain-size as judged by microscopic and normal X-ray back-reflexion examination. A distinction between the two materials could, however, be made using the more sensitive micro-focus X-ray technique, which revealed that the specimens annealed at 1,050° C. were not free from strain while those annealed at 1,100° C. were. This apparent marked dependence of transition temperature on residual cold work could explain the comparatively low and variable increases in transition temperature (70–200° C.) recorded by other workers on recrystallizing cold-worked chromium[1,2], although nitrogen content might also be important in this regard.

The following experiments indicate the sensitivity of the ductile/brittle transition temperature of recrystallized chromium to small amounts of deformation and emphasize the value of the micro-focus technique. As noted previously, wrought chromium strip recrystallized by annealing at 1,100° C. for two hours had a transition temperature of 380° C. However, similar strip sheath-rolled in mild steel and given an identical thermal treatment in the sheath had a consistently low transition temperature around − 55° C. Three possible explanations of this effect were suggested: (1) brittleness of the vacuum-treated specimens was due to impurity pick-up which did not occur in sheathed specimens; (2) heating-rate as well as cooling-rate could have been a factor as has been found with molybdenum[2]; (3) the low transition temperature of sheathed specimens was a result of deformation of the specimen by the sheath during cooling due to differential thermal contraction.

Neither of the first two possibilities was particularly attractive, and each was readily disproved by experiment. To test the third possibility, a type of 'sandwich' specimen was used comprising a strip of chromium between two much thicker strips of mild steel, the whole assembly being sealed under argon in a close-fitting mild-steel capsule. In one set of specimens the chromium and mild-steel 'sandwich' components were welded together at their ends before being sealed into the capsule, while in the other set the ends were left free. After heating the capsules at 1,100° C. in air for 2 hr. and slow cooling, it was found that the chromium strips which had been forced to expand and contract with the mild steel during heating and cooling were ductile at 0° C. whereas the remainder were brittle. No deformation could be detected in any of these specimens by the normal X-ray back-reflexion method. However, the micro-focus technique showed evidence of plastic deformation (~ 0·1 per cent strain) in strips which had been welded to their mild-steel supports while none could be detected in unwelded specimens.

Brandes and co-workers[4] have reported that compacted flake chromium, extruded at 1,200° C. in a sheath, can show ductility in bending at − 30° C. even though the nitrogen content was as high as 0·091 wt.-per cent. X-ray diffraction photographs of the material showed full recrystallization. The above work would indicate that Brandes's result possibly arose because (*a*) the material was not in fact fully recrystallized or (*b*) deformation occurred during cooling after extrusion due to a sheath effect and that the X-ray technique used was not sufficiently sensitive to detect residual cold work arising from either of these possibilities. Another possible explanation is that it is understood that the practice in Brandes's work was to determine the lowest temperature at which deformation occurred by bending a single specimen at an elevated temperature initially and then at successively lower temperatures until finally it broke in a brittle manner. Other work[3,5] indicates that this is not a valid procedure if an accurate measure of transition temperature is required.

Strain-Age Hardening and Brittleness in Chromium

CURRENT theories of the cause of brittleness in 'pure' chromium ascribe the phenomenon to Cottrell locking[1], invoking the Mott–Stroh[2,3] theory of crack formation as the operative mechanism of brittle fracture, and nitrogen as the associated interstitial solute atom. There are several features of the tensile behaviour of annealed chromium (containing approximately 0·002 per cent nitrogen and 0·015 per cent oxygen), however, which this picture does not wholly explain, namely: (1) the very high temperature up to which embrittlement extends (about 350° C.)

compared with other body-centred cubic metals of similar structure such as α-iron, molybdenum and tungsten; (2) the abrupt nature of the transition from a highly ductile condition to a completely brittle one, behaviour which again differs markedly from other body-centred cubic metals; (3) the fact that embrittlement occurs (at this nitrogen level) at the bottom of a trough in the maximum stress/temperature and yield stress/temperature curves just below 350° C.[4], and not on the steeply rising part of the yield stress/temperature curve, which occurs only below 200° C., and which has been ascribed directly to Cottrell locking.

Evidence is accumulating at these Laboratories which suggests that embrittlement of chromium may be caused primarily by the strain-induced precipitation, from highly super-saturated solid solution, of a chromium nitride and possibly also of a chromium oxide. The process appears to be highly sensitive to applied plastic strains, and to some extent resembles the strain–age hardening process which occurs in α-iron containing nitrogen[5].

Extrapolation of current data[6] suggests a solid solubility of about 10^{-3} per cent nitrogen in chromium at 400° C., falling to 10^{-13} per cent at 200° C.; it is to be expected, therefore, that almost the whole of the nitrogen ($1 \cdot 5 \times 10^{-3}$ wt. per cent) in chromium of the present purity would be available for precipitation between 400° C. and 200° C., a range of temperature which coincides with the ductile-brittle transition in this material in the annealed condition.

Evidence for the strain–age hardening process in pure chromium may be summarized as follows: (1) Repeated straining in tension to just beyond the yield point at 400° C. results in a distinctly stepped curve typical of an age-hardening alloy[7] as shown in Fig. 1, where the flow stresses of successive loadings rise appreciably above the preceding maximum applied stress. This effect occurs in varying degrees between 200° C. and 500° C., as shown in Fig. 2. The increment in flow stress was in general more sensitive to temperature and strain than to time of ageing between successive strains, that is, precipitation occurred mainly during or immediately after straining. Accordingly, the results in Fig. 2 are plotted as increment in flow stress against number of strainings.

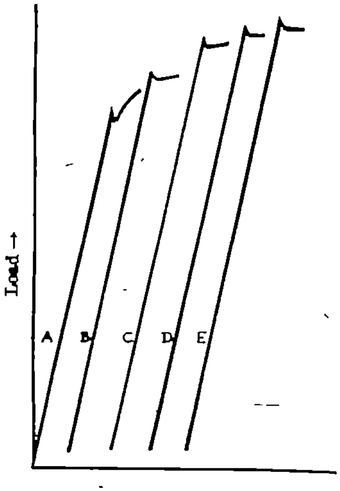

Fig. 1. Interrupted-loading tensile curves on high purity chromium at 400° C. (*A*) Strain, 1·1 per cent, 400° C.; (*B*) age, 1 min.; (*C*) age, 1,000 min.; (*D*) age, 1 min.; (*E*) age, 2 min

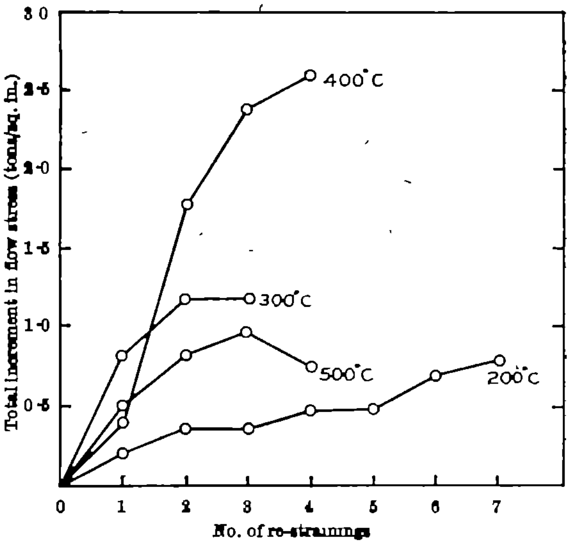

Fig. 2. Effect of temperature on the strain-age hardening of high purity chromium (0·0015 per cent nitrogen, 0·02 per cent oxygen).

(2) Pronounced age-hardening has been observed between 200° C. and 400° C. on chromium samples quenched from 1,250° C. Samples containing from 0·1 per cent down to 0·005 per cent nitrogen contained traces of precipitated particles in the microstructure which were revealed under phase contrast. Age-hardening also occurred at a level of 0·0015 per cent nitrogen, but no precipitated particles were visible.

(3) The ductile-brittle transition in tension of annealed chromium was lowered from 350° C. to 150° C. by lowering the nitrogen content from 0·0015 per cent to 0·0005 per cent. In this latter case brittle fracture occurred on the rising part of the yield stress/temperature curve in a manner similar to other body-centred cubic metals, but the brittle fracture stress was still comparatively low. This lowering of the transition temperature may be ascribed to the reduction of the mass-embrittling effects of precipitation consequent on a lower order of solute content; the abrupt incidence of completely brittle fracture below 150° C. indicates, however, that the precipitation mechanism continues to operate even at this low level of nitrogen.

(4) Deformation in the ductile range (that is, at 350° C. or above) results in a substantial lowering of the ductile-brittle transition, for example, a prestrain as small as 3 per cent at 400° C. resulted in high ductility at room temperature, with an elongation of 63 per cent and a reduction of area of 76 per cent. A notable feature of these tests was the lowering of the yield stress from 20–25 tons per square inch in the unstrained (brittle) condition to 15 tons per square inch in the prestrained (ductile) condition. The explanation now offered for this behaviour is that prestraining accelerates precipitation of nitride and that under appropriate conditions (for example, about 3 per cent strain at 400° C.) over-ageing advances far enough to depress the ductile-brittle transition to below room temperature. Further evidence for this view will be advanced in a paper shortly to be published.

In view of the strong affinity of chromium for nitrogen (binding energy at 20° C. approximately 1 eV.)[8], the precipitated chromium nitrides would be expected to be stable, and would be unaffected by the 'dissolving' effect of adjacent unsaturated dislocations (the binding energy of which for nitrogen would be expected to be similar to that in iron, about 0·45 eV.)[9]. Precipitation at an intermediate temperature (such as 400° C.) would therefore be expected permanently to remove nitrogen from solution and reduce the amount remaining to cause brittleness at lower temperatures.

I am indebted to Mr. J. I. Nish for many useful discussions on this subject. Acknowledgment is also made to the Chief Scientist, Department of Supply, for permission to publish this communication.

Effect of Stress on Hole Formation during the Diffusion of Zinc from Brass *in vacuo*

IT has been suggested by Greenwood[1] that intergranular fracture during deformation at elevated temperatures, which occurs by the linking together of isolated holes at grain boundaries, is the result of precipitation of excess vacancies produced by the deformation. Some doubts have been cast on this view. For example, in diffusion couples, holes may be formed by the precipitation of excess vacancies produced by the unequal rates of diffusion of the components, but these holes have little preference for grain boundaries. An exception to this can occur, however, during the diffusion of zinc from brass *in vacuo*, and Balluffi and Seigle[2] have suggested, without proof, that in this case the preferential formation of holes at grain boundaries is associated with the presence of stress.

In the course of an investigation of the effect of applied stresses on brass foils, 0·001 in. thick, during the removal of zinc by diffusion *in vacuo* it has been found that the presence of stress markedly affects the distribution of holes. Fig. 1,*a* shows randomly distributed holes in a brass foil containing 0·2 per cent antimony which was tested free of stress *in vacuo* for 1 hr. at 800° C. to remove nearly all the zinc. I have shown previously[3] that the presence of 0·2 per cent antimony enhances the formation of holes during the removal of zinc. The same material fractured after 5 min. under a nominal stress of 170 gm./mm.[2], and Fig. 1,*b* shows that at this time the holes had formed preferentially at grain boundaries. To show that these cracks at grain boundaries were not due to the applied stress in the absence of an excess of vacancies produced by diffusion, a specimen was tested under the same conditions except that, to prevent removal of the zinc, the specimen was surrounded by an atmosphere of oxygen-free nitrogen and by a tube of the same composition as the specimen open only at the end through which the load was applied by a fine wire. There was no change of length of this specimen, and a micro-section showed no holes either at grain boundaries or within the grains. A test on a copper–0·2 per cent antimony alloy containing no zinc similarly produced no holes, although there was a slight extension of 1·3 per cent. Thus the presence of stress alone before or after the removal of zinc did not produce intergranular cracks. It can therefore be concluded that under these conditions of test the simultaneous action of stress and of excess of vacancies is necessary to produce holes and cracks forming preferentially at grain boundaries.

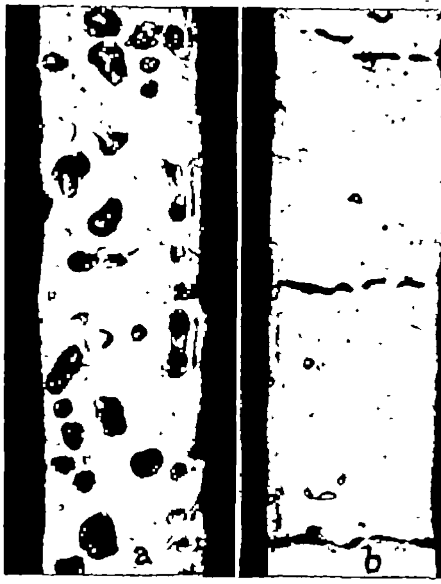

Fig. 1. Brass containing 0·2 per cent antimony. (*a*) Tested free of stress. Random distribution of holes. (*b*) Broke after 5 min. under stress. Preferential formation of holes at grain boundaries × 750

Duration of Transients in Solar Radio Noise

SINCE February this year, high-speed records have been obtained at a frequency of 200 Mc./sec. during solar radio noise storms. The equipment used for the registrations consists of a receiver with bandwidth of 0·3 Mc./sec. and time constant 0·01 sec. and a Brush recorder. Records were secured at

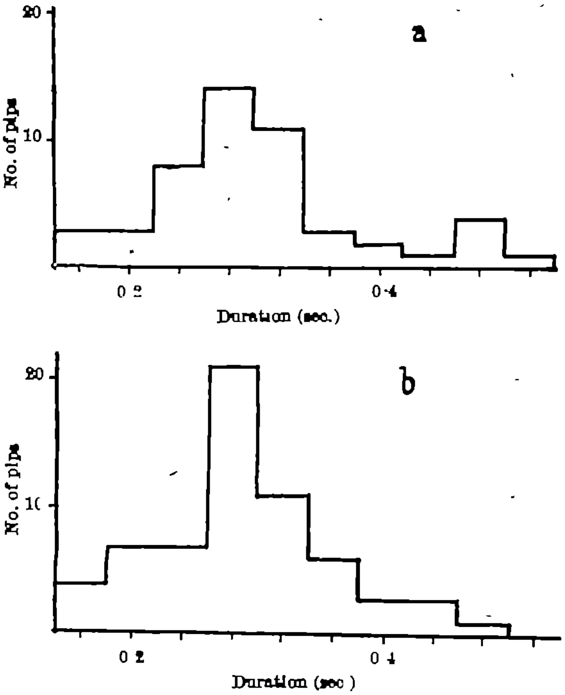

Fig. 1. Distribution of pips of different duration (a) May 9 and (b) August 28, 1957

various paper speeds, with a speed of 25 mm./sec. as that mostly used, since this speed seems to give the best compromise between the competing factors resolving power, amount of information and paper consumption.

Records show that bursts, as recorded on a usual low-speed recorder, can be resolved into several pips. Measurements of the duration of these pips, taken between half-power points, have been carried out on records from May 9 and August 28 this year. The histograms of Fig. 1 show the distribution of pips of different duration. In the first case, 50 pips were analysed, in the second 64 pips. Both histograms reveal a rather sharp peak at 0·28 sec. The mean duration of pips on the two days was found to be: May 9, 0·30 ± 0·02 sec.; and August 28, 0·28 ± 0·01 sec.

A remarkable feature of the records taken is that pips have a strong tendency to occur in groups. The interval between successive pips was measured for several groups, and the following mean values were obtained: May 9, 0·51 ± 0·02 sec.; and August 28, 0·54 ± 0·03 sec.

At a frequency of 400 Mc./sec., de Groot[1] reports a sharp maximum for a duration of 0·18 ± 0·03 sec. in his material of 500 bursts covering several noise storm periods. On the particular date August 29, 1956, the mean duration of pips was 0·13 ± 0·03 sec., and the mean interval between successive pips was 0·25 ± 0·03 sec.

Comparing these results with my observations, it is seen that the mean duration of pips is halved when the wave-length is doubled. This supports the results reported by Reber[2] that there is a linear relationship between wave-length in metres and duration of pips in seconds. The constant of proportionality is close to 0·2 and not unity as mentioned by Reber.

The fact that the frequency of occurrence of pips is halved when the wave-length is doubled is interesting, and supports the suggestion by de Groot that this may be an important quantity for the theoretical interpretation.

Use of the Term 'Young's Equation' for Contact Angles

RECENTLY, many writers have called the equation:

$$\gamma_S = \gamma_{SL} + \gamma_L \cos\theta \qquad (1)$$

in which θ is the contact angle measured in the liquid, γ_L, γ_S and γ_{SL} the surface tensions of liquid, solid and solid–liquid surfaces, 'Young's equation'. I suggest that the relation between work of adhesion W_{SL}, contact angle, and surface tension of the liquid:

$$W_{SL} = \gamma_L(1 + \cos\theta) \qquad (2)$$

would more appropriately be called 'Young's equation'. In his "Essay on the Cohesion of Fluids", Thomas Young[1] began his section VII, on "Cohesive Attraction of Solids and Fluids", thus:

"When the attraction of the particles of a fluid for a solid is less than their attraction for each other [that is, when $W_{SL} < 2\gamma_L$] there will be an equilibrium of the surface forces, if the surface of the fluid make with that of the solid a certain angle, the versed sine of which is to the diameter, as the mutual attraction of the fluid and solid particles [W_{SL}] is to the attraction of the particles of the fluid among each other [$2\gamma_L$]." It becomes clear later, when Young discusses the forces parallel to the surface, that his angle (φ) is the supplement of the usual contact angle θ in the liquid. The ratio of versed sine to diameter is $(1 - \cos\varphi)/2$ or $(1 + \cos\theta)/2$. Young's extraordinary insight in seeing, apparently without formal derivation, that this ratio equals $W_{SL}/2\gamma_L$, thus stating equation 2 in archaic but quite definite trigonometrical terms, could properly be commemorated by giving his name to this equation. Equation 1, obtained by merely resolving the forces parallel to the solid surface, is not only almost self-evident but also is far less useful than (2), since the two solid surface tensions γ_S and γ_{SL} cannot be measured with any accuracy. Young not only stated equation 2 but he also indicated its limitation, for it becomes meaningless when W_{SL} is greater than $2\gamma_L$.

Perhaps the reason why recent writers have not called equation 2 by Young's name is that Harkins and Livingston[2], for no very obvious reason, said that "it is extremely unfortunate that this equation came into notice at all", and deprecated its attribution to Young because he stated it in words, the significance of which they found "not clear". I hope the above quotation and comments now show that the relation (2) was clearly understood and stated by Young. The only "unfortunate" incident may be that Young's name has recently been attached to the less important and more obvious relation (1), instead of to the very illuminating (2), which is much the more important discovery, because it relates the contact angle to the relative adhesion of liquid to solid and of liquid to liquid.

Relation of Size of Electroretinogram to Rhodopsin Concentration in Normal Human Beings and one Totally Colour Blind

The surprising fact that during regeneration of rhodopsin in the dark after sufficient light adaptation the electroretinogram does not begin to increase in size until some 50 per cent rhodopsin has been regenerated was originally demonstrated in cats and frogs[1]. Fig. 1 (open circles) shows that also in light-adapted man (three cases) there is an initial phase of very slow recovery of the *b*-wave of the electroretinogram in the dark, followed by a faster rise. On the suspicion that the initial delayed recovery might be due to a general suppression of rod-action on the part of the cones the experiment was repeated with a cone-blind woman. Her electroretinogram (Fig. 1, filled circles), indeed, showed no initial period of delay but began to rise immediately, as does regeneration of rhodopsin. It was 3 min. before the controls showed any response at all.

Fig. 2 is a comparison of the electroretinographic data with rhodopsin densities during regeneration in the dark, as directly determined[2] by Rushton's ophthalmoscopic method. The rhodopsin densities (crosses) are in good agreement with the electroretinographic values of the totally cone-blind, replotted in the figure on a percentage basis (filled circles), while the normal eyes (open circles, also replotted from Fig. 1) show the delay. At this stage no stress is laid on the precise agreement between the two sets of data, only on the absence of delay in the electroretinogram of the totally colour blind. The results, therefore, bear out the hypothesis that the delayed recovery of the electroretinogram in the dark is caused by a state of suppression exerted by active cones on rods. The delayed rise has parallels in perception.

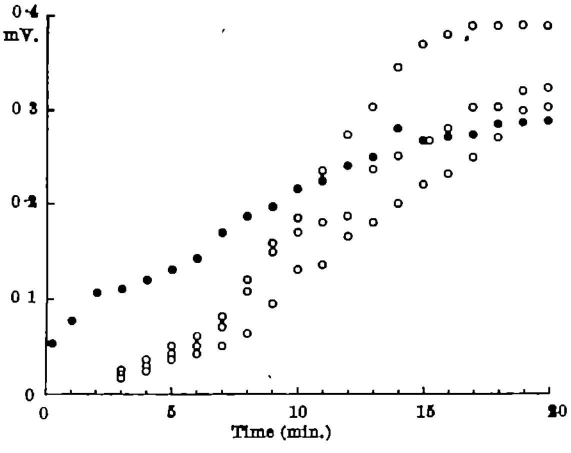

Fig. 1. Increase in mV. in the dark of the *b*-wave of the electroretinogram of one totally colour blind (filled circles) and three controls (open circles), one of which has a particularly large *b*-wave in the dark though none immediately after light adaptation. Light adaptation for 10 min. to 1,000 Lux white light. For the first 3 min. the controls did not have any measurable electroretinogram whereas the totally colour blind immediately responded with a small *b*-wave

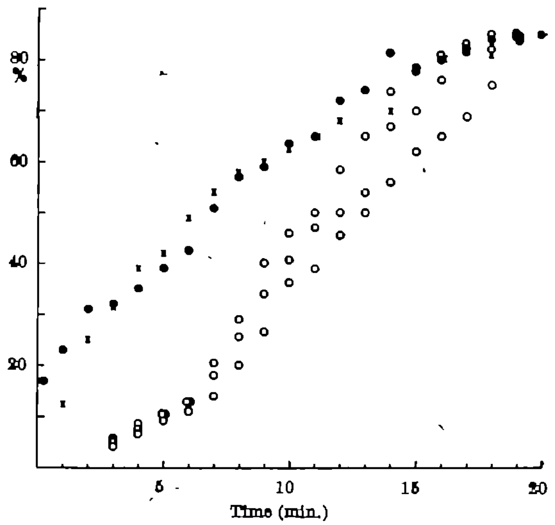

Fig. 2. Plot of percentage regeneration in man (crosses) of rhodopsin (ref. 2) and of size of *b*-waves as in Fig. 1 with the 20-min. value at 85 per cent. Totally colour blind (filled circles) and controls (open circles)

The Hyaluronidase of the Leech: an Endoglucuronidase

Two types of hyaluronidases have been described: one, found in testicular extracts and in snake venom, randomly cleaves the hexosaminidic bonds and yields a consecutive series from disaccharide through higher homologues of disaccharide units[1]; the other, found in micro-organisms, yields a Δ4–5 (glucuronido) unsaturated disaccharide[2]. In this communication, a third type of hyaluronidase is described, found thus far only in extracts of the leech (*Hirudo medicinalis*), which hydrolyses the endoglucuronidic linkages of hyaluronic acid.

The presence in the leech of a potent hyaluronidase had been noted previously, including its effect on the physical properties of hyaluronic acid, the production of reducing sugars and its action as a spreading factor[3]. Paper chromatograms of the products of the 24-hr. digestion of sodium hyaluronate by the leech enzyme and by testicular hyaluronidase[1] showed a similar distribution of oligosaccharides. The leech digest products had, however, slower mobilities and also differed markedly from those obtained by microbial hyaluronidase. The major fraction of 'leech' oligosaccharides (on exhaustive digestion) was isolated by ion exchange chromatography. On paper, it produced a single spot with a

Table 1

Tetrasaccharides	Hexosamine (per cent)	Uronic acid (per cent)	Acetylglucosamine colour (per cent)	Reducing sugar (per cent)
Testis enzyme ($U-A-U-A\cdot$)	43	40	68	53
Leech enzyme ($A-U-A-U\cdot$)	38	45	18*	37
Reduced leech tetrasaccharide	38	20		1

U = uronic acid; A = acetylhexosamine. $A\cdot$ and $U\cdot$ denote the reducing end.

* Theoretically, this compound should give no acetylglucosamine colour. However, under the conditions of the reaction (0·5 N sodium carbonate at 100°) some end-group degradation occurs. Similar AGA values were obtained with $U-A-U\cdot$ and $A-U\cdot$ as described.

slightly slower mobility than 'testicular' tetrasaccharide[1]. The analyses of the two oligosaccharides are compared in Table 1.

The two oligosaccharides have similar compositions, but differ markedly in the acetylglucosamine end-group colour value[1] and in reducing value. On reduction with borohydride, the uronic acid content of the leech oligosaccharide drops to approximately one-half, while the hexosamine remains unchanged. We conclude from the analysis and general properties that the 'leech' oligosaccharide, in contrast to the 'testicular' tetrasaccharide, is a tetrasaccharide having a uronic acid at the reducing end-group. This finding indicates that the leech enzyme hydrolyses endo-glucuronidic bonds, while testicular and microbial hyaluronidases split endohexosaminidic bonds. In accordance with this hypothesis, hexasaccharide (from testicular digests[1] ($U-A-U-A-U-A\cdot$) was hydrolysed by the leech enzyme to two trisaccharides of the composition $U-A-U\cdot$ and $A-U-A\cdot$. No reducing hexosamine end-group was ever found in 'leech' digests of hyaluronic acid. No transglycosylative action[4], in contrast to that of testicular and snake venom hyaluronidase, was observed on 'leech' oligosaccharides or on 'testicular' oligosaccharides with leech enzyme. Furthermore, leech extracts do not contain an exoglucuronidase[5].

Confirmation of the structure of the leech oligosaccharides has been obtained by the action of weak alkali on various oligosaccharide fractions. On treatment of N-acetylhyalobiuronic acid[1] with saturated lime water at room temperature for 4 hr., glucuronic acid and anhydroacetylglucosamine are obtained. This reaction is analogous to the action of alkali on various disaccharides, including galactosido-N-acetylglucosamine[6]. D-Glucuronic acid was stable under our conditions. When 'testicular' hyaluronate tetrasaccharide ($U-A-U-A\cdot$) was treated with lime water, anhydro-N-acetylglucosamine and the alkali-stable trisaccharide $U-A-U\cdot$ were obtained. The composition of the trisaccharide was confirmed by analysis and its properties. From this trisaccharide, the disaccharide $A-U\cdot$ (an isomer of N-acetylhyalobiuronic acid) was prepared by hydrolysis of the non-reducing uronic acid with β-glucuronidase[5]. From leech tetrasaccharide ($A-U-A-U\cdot$), a trisaccharide ($U-A-U\cdot$) and free N-acetylglucosamine were obtained after hydrolysis of the non-reducing glucosamine end-group with liver β-glucosaminidase, which had been shown previously to split N-acetylglucosamine only from the non-reducing end of odd-numbered oligosaccharides[5]. The trisaccharide $U-A-U\cdot$ was identical in R_F value, in composition, reducing and acetylglucosamine end-group value (see footnote of Table 1) with that obtained by treatment with lime water of $U-A-U-A\cdot$ (the 'normal' tetrasaccharide of hyaluronic acid). These results confirm the structure of the leech tetrasaccharide as $A-U-A-U\cdot$.

The compounds obtained by leech hyaluronidase and by the combination of alkaline and enzymatic degradation represent a new series of oligosaccharides derived from hyaluronic acid. Therefore, it is now possible to prepare oligosaccharides with any combination of reducing and non-reducing end-groups. These may be useful in biosynthetic studies.

A Highly Specific Growth-inhibitory Factor produced by Certain *Acetobacter* Species

RECENT studies[1] with a cellulose-producing culture of *Acetobacter acetigenum* NCIB 8132 revealed that this culture contained mutant organisms which were unable to produce extracellular cellulose (celluloseless mutants). Their presence in the wild-type culture was indicated by a mass-plating technique in which a large inoculum from a cellulose-producing culture was spread on the surface of glucose (3 per cent, w./v.), 'Difco' yeast-extract (0·5 per cent, w./v.) (*GYE*) medium (pH 7·0) containing agar (2 per cent, w./v.); mutant organisms showed a different colony type and a faster growth-rate than wild-type organisms. In *GYE* liquid medium parent organisms produced a cellulose pellicle, the medium under the pellicle remaining virtually clear. In contrast, mutant organisms grew diffusely in liquid medium and produced a moderate degree of turbidity. Despite the fact that mutant organisms could be detected in wild-type cultures by the mass-plating procedure, all our attempts to isolate mutants from cellulose-producing cultures by the indirect-selection method of Lederberg and Lederberg[2] have been unsuccessful. The present work was undertaken in an attempt to clarify this contradictory behaviour.

In preliminary experiments (*GYE* medium), made with artificial mixtures of parent and mutant organisms, the parent overgrew the mutant organisms regardless of the age of either culture. Also, mutant organisms failed to produce turbidity when inoculated into parent cultures. Mutant organisms grew well

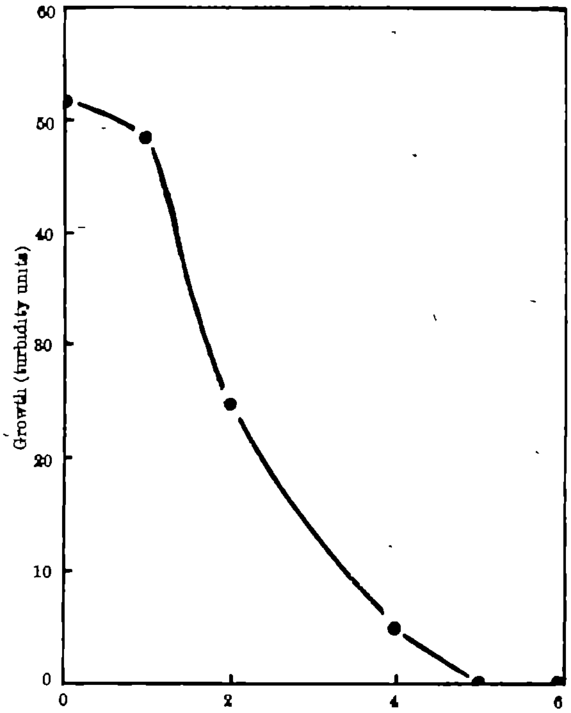

Fig. 1. Growth of mutant organisms in dilutions of filtrate obtained from a culture (6 days) of *Acetobacter acetigenum* NCIB 8132. (Where necessary, the filtrate was made up to a final volume of 6 ml. with *GYE* medium; growth was recorded at 3 days)

when inoculated into Seitz filtrates (*p*H 6·0) of 24 hr. wild-type cultures but not in filtrate of 48 hr., or older, parent cultures even when these were supplemented with glucose and yeast extract. Growth of mutant organisms in various dilutions of wild-type filtrate (6 days) is shown in Fig. 1. The activity of the growth-inhibitory factor was apparently unaffected by heat sterilization (15 lb./sq. in. for 15 min.).

When each of thirteen species of bacteria representing ten genera were tested for their ability to grow in filtrate (*p*H 6·0) of organism NCIB 8132, only the growth of *Proteus vulgaris* was inhibited; a control culture of this organism in *GYE* medium gave good growth. This selective behaviour of the inhibitor was confirmed in several subsequent trials in some of which both glucose and yeast extract were added to the filtrate.

Celluloseless mutants obtained from cellulose-producing cultures of *Acetobacter acetigenum* NCIB 8132 and NCIB 5346, *A. xylinum* NCIB 8034, *A. xylinum* var. *africanum* NCIB 7029 and *Bacterium xylinoides* NCIB 4940 were examined for their ability to grow in the filtrate of their own parent culture and in the filtrate of each other parent culture. The filtrates were obtained from wild-type cultures at six days, were tested at *p*H 6·0, and after inoculation were incubated at 30° for four days. None of the mutant organisms grew in any filtrate except in that of culture NCIB 8034, which supported the growth of all mutant isolates. Each of the wild-type cultures grew well when inoculated into each of the parent filtrates.

It would appear that the production of a growth-inhibitory factor by the cellulose-producing organisms (except culture NCIB 8034) provides a selective environment for their propagation in *GYE* liquid medium. This also offers an explanation for our failure to obtain mutants from culture NCIB 8132 by the method of Lederberg and Lederberg[2]; the colonies (presumably containing both parent and mutant cells), picked from the 'master' plate to *GYE* liquid medium for enrichment of mutants, failed to enrich the mutants because their growth was inhibited. It is further suggested that, when the parent culture is mass-plated, the inhibitory factor is reduced in concentration by diffusion into the agar medium, thus allowing the mutant organism to grow. The growth-inhibitory factor is being studied further.

Ultrastructure of Erythrocytes in Severe Scurvy

A SURVEY of the literature has revealed that anæmia complicates 70 per cent of all clinical cases of severe scurvy[1]. The increased urobilinogenæmia of scurvy is evidence of an accelerated disintegration of erythrocytes[2]. These factors, combined with the recent demonstration of a hæmolytic process in human scorbutic patients[3], prompted us to study the effects of vitamin C deficiency on the ultrastructure of the erythrocytes of animals suffering from scurvy.

Two guinea pigs were made scorbutic by being fed an ascorbic acid-free diet for thirty days, killed and erythrocyte samples obtained from the coronary and femoral arteries and pulmonary capillaries. A

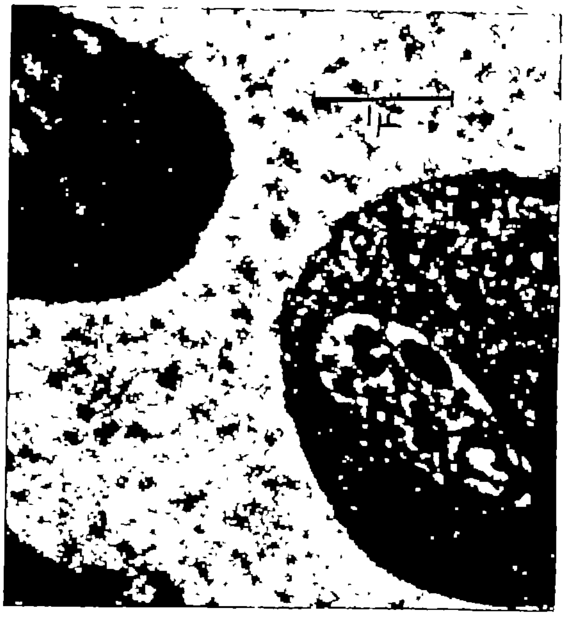

Fig. 1. Two red-blood cells in a capillary—a normal one, left, and a diseased one, right. The latter is slightly granulated. The vacuole contains debris of spherical and filamentous shape. × c. 18,000

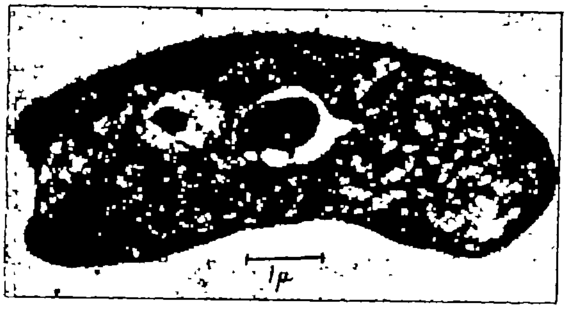

Fig. 2. Diseased erythrocyte as in Fig. 1. Vacuoles with membranes contain particles of different sizes. A chain-like structure exists in one of them. × c. 10,000

part of the cells appeared as if they had holes punched in them. Electron microscope pictures of ultra-thin sections revealed the presence of vacuoles with well-defined borders (membranes) enclosing either whole portions of the red-blood cell or cellular debris in the form of very small circular or ovoid bodies (500–2000 A. in diameter) or filamentous material (Figs. 1 and 2). Parts of these vacuoles do not contain any visible material; the latter is apparently digested and dissolved. The vacuoles increase in size, probably as a result of the hypertonicity of their contents. They finally empty into the surrounding blood stream, leaving behind cellular fragments which may still contain one or more vacuoles and their contents (Fig. 3).

Only a small number of the erythrocytes of two guinea pigs fed the scorbutogenic diet for ten days and two others fed the same diet for twenty days were vacuolated. Such cells were never observed in the blood of the seven control guinea pigs fed normal diets.

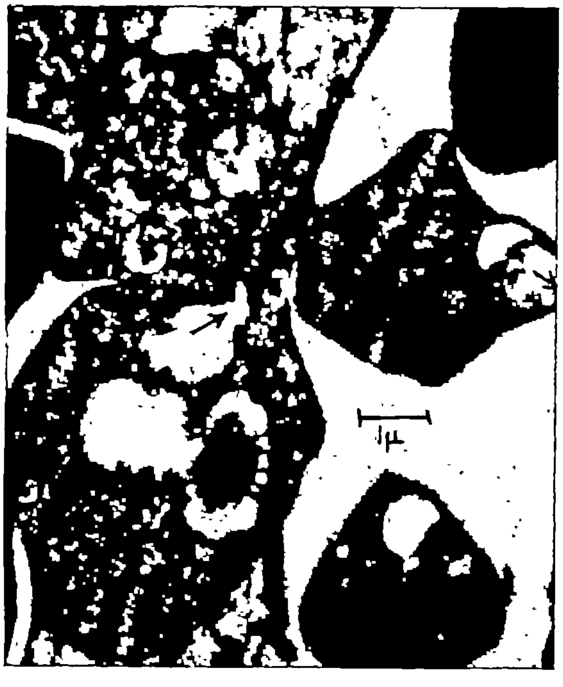

Fig. 3. A group of diseased erythrocytes from the same guinea pig. Some of the vacuoles are very close to the borders of the cell. Arrows point to two places where the vacuoles have burst. × c. 9,000

A more detailed report of these observations will appear in an early issue of *Experimental Medicine and Surgery*.

Sodium, Potassium and Calcium Ions in the Hæmolymph of *Oncopeltus fasciatus* (Dallas)

THE inorganic constituents in the hæmolymph of insects have been investigated in many orders, according to the report of Florkin[1]. There is a dearth of information in the order Hemiptera. Mature adults of this species were used in this investigation.

Eggs were received from R. L. Beard, of the Connecticut Agriculture Experiment Station at New Haven, Connecticut. They were incubated at normal room temperature in deep glass dishes. Their food consisted of dried milk-weed seed and double glass-distilled water. By amputating a leg and antenna the blood was drawn up by capillarity into a micro-pipette. This pipette was graduated to a thousandth of a millilitre. After each bleeding the contents in the pipette were emptied into a 'Vycor' crucible, along with some double glass-distilled water, used to rinse the pipette. This mixture was ashed in a muffle oven at a temperature of 600° C. By pooling the blood of many specimens, samples of 0·1 and 0·5 ml. were tested. The ashed sample was dissolved in 5 ml. of 0·1 *N* hydrochloric acid and this solution was transferred to a small beaker of the Beckman flame photometer. Transmission readings of the sodium, potassium and calcium content were made, after having first adjusted the photometer with standard solution containing known amounts of each ion[2].

These observations on sodium and potassium are the only ones reported for the hæmolymph of *O. fasciatus* (Dallas). The average sodium content was 80·4 mgm. per cent or 39·52 m.eq. per litre. Potassium had a value of 80·2 mgm. per cent or 20·51 m.eq. per litre. The average 11·06 m.eq. per litre for calcium was observed in this experiment. Clark and Craig[3] reported calcium in this species as 13·9 m.eq. per litre. This value for sodium agrees with that obtained for the dipteran larva of *Dictenidia bimaculata* (L.). The potassium value agrees with that obtained in the larva of the lepidopteran, *Celerio* (*Deilephila*) *euphorbiae* (L.), and the pupa of the coleopteran, *Hydrophilus piceus* (L.). Those insects the calcium content of which approximated that found in *O. fasciatus* (Dallas) were the pupa of the silkworm *Bombyx mori* and the adult of *Hydrophilus piceus* (L.)[1].

This project was suggested and supervised by Dr. D. Ludwig.

Quantity of Radioactive Lecithin and Radioactive Cephalin with Lipositol required to produce Sphering of Mammalian Red Cells

THE quantity of distearyl lecithin which has to be added to washed human red cells to produce the disk–sphere transformation has already been described[1]; 10^9 disks require 5–10γ, but how much of the material is adsorbed on the red cell surface is unknown.

Recently we have been able to label lecithin and cephalin plus lipositol with iodine-131, following a method essentially similar to that of Hoffman[2]. The lecithin and cephalin plus lipositol was provided us by the American Lecithin Co. as 'Alcolec Granules', which consist of about one-third lecithin, one-third cephalin, and one-third lipositol. This mixed material was dissolved in ether and brought into contact by shaking with $Na^{131}I$ to which a small drop of nitric acid had been added. After 24 hr., the ether layer was washed four times with potassium iodide and then four times with $Na_2S_2O_3$; it contains all the phospholipids. 20 vols. of acetone was added; a precipitate appears, which is dried in air. On adding ethyl alcohol to the dried material, some of it dissolves (lecithin), while the remainder dissolves on adding diethyl ether (cephalin plus lipositol). Sols of both lecithin and of cephalin plus lipositol were made by adding 1 ml. of the alcohol or ether solution to 9 ml. of saline at 60°, and were cooled slowly to room temperature and filtered.

To 0·5 ml. of a suspension of washed human red cells with a volume concentration of 0·3, that is, each 0·5 ml. containing $1{\cdot}9 \times 10^9$ red cells, 0·5 ml. of the lecithin sol undiluted, diluted 1 in 2, 1 in 4, etc., was added. Similarly, to 0·5 ml. of a similar red cell suspension, 0·5 ml. of the cephalin plus lipositol sol undiluted, diluted 1 in 2, 1 in 4, etc., was added. Control systems contained 0·5 ml. of lecithin sol or of cephalin plus lipositol sol, undiluted or diluted 1 in 2, etc., added to 0·35 ml. of saline. After 15–30 minutes, each system containing red cells was examined by phase optics and between plastic slide and coverslip to see if sphering had occurred. If it had, the radioactivity of 0·5 ml. of the supernatant fluid from the red cell system and 0·5 ml. of the appropriate control was measured in a well-type scintillation counter. After subtracting background, the ratio (count in supernatant of cell suspension)/(count in control) enables one to calculate the minimum fraction of radioactive lecithin or of radioactive cephalin plus lipositol which is attached to the surface of the red cells when they are sphered. To convert this quantity into mgm., about 1 ml. of each of the two sols were weighed before and after drying; the sodium chloride in each was subtracted and the remainder was taken as being lecithin or cephalin plus lipositol.

In the case of both sols, the quantity taken up at the surfaces of the sphered cells was 0·1 ± 0·02 mgm. The relative quantities of lecithin and of cephalin plus lipositol in the human red cell are somewhat uncertain, but taking the values given by Williams, Erickson, Avrin, Bernstein, and Macy[3], lecithin and cephalin are present in about equal amounts, lipositol constitutes a very small fraction, and the total phospholipids in 0·5 ml. of a human red cell suspension of volume concentration 0·3 varies from 0·54 mgm.[4] to 0·44 mgm.[1]. Since an uptake of 0·10 ± 0·02 mgm. of either lecithin or of cephalin plus lipositol is the minimum amount which produces sphering of red cells which contain between 0·54 mgm. and 0·44 mgm. of phospholipids, sphering appears to occur when one out of four or one out of five cell phospholipids had combined with the added sphering agent. This supposes, however, that all the cell phospholipids are equally accessible (as they might be if the phospholipids formed a monolayer at the cell surface); but since there is evidence that at least 50 per cent of the cell lipid is bound to protein as a lipoprotein complex[4], speculation in this direction can be very misleading.

This investigation was made under a grant, *H* 1598, from the U.S. Public Health Service. We have to thank Mr. J. Eichberg, president of the American Lecithin Co., for material and for very helpful advice.

Adrenaline and Failure of Neuromuscular Transmission

IN the course of a study of the effects of adrenaline on neuromuscular transmission, we have observed repeatedly during tetanic stimulation of the rat diaphragm *in vitro* and gracilis *in vivo* failure of transmission of a type which has apparently received little or no attention in the literature. We recorded intracellular end-plate potentials by means of micropipettes filled with 3 *M* potassium chloride, which had an electrical impedance of 10–30 MΩ. When the muscle nerve was stimulated repetitively with supramaximal shocks, the muscle spike potential disappeared as the rate of stimulation increased, leaving only a diminishing end-plate potential. Further increase of frequency, however, did not cause this potential to vanish gradually. Instead, failure of transmission occurred at a point which was evidently *proximal* to the end-plate. This failure was initially intermittent: certain impulses did not reach the end-plate and hence made no impression on the end-plate resting potential (sometimes activity from continuous fibres was seen because of electrical spread).

Impulses which did reach the end-plate gave larger end-plate potentials than before, presumably because

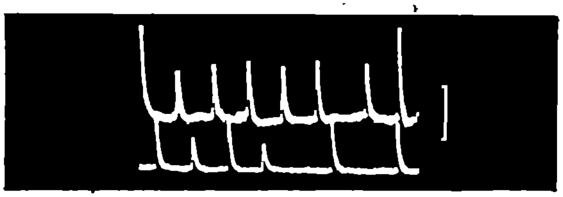

Fig. 1 Potentials recorded intracellularly from two separate end-plates during tetanic stimulation (64/sec.) of only one motor unit in a rat diaphragm, after dissecting a single motor fibre in the phrenic nerve The end-plates show intermittent but asynchronous failure of transmission The voltage calibration at right of figure indicates 5 mV. for upper trace and 15 mV for lower trace

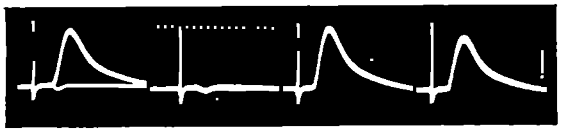

Fig. 2. Photographs of intracellular end-plate potentials from a fibre in a rat diaphragm illustrating the beneficial action of adrenaline on failing neuromuscular transmission The photographs record about twenty superimposed oscilloscopic traces each; they should be read from left to right (1) Intermittent failure of transmission during supramaximal stimulation at 20/sec. (2) Five seconds after the addition of 50 μgm adrenaline hydrochloride to the bathing solution. At this time failure had become complete, but there was some activity in adjacent fibres. Partial recovery began 10 sec. later. Time scale: 1 msec (3) Fifty-five seconds after the injection: there was complete recovery of transmission at 20/sec. (4) Five minutes after the injection Stimulation at 50/sec Vertical scale, 10 mV.

the end-plate was now being stimulated at a lower effective rate. The frequency at which failure began varied considerably with different fibres, with the condition of the muscle, and with the supply of oxygen. The partial block could usually be relieved by lowering the rate of stimulation. In some cases, however, this was not true, and complete, apparently irreversible block ensued. Recording of the activity in the nerve trunk showed that failure of conduction did not take place in the nerve trunk.

In preparations in which a single motor fibre was dissected in the phrenic nerve, the potentials at end-plates of two active muscle fibres did not fail synchronously (Fig. 1). This shows that the failure of transmission was occurring beyond the most distal point of branching of the motor axon, that is, close to or at the nerve ending. We found, both *in vitro* and *in vivo*, that adrenaline (hydrochloride or bitartrate) injected either into the muscle bath (50 μgm. in 30 ml.) or intra-arterially (1–2 μgm.) usually relieved such a partial block (Fig. 2).

Role of Damaged Starch in the Evaluation of Wheat Quality

The introduction of test baking as a means of quality evaluation in the wheat-breeding programme of the Agricultural Research Institute, Wagga, has disclosed a characteristic which does not appear to have been reported in Australian wheats, namely, differential susceptibility of varieties to excessive starch damage during milling. This has been confirmed by microscopic examination with differential staining as used by Jones[1]. Trials by experienced technicians using different experimental mills showed that, with certain wheats, excessive starch damage could not be avoided. In the test-bake, this excessive proportion of damaged starch led to high water absorption, poor loaf volume and crumb texture on the basic test, and 'stickiness' in doughs containing diastatic malt.

The question arose as to why a high proportion of the wheat breeder's cross-breds and some commercial varieties—all of which had been regarded as having superior 'strength' but which did not always perform well under test-baking—should possess this characteristic.

The explanation appeared to lie in the choice of methods previously used for assessing quality. Early selection for quality was based in the first place on the wheat-meal fermentation-time test. With this test the higher water absorption caused by damaged starch leads to a 'tight' dough-ball and consequently a high figure which was interpreted as superior quality. (Incorporation of varying proportions of damaged starch in the dough-balls has confirmed this view.)

Subsequent testing at a more advanced stage in the breeding has been carried out on the farinograph. Trials with flour samples containing increasing proportions of damaged starch (artificially produced) showed that the farinograph revealed no effect due to the additions except an increase in water absorption—a characteristic ordinarily regarded as desirable.

Extensive trials with the Chopin alveograph have shown that a moderate amount of damaged starch manifests itself as enhanced strength and better balance. Only in cases of extreme 'toughness' due to high absorption by damaged starch would one regard the sample as having undesirable characteristics.

If such techniques are to be used in place of test-baking in assessing baking quality of wheats, then it appears imperative that they should be used in conjunction with supplementary tests to show whether the results are an indication of genuine strength, or just 'pseudo-strength' caused by some anomalous characteristic such as excessive starch damage.

Silk Production in the Cheyletidae (Acarina: Arachnida)

While examining some grain infected with tyroglyphid mites, I found a specimen of *Cheletomorpha lepidopterum* Shaw (=*venustissima* Berlese), which had just finished laying eggs. About six eggs were scattered on the ground, and the *Cheletomorpha* was moving backwards and forwards, covering them with a sparse network of silk. In this mite, the mouth is at the end of a gnathosoma, which is shaped like a cone and completely encircles the cheliceral stylets. The silk was coming from the mouth in the form of a very fine thread, which was stretched from side to side over the eggs, the pedipalpal claw being used for manipulating it at times. Unlike *Cheyletus eruditus*

Schrank, which remains crouched over its eggs until the larvæ emerge, the *Chelatomorpha* took no further interest in the welfare of its young, but wandered away to lay a few more eggs in another place.

Silk production is common in the Tetranychidae; but it has not previously been recorded in the Cheyletidae, and it is possible that, in *Chelatomorpha*, part of the salivary gland is modified for this purpose.

Control of Flowering in Rice by Plant-Growth Substances

There is a difference of opinion regarding the presence or absence of florigenic properties of the plant-growth substances. The flowering behaviour of various crop plants as influenced by these substances has been studied by many workers in the field[1-5]. The present investigation aims at studying the effect of various plant-growth substances such as β-indolylacetic acid, α-naphthylacetic acid and 2,3,5-triiodobenzoic acid on the flowering of four different varieties[6] of rice.

Pure grains of the varieties *N*.136 (early), *T*.1145 (early-winter), *T*.141 (mid-winter) and *J*.192 (late-winter) were procured from the Central Rice Research Institute, Cuttack. After a preliminary selection for uniformity, the seeds were soaked in three different concentrations, 500, 250 and 100 p.p.m., of each of the three different plant-growth substances for 72 hr. The grains thus treated were washed thoroughly in water and then sown in seed-bed pots. At the age of 21 days, the seedlings were transplanted to 10-in. earthenware pots containing a mixture of soil and cow-dung manure in the proportion of 8 : 1. The plants were next subjected to weekly foliar spray with the corresponding hormone solution in which the seeds were soaked previously. The spraying was commenced with 28-day-old-seedlings and was continued until the panicles emerged in each plant. Care was taken to maintain uniform soil moisture throughout the experimental period by frequent applications of water.

The criterion of ear emergence was taken as the exsertion of the floral axis through the flag leaf sheath of the main shoot. Observations were taken each day at about 9 a.m. The number of days taken from sowing to ear emergence is presented in Table 1. The results indicate a wide difference among the various varieties in the response to the different treatments. The auxin β-indolylacetic acid had no effect on ear emergence in varieties *N*.136, *T*.1145 and *T*.141, but produced a significant earliness in the variety *J*.192. The auxin α-naphthylacetic acid brought about a significant delay in ear emergence in the early variety *N*.136 and early-winter variety *T*.1145, it had no effect in the mid-winter variety *T*.141, but produced significant earliness in the late-winter variety *J*.192. The so-called anti-auxin 2,3,5-triiodobenzoic acid produced no effect in the varieties *N*.136 and *T*.1145, but brought about earliness in the varieties *T*.141 and *J*.192. Thus the effect of this so-called anti-auxin is in the same direction as the auxins and not opposite to the auxins.

Table 1. Time from Sowing to Ear Emergence in Days (Average of 24 plants)

Sowing date for early variety December 19, 1955; for the other three varieties July 2, 1956

Treatments	Days from sowing to ear emergence			
	Early variety *N*.136	Early-winter variety *T*.1145	Mid-winter variety *T*.141	Late-winter variety *J*.192
β-indolylacetic acid				
500 p.p.m.	84·17	105·46	113·33	120·17
250 ,,	85·77	105·29	112·83	118·96
100 ,,	85·17	105·06	112·42	119·17
α-naphthylacetic acid,				
500 p.p.m.	92·50	107·08	112·58	120·21
250 ,,	87·86	107·25	112·50	119·25
100 ,,	87·20	106·04	112·42	119·50
2,3,5,-triiodobenzoic acid				
500 p.p.m.	83·50	105·42	112·46	119·64
250 ,,	80·10	105·17	112·08	119·83
100 ,,	81·29	105·33	112·17	120·25
Controls	82·29	105·33	113·04	121·00
S.E. Mean	1·04	0·32	0·25	0·27
C.D. at 5 per cent	3·05	0·91	0·69	0·77

One clear result apparent from these studies is that the plant-growth substances in bringing about a modification in floral response have something to do with the normal flowering period of the rice variety. The normal flowering period of a rice variety again is intimately connected with its photoperiodic behaviour[7]. Generally early and medium-early varieties are either long-day or intermediate ones[8,9]; the early-winter, mid-winter and late-winter varieties are predominantly short-day plants[10,11]. The differential behaviour of a plant-growth substance on varieties of rice normally of different flowering durations is exemplified by taking one example. Thus in the present investigation α-naphthylacetic acid brings about a delay in the early and early-winter varieties, is without any effect in the mid-winter variety, while it brings about a significant earliness in the late-winter variety.

The other finding is that the earliness produced in these cases, though statistically significant, is of no agricultural importance. It is sharply in contrast with the results of Sircar and Kundu[12], who found a conspicuous earliness in a late-winter variety 'Rupsail' of Bengal by β-indolylacetic acid and α-naphthylacetic acid.

We are grateful to the Utkal University for award of the M. S. Gajapati Fellowship to one of us (G. S.) and a grant-in-aid from the Jnan Vijnan Parishad Fund, to Prof. B. Samantarai for providing facilities in the Department of Botany, Ravenshaw College, Cuttack, for carrying out this investigation, and to Prof. K. V. Thimann for helpful criticism.

Society of Chemical Industry, Food Group—Nutrition Panel (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Three papers on "The Use of Colourings and Flavourings". (First of four meetings on "Some Nutritional and Allied Problems confronting the Food Manufacturer".)

Thursday, October 24

University of London (at the Institute of Psychiatry, Maudsley Hospital, Denmark Hill, London, S.E.5), at 3 p.m.—Dr. W. H. Thorpe: "Drive and Instinct in Animals".* (Further lecture on October 31).

Linnean Society of London (joint meeting with the Association for the Study of Animal Behaviour, at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Institute of Biology, London Branch (at 41 Queen's Gate, London, S.W.7), at 7.30 p.m.—Prof. P. C. C. Garnham: "Parasite Hunting in Brazil".*

Thursday, October 24—Friday, October 25

Polarographic Society (at the Cora Hotel, Upper Woburn Place, London, W.C.1)—Symposium on "Polarography in Industry".

Friday, October 25

British Psychological Society, Industrial Section (in the Department of Psychology, Birkbeck College, Malet Street, London, W.C.1), at 1 p.m.—Mrs. Eunice Belbin: "Some Experiments in Training Industrial Operatives".

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. S. L. Harris: "Dynamic Loads on the Teeth of Spur Gears".

Royal Institute of Chemistry (at the Manchester Town Hall, Manchester), at 7 p.m.—Dr. J. Bronowski: "Coal and Coal Chemicals in the National Economy" (Tenth Dalton Lecture).

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Mr. Michael W. Perrin: "The Constitution and Aims of the Wellcome Foundation".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Meteorological Officers (5) (under 37, with either a first- or second-class honours degree (or equivalent) in physics, mathematical physics, mathematics or engineering; or a degree (or equivalent) in meteorology) in the Irish Meteorological Service—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (October 25).

Assistant Experimental Officer or Experimental Officer (preferably with a degree or equivalent qualification) to assist in the preparation and analysis of biological samples; radiochemical procedures will be employed—The Secretary, Agricultural Research Council, Cunard Building, 15 Regent Street, London, S.W.1 (October 26).

Lecturer in Physics; and an Assistant, Grade B, in Chemistry—The Principal, Nottingham and District Technical College, Shakespeare Street, Nottingham (October 26).

Assistant Lecturer, Grade B (with good academic qualifications and experience in experimental and theoretical physics), in the Department of Physics—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (October 31)

Fellow in the Department of Biochemistry; and a Fellow in the Department of Physiology, John Curtin School of Medical Research, Australian National University, Canberra—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31).

Lecturer in Organic Chemistry; and a Lecturer in Physical and Inorganic Chemistry at the University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31)

Postdoctoral Research Fellow in the Department of Organic Chemistry, for research which includes studies on the oxidation of phenols and investigations into the structure of complex paint phenolics—The Registrar, The University, Liverpool (October 31).

Reader in Applied Mathematics; an Assistant Lecturer (Grade B) in Pure Mathematics; and an Assistant Lecturer (Grade B) in Applied Mathematics—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (October 31).

Senior Lecturer or Lecturer in the Department of Physics, Canterbury University College, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, October 31).

Senior Lecturer (with high academic qualifications and/or professional qualifications, some teaching experience, and preferably industrial experience) in Chemical Engineering at Neath Technical College—The Director of Education, County Hall, Cardiff (October 31).

Lecturer in Biochemistry—The Secretary, The Queen's University of Belfast, Belfast, Northern Ireland (November 1).

Senior Lecturer or Lecturer (Grade I) in Physics, and a Lecturer (Grade II) in Physics at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 1).

Lecturer or Assistant (Grade B) (with an honours degree) in Pharmacology—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.1 (November 2).

Physical Chemists (with an honours degree or equivalent and experience in corrosion or a related field) at the Research Laboratories, Leatherhead, Surrey, for work on corrosion problems arising in nuclear and conventional power stations—The Director of Establishments, Central Electricity Authority, Winsley Street, London, W.1, quoting Ref. N/432 (November 2).

Senior Scientific Officer (Chemist) (with a first- or second-class honours degree or equivalent in an appropriate subject, wide experience of modern analytical techniques and experience in the use of radioactive tracers) in the Department of Scientific and Industrial Research, Research Group, Harwell, for work on radio-isotope application problems—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. F 539/7A (November 2).

Physicists and Metallurgists (with at least a second-class honours degree in physics or metallurgy or equivalent qualifications, and some postgraduate experience) in the Research and Development Branch of the Industrial Group of the U.K.A.E.A. at Culcheth Laboratories, Culcheth, Warrington, Lancs, to lead an intensified effort into the metallurgical and physical metallurgical problems of nuclear power—The Recruitment Officer, United Kingdom Atomic Energy Authority, Industrial Group Headquarters, Risley, Warrington, Lancashire, quoting Ref. 2094 (November 4).

Senior Laboratory Steward (with experience in the physics department of a university) in the Department of Physics, University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 6).

Lecturers (2) (preferably with an interest in geophysics) in Physics at the University College of Ghana—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 12).

Assistant Conservators of Forests (3) (with a thorough knowledge of forestry, an appropriate university degree, and preferably experience in practical forestry and botany) in the Forests Department, Ministry of Agriculture, Republic of the Sudan—The Sudan Embassy, Personnel Section, Cleveland Row, London, S.W.1, quoting Ref. "Assistant Conservator Forests 4/436" (November 15).

Assistant Lecturer in Geography at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, November 15).

Lecturer in Social Anthropology at Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, November 15).

Senior Lecturer or Lecturer in Chemistry at the University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 15).

Chair of Pathology tenable at St. Thomas's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (November 18).

Senior Principal Scientific Officer, to co-ordinate the work of the Plant Pathology and Entomology Departments, particularly in the field of virus diseases—The Secretary, Glasshouse Crops Research Institute, Worthing Road, Rustington, Littlehampton, Sussex (November 20).

Chair of Archæology—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (November 23).

Lecturer in Zoology at Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, November 30).

Research Assistant (with a university degree in chemistry and experience of research work in biochemistry or organic chemistry) at the St. Vincents School of Medical Research, Melbourne, N.6, for a research programme in the field of protein chemistry, under the direction of Dr. Pehr Edman—The Chief Executive Officer and Secretary, St. Vincent's Hospital, Victoria Parade, Fitzroy, N.6, Victoria, Australia (December 31).

Assistant Lecturer (physics graduate), to assist with the development of the new four-year Sandwich Course in Food Technology—The Principal, National College of Food Technology, Cranwood Street, City Road, London, E.C.1.

Chemist (with a degree or equivalent, varied experience in industry, and a knowledge of resins and their changing applications), to be responsible for answering inquiries of a chemical nature; the assessment of natural resources; and encouraging the development of new industrial projects—The Chief Executive Officer, The Scottish Council (Development and Industry), 1 Castle Street, Edinburgh 2.

Editorial Assistant (with a degree in mathematics or physics and some editorial and/or library experience) to undertake work in connexion with the publications of the Physical Society, and also to take charge of the Society's library—The Secretary-Editor, The Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7.

Lecturer, and an Assistant Lecturer, Grade B (with a good honours degree, together with teaching, research or industrial experience), in the Department of Applied Physics—The Clerk to the Governors, Welsh College of Advanced Technology, Cathays Park, Cardiff.

Lecturers, Grade IIa (honours graduates), in the Physics and Mathematics Departments—The Principal, Paisley Technical College, George Street, Paisley, Renfrewshire.

Research Assistant (preferably with some knowledge of, and interest in, protein chemistry), for research on plasma protease—The Pathologist, Institute of Orthopædics, Royal National Orthopædic Hospital, Brockley Hill, Stanmore, Middlesex.

Research Assistant (with a degree in zoology and interested in the development of cytological and/or physiological techniques) in the Department of Zoology—The Registrar, The University, Nottingham.

Research Fellow and a Research Scholar in the Department of Chemistry, for work on organo-silicon compounds—The Registrar, The University, Leicester.

Research Officer (Botany) (with a first- or second-class honours degree in botany, with some experience of research and a special interest in ecology and/or plant physiology) in the Department of Forest Research, Federation of Nigeria, to investigate the physiological factors influencing seed germination and seedling development of trees in Nigerian forests, entailing field studies as well as experimental work under controlled environmental conditions; and to undertake the general duties of a research officer—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD/61/14/09.

Scientific Officer (with a first- or second-class honours degree in bacteriology or microbiology, or a first- or second-class honours degree which included chemistry and biology, followed by a post-graduate diploma in bacteriology) at the Water Pollution Research Laboratory (D.S.I.R.), Stevenage, for research on bacteriological problems connected with the treatment of sewage and trade wastes, and pollution of rivers—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting G.180/7A.

Scientific Officer (with a first- or second-class honours degree in physics or equivalent), to carry out the investigation of a method for producing large short pulses of neutrons—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref. 1598/34.

AMENITIES, RIGHTS OF THE INDIVIDUAL AND THE NEEDS OF DEVELOPMENT

On November 1, 1955, a Committee on Administrative Tribunals and Enquiries was appointed under the chairmanship of Sir Oliver Franks, "to consider and make recommendations on: (*a*) the constitution and working of tribunals other than the ordinary courts of law, constituted under any Act of Parliament by a Minister of the Crown or for the purposes of a Minister's functions; (*b*) the working of such administrative procedures as include the holding of an inquiry or hearing by or on behalf of a Minister on an appeal or as the result of objections or representations, and in particular the procedure for the compulsory purchase of land". Its inquiry thus involved the consideration of an important aspect of the relation between individual and authority, a relation which is not static, but requires adjustment from time to time if a reasonable balance is to be held between private right and public advantage, between efficiency of administration and fair play for the individual. Its bearing on efficient administration should of itself make the report of interest to the scientist as such; but its clear and trenchant exposition of what is involved and the principles which should determine both procedure and practice concerns him closely as a citizen. Nor need we look further than to the difficulties and opposition which have occurred in connexion with the Atomic Energy Authority's plans for nuclear power stations or its new research station at Winfrith Heath, or the many recent proposals to place such a station in the Snowdonia National Park and for an oil refinery at Milford Haven, in the Pembrokeshire National Park, to realize that procedure for the acquisition and use of land touches technical development and the utilization of the natural resources of Britain as well as the rights and needs of the individual citizen very closely indeed.

What the Franks Committee's report* has to say on the procedures by which the rights of individual citizens can be harmonized with wider public interest bears closely on this wider question of the reconciliation of the claims of varying public interests, of those of amenity, defence, water and power supply, forestry, agriculture, mineral resources and the like. The continued expansion of government activities and responsibilities, often enough as a result of technological development, has, in the past quarter of a century, since the Donoughmore Committee reported on Ministers' Powers in 1932, led to the establishment of many new tribunals and the extension of the activities of old ones, while far greater use is made of the powers to acquire land and control its use. Nor is any dissent likely from the conviction of the Franks Committee that tribunals as a system for adjudication have come to stay, and that the tendency for issues arising from legislative schemes to be referred to special tribunals is likely to grow rather than to diminish.

In such circumstances it is important, if not essential, that the issues should be clearly understood by the individual citizen. The Franks Committee points out that at the preliminary stage the most important requirement is that the citizen should be aware of and fully understand his right to apply to a tribunal. Later, it insists that fairness requires that those whose individual interests are likely to be affected adversely by the action proposed should know in good time before the inquiry the case which they will have to meet, and clearly this should apply equally to other public interests which may be affected. The Franks Committee was not satisfied that this requirement is always fully met, and it recommends various statutory changes in procedure in consequence. Likewise, it recommends that wherever possible some statement of the ministerial policy relevant to the particular case should also be available before the inquiry.

The recommendations that, unless the Minister has special reasons to the contrary, a public inquiry should be held in preference to a private hearing in connexion with the compulsory acquisition of land, development plans, planning appeals and clearance schemes, that the full text of an inspector's report should accompany the Minister's letter of decision and be available on request, and that the Minister's letter of decision should set out in full his findings and inferences of fact and the reasons for the decision, illustrate further the importance which the Committee attaches to this question of publicity. Lord Silkin does indeed dissent from the recommendation that reports of inspectors should be published, and the report itself sets forth some weighty arguments against publication, particularly in regard to the effect on frankness and on the relation between Ministers and their advisers. It is clearly a matter for judgment here as to which course is most in the public interest, but none the less the weight attached to publicity in general is not affected.

On that ground alone—all special considerations of scientific interest apart—it is important that the Franks report should be widely read and its statement and analysis of the issues clearly understood. As the committee points out at the outset, in Great Britain government rests fundamentally upon the consent of the governed, and the general acceptability of its adjudications is a vital element in sustaining that consent, as it is in securing that administration is efficient both in ensuring that the objectives of policy are securely attained without delay and in satisfying the general body of citizens that it is proceeding with reasonable regard to the balance between the public interest which it promotes and the private

---

(or other public) interest which it disturbs. It could not be pretended that either requirement has been well served in the proposals for the new power stations at Trawsfynydd and Hunterston, for example.

The essential characteristics of these special procedures should be, the Committee suggests, openness, fairness and impartiality, though these characteristics need not necessarily be present in the same way and to the same extent at all stages: the Minister, for example, is committed to a policy which he is charged by Parliament to execute and, in this sense, he is not—and cannot be—impartial in his decision on an inquiry. The rule of law, however, stands for the view that decisions should be made by the application of known principles or laws, and in general such decisions will be predictable. On the other hand, a decision may have to be taken without principle and without any rules, and the Committee observes that methods of adjudication by tribunals are not in general the same as those of adjudication by Ministers; and where it is desirable to preserve flexibility of decision in the pursuance of public policy, a wise expediency is the proper basis of right adjudication and the decision must be left with a Minister. While, however, tribunals in their cheapness, accessibility, freedom from technicality, expedition, and expert knowledge of their particular subject, possess advantages over the courts, the Franks Committee, as a matter of general principle, is firmly of the opinion that a decision should be entrusted to a court rather than to a tribunal in the absence of special considerations which make a tribunal more suitable, and no less firmly it insists that all decisions of tribunals shall be subject to review by the courts on points of law.

The Committee is satisfied that, in general, despite the haphazard way in which tribunals have developed, the method of decision by tribunals works reasonably well, and in considering what improvements and safeguards could be introduced into the present structure it remarks that openness appears to require publicity of proceedings and knowledge of the essential reasoning underlying the decisions; fairness to require the adoption of a clear procedure which enables parties to know their rights, to present their case fully, and to know the case which they have to meet; and impartiality to require the freedom of tribunals from the influence, real or apparent, of government departments concerned with the subject-matter of the decisions. In this last consideration we have to recognize the principle that neither individual nor department should be judge in his own cause, disregard of which has bedevilled questions of the use of land for almost two decades, and the Franks Committee itself, while satisfied that the requirement of fairness, to the importance of which much of the evidence submitted directed attention, was generally met, were not so satisfied that it held with some hearings before county agricultural executive committees. This appears to be due largely to the exercise by those committees of adjudicating functions in addition to their executive functions. This practice is regarded by the Franks Committee as wholly undesirable: while it exists, the parties cannot feel that their case will receive a fair hearing and be impartially decided. Furthermore, save in time of emergency or threat of emergency, it recommends that the Service departments should be required to adopt the same procedure for the acquisition of land as may be prescribed for other government departments, except where the appropriate Service Minister or his most senior official personally certifies dispensation on grounds of security in a particular instance.

As regards appeal to the courts, whatever procedure is devised—and it may well differ for different tribunals—it should be simple, cheap and expeditious. In the first instance, it should appropriately be to an appellate tribunal, followed, as already indicated, by an appeal to the courts on points of law. Nor is the Committee opposed to amalgamation of tribunals, though it rejects specific proposals made to them and recommends that whenever establishment of a new tribunal is proposed the possibility of vesting the jurisdiction in an existing tribunal should first be considered.

It is more critical of administrative procedures for the acquisition of land, and points out that these cannot be classified as purely administrative or purely judicial. The provision for a special procedure preliminary to the decision involves testing an issue often partly in public, and the final decision cannot be reached by the application of rules and must allow the exercise of a wide discretion in balancing public and private interest. Criticism of particular instances over the past decade and more has repeatedly turned on the failure or apparent failure to balance those interests and still more to balance rival public interests.

If the administrative view is dominant, the public inquiry cannot play its full part, and the rights and interests of individual citizens affected or other public interests may not be sufficiently protected, nor, save exceptionally, can Parliament provide such protection. The Franks Committee endorses the view that Parliament has neither the time nor the knowledge to supervise the Minister and to call him to account for his administrative decisions. On the other hand, the judicial view overlooks the fact that the Minister himself, who is responsible to Parliament for the ultimate decision, cannot conduct the inquiry in person.

In seeking a reasonable balance between the conflicting interests, which include, besides the responsibilities of Ministers and other administrative authorities and the rights and feelings of individual citizens affected, the public interest that Ministers and authorities should not be frustrated in executing their duties and that their decisions should be subject to effective checks or controls, the Franks Committee notes that dissatisfaction with procedures relating to land arises largely from the basis of compensation. Objections to compulsory purchase would be far fewer if compensation were always assessed at not less than market values. This consideration lay outside the Committee's terms of reference, but it bears closely on the question of public confidence. It reiterates, in conclusion, that even if administrative procedures are changed and made as open as possible in the way suggested, public confidence will not be maintained, nor complete satisfaction given to those affected, if the basis of compensation is not regarded by them as reasonable.

There is a further important point. Wisely, the Committee emphasizes that no recommendation it can make will compensate for a wrong approach to administrative activity by the official concerned. It believes that there would be less public resentment against administrative action if all officials were trained in the principle that the individual has the right to enjoy his property without administrative interference unless that interference is unmistakably justified in the public interest. The attitude of an owner or occupier may well turn on whether he receives reasonable and courteous notice of a proposal to inspect the land.

The Franks report cannot be properly described as of scientific interest in the strict sense of the word. Nevertheless, it is of particular interest to the scientist both because its recommendations relate to the conditions which promote efficient administration and because so often the procedures described have been necessitated by technological development. The scientist, too, especially in view of his increasing responsibility for administration both in industry and in public affairs, might well pause to reflect on the principles so clearly enunciated in this fresh statement of the relations between individual rights and public interests, and how far those essential features of openness, fairness, impartiality—and courtesy—might not be applied in his own sphere of service and professional relations. With the growing complexity of administration and the multiplicity of technical issues in public life, it is increasingly essential that the channels of assent should be deeply dug.

CRYSTALLOCHEMICAL ANALYSIS

The Barker Index of Crystals

A Method for the Identification of Crystalline Substances. By Dr. M. W. Porter and R. C. Spiller. Vol. 2: Crystals of the Monoclinic System. Part 1: Introduction and Tables. Pp. v+383. Part 2: Crystal Descriptions—M.1 to M.1800. Pp. viii+760. Part 3: Crystal Descriptions—M.1801 to M.3572. Pp. viii+688. (Cambridge: W. Heffer and Sons, Ltd., 1956. Published for the Barker Index Committee.) £10 net the three parts.

CRYSTALLOCHEMICAL analysis aims at the identification of crystalline substances from measurements of their interfacial angles. The special advantages of this method lie in the ease and comparative speed with which even substances of highly complicated chemical composition can be identified by a procedure during which none of the material is consumed and also in the very small amount of material necessary.

In order that characteristic angles may be listed in numerical order, a standard setting and orientation must be selected for each substance. Apart from an early attempt by M. L. Frankenheim, systematization of data in this manner was first achieved by the work of E. S. Fedorov and his associates. His great work, "Das Krystallreich; Tabellen zur krystallochemischen Analyse", published in 1920, listed some 7,400 substances, of which 6,800 could be regarded as satisfactorily described. T. V. Barker, of Oxford, after spending a year under P. Groth at Munich, went on to work in Fedorov's laboratory and helped in the production of the "Tabellen". Extensive trials of the Fedorov method, however, ultimately convinced him that it was unlikely to acquire general acceptance as the basis for a practicable method of crystallochemical analysis. In his "Systematic Crystallography: an Essay on Crystal Description, Classification and Identification", published in 1930, he put forward a new scheme which was purely descriptive. Founding his choice of setting largely on the principle of simplest possible face-indices, by which a maximum of thirteen pairs of parallel faces may be given indices involving only the figures 0, 1 and $\bar{1}$, he abandoned the 'ideal', 'hypohexagonal', 'trigonaloid' and 'tetragonaloid' groups, set up by Fedorov partly on theoretical considerations, and used instead the orthodox crystal systems. Specimens of the kind of classification tables envisaged were given, but re-calculation of the data for about 8,000 non-cubic substances was a heavy task for an individual. Barker himself had only limited time available for scientific work after taking up an administrative post at Oxford, and he died in 1931. A number of crystallographers at Oxford, convinced that Barker's scheme was a great improvement on that of Fedorov and that it could be made the basis of a practicable crystallochemical index, arranged to press forward with the calculations and tabulation. The work was co-ordinated by a committee under the chairmanship of A. E. J. Vickers; valuable help was given by a group of Dutch crystallographers, working at the University of Groningen under P. Terpstra, and by individuals. Vol. 1, published in 1951, included the appropriate introductory matter and an index and descriptions of crystals of the tetragonal, hexagonal, trigonal and orthorhombic systems.

Vol. 2, now under review, brings the task measurably nearer completion. Concerned as it is with the monoclinic system, the 3,572 substances in this volume represent about one-half of the crystals to be described, and this proportion is reflected in the bulk of the three large parts into which the volume is divided. The arrangement follows closely that of Vol. 1. Part 1 begins with a 40-page introduction, by M. H. Hey, to the application of the Barker method to monoclinic crystals. Nineteen examples, worked through in some detail, are all organic substances chosen to illustrate various points of possible difficulty. The main classification angle used in the monoclinic system is *am*, between the faces (100) and (110), but a short auxiliary table lists also angles *ca*, between the faces (001) and (100), for a number of incompletely developed crystals. Other tables list the substances according to refractive indices (in order of β-index), densities and melting points (simple physical tests are often useful for confirmation of a crystallographic determination). There are also lists of English chemical and mineralogical names and (an innovation since Vol. 1) of German names used by Groth in his "Chemische Krystallographie". A new feature also is a page of "Brief Directions" for the experienced crystallographer, a copy of which can be obtained for insertion in Vol. 1.

Parts 2 and 3 of Vol. 2 contain the 3,572 crystal descriptions. These parts, and the tabular matter of Part 1, have been reproduced from typescript by offset litho. As in Part 2 of Vol. 1, references are given under each substance to a standard chemical or mineralogical work as well as to Groth; some 125 substances not described by him are appended to Part 3. The descriptions include the matrix necessary to transform Groth's setting to the appropriate Barker setting, physical constants (including optical properties) and, where available, the spacings of the three strongest lines in powder photographs as given in the A.S.T.M. Index. During compilation it has been possible to correct a large number of errors, mainly in the calculations by original authors, which have been detected in Groth's descriptions. Quite aside from their use for purposes of identification, these two parts, together with Part 2 of Vol. 1, thus form a valuable compendium of up-to-date and accurate crystallographic information. Vol. 3 (dealing with crystals of the anorthic (triclinic) system) is in preparation. Its publication will complete an addition to crystallographic literature on which the committee and the editors are to be warmly congratulated.

F. C. PHILLIPS

ATOMIC STRUCTURES

The Calculation of Atomic Structures

By Prof. Douglas R. Hartree. (Based on lectures given under the auspices of the William Pyle Philips Fund of Haverford College, 1955.) (Structure of Matter Series.) Pp. xiii+181. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1957.) 40*s*. net.

THIS book provides a simple account of methods used in calculations of atomic spectra. It has more the character of a guide to the subject rather than of an introduction, and is evidently intended for the specialist in a related field who becomes involved in atomic spectroscopy as an adjunct to his own work. It would also be of considerable value to the experimental spectroscopist who may be averse to advanced mathematics. The reader is assumed to have only an elementary knowledge of mathematics and quantum theory, although he must be reasonably familiar with descriptive or experimental atomic spectroscopy, and if he is to make full use of the book he must not have an aversion to tables of functions.

There are several drawbacks to this elementary approach which make the book less satisfactory as an introduction than as a guide to the subject. The principal one is that it has forced the author to describe mainly the methods which were used during the earlier development of calculations on atomic spectra, rather than the more powerful and elegant methods which were developed later but which involve more difficult mathematics; in particular, the work of Racah is mentioned only in a passing reference. Throughout, the author concentrates his attention on the methods of calculation rather than the general theory behind the methods; for the budding theoretical physicist this is very much putting the cart before the horse, but there is no doubt that Prof. Hartree's consideration will be appreciated by others less mathematically inclined.

The first chapter introduces Schrödinger's equation for an electron in a central field, discusses the separable wave function approximation for a many-electron system and outlines the idea of the self-consistent field which was introduced by the author in 1927 and which forms the basis of all methods of computing atomic spectra. The second and third chapters describe the variation method for obtaining the energy of a quantum system, illustrating it by an application to helium and then to a many-electron system. The variation method is related to the Fock equations and the Hartree equations, and it is shown how the use of determinantal wave functions reduces the problem to the calculation of certain types of integral.

Chapter 4 gives a brief description of the elements of numerical methods, quoting formulæ without proof but with readily accessible references. The application of these methods to the solution of the equations for the energy of an atom with a complete group of electrons is described in the next chapter, and in Chapter 6 this is extended to atoms with incomplete groups of electrons. Methods of interpolation which are of use in guessing trial wave functions are discussed in Chapter 7.

The remaining Chapters 8, 9 and 10 deal somewhat briefly with more advanced topics concerning the energy differences of different states of ionization (Chapter 8), the use of the Dirac equation for the electron (Chapter 9), and recent improvements on the self-consistent field method of approximation.

R. J. EDEN

STEREOCHEMISTRY

Steric Effects in Organic Chemistry

Edited by Melvin S. Newman. Pp. vii+710. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1956.) 100*s*. net.

IN the early development of electronic theories of organic chemistry, much attention was focused on the influence of the polar effects of substituents on reactivity. To-day, now that this aspect of the subject has become extensively documented, increasingly more attention is being paid to stereochemical factors as they affect reaction-paths and mechanisms. Here must be considered not only bulk effects of substituents on the energy and entropy of activation, but also their effects in obstructing or enhancing the conjugative power of other substituents, the effects of varying the spatial relationships within the reacting molecule, and even the stereo-electronic considerations which determine whether bonds of particular types will be formed between pairs of atoms, and how strong these bonds will be.

Indeed, considering that organic reactivities are determined by the exact geometrical requirements and relationships of initial and transition states, a monograph on steric effects in organic chemistry has a very wide field to encompass. It is not surprising, therefore, that the work under review should be rather uneven in its coverage. In a number of chapters, equilibria and properties of ground-states of molecules are discussed; as in W. G. Dauben and K. S. Pitzer's account of conformational analysis; G. S. Hammond's discussion of equilibria between acids and bases and in tautomeric systems; M. S. Newman's description of molecular complexes and molecular asymmetry; and L. L. Ingraham's account of steric effects on spectra and related properties. Other chapters deal more specifically with problems of relative reactivities. A particularly welcome and authoritative discussion of the calculation of the magnitude of steric effects is given by F. H. Westheimer. Substitution at a saturated carbon atom is described by E. L. Eliel; G. S. Hammond and M. F. Hawthorne discuss steric effects in aromatic substitution; and D. J. Cram gives accounts of intramolecular rearrangements and of olefin-forming elimination reactions. Cleavage of the carbon–carbon bond is described by H. H. Wasserman, and steric effects among the common organo-metallic compounds by G. F. Wright. M. S. Newman contributes a chapter on additions to unsaturated systems, and R. W. Taft discusses attempts to separate polar, steric and resonance effects on reactivity.

The contributors are all active in research, and have special interests in the fields which they cover. This adds to the interest and value of the work. Prof. Newman is to be congratulated and thanked for editing such an excellent volume. As a general criticism, it might be maintained that the American point of view is, in some chapters at least, promulgated with less than adequate judgment; but it is a book which will be of value to everyone interested in organic chemical reactivity. It is well indexed and well printed; its price will ensure that most chemists in Britain will consult it, when they need to, in their nearest library. P. B. D. de la Mare

DOUBLE MEANINGS

Digital Calculating Machines and their Application to Scientific and Engineering Work

By G. A. Montgomerie. Pp. viii + 262. (London and Glasgow: Blackie and Son, Ltd., 1956.) 30s. net.

The Management Approach to Electronic Digital Computers

By J. Sandford Smith. Pp. xi + 227. (London: Macdonald and Evans, Ltd., 1957.) 35s.

Neither of these books achieves a very profound level of treatment of its respective subject, and they are, to a certain extent, complementary in their approach both as to the machines themselves and to the applications which are considered. G. A. Montgomerie's book is almost exclusively concerned with relatively simple devices of the desk-calculator variety, while that of J. Sandford Smith dismisses these useful tools in a few preliminary pages and then proceeds to a consideration of the newer electronic machines.

The prose style of both authors is good, but, whereas Sandford Smith nowhere descends to abstruse questions of notation and definition, Montgomerie attempts, in his introductory chapters, an obscure method of symbolizing digital operations which is likely to repel many readers.

A useful feature of both books is the attempt which is made to summarize the characteristics of available machines and to point out the way in which these may influence the prospective user in his choice, and although it may be argued that a short practical trial is worth any amount of verbal description, this is not always possible, especially with the large machines.

Montgomerie's book is divided into twelve chapters. The first is introductory, the next two deal with adding machines, and Chapters 4–7 are concerned with machines which can multiply and divide. Then follow a chapter on numerical analysis and two on punched card machines and special purpose machines respectively. The remaining Chapters (10–12) describe automatic digital calculators and programming. Major faults are the extremely superficial chapters on numerical analysis and on special purpose machines. In the former the Newton–Raphson method for evaluating square roots is illustrated by a ponderous numerical example, but the author does not seem to think it worthy of mention that the process is an error-squaring one. The title of the book indicates that scientific and engineering applications are covered; but their only real mention occurs in Chapter 9, where the highly atypical Beevers–McEwan Fourier synthesizer occupies most of the space.

Sandford Smith's book has seventeen chapters, two appendixes, a bibliography and a glossary. After two introductory chapters, Chapters 3–8 discuss the units of a computer, 9 and 10 programming and checking, 11–13 the approach of the business executive to the acquisition of a machine. Then follows a chapter describing the available British machines, and the book concludes with essays on the impact of automation on the auditor and the worker. The first appendix contains an extract from the amusing "Rambles through Binland" by Michaelson and the second an account of the clerical operations involved in such things as agriculture, mining and building. There is little to criticize in the book, which (unless it is merely in the mind of the reviewer) must surely be unique in presenting a mathematical diagram (p. 97) which contains a dubious joke.

Both books are well written and reasonably priced: though neither can be described as authoritative they will doubtless find a wide circle of readers.

A. D. Booth

SOLID SYSTEMS IN CHEMICAL ENGINEERING

Chemical Engineering Practice

Edited by Herbert W. Cremer and Trefor Davies. Vol. 3: Solid Systems. Pp. vi + 534 + xviii. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1957.) 95s.

The third volume in the series "Chemical Engineering Practice" is devoted to solid systems. The main subjects discussed in the first section are crushing, grinding and methods of analysing the size of solid particles. The second section covers screening, grading and classifying, in which are included flotation, sedimentation, coal-washing and air-flow selection. There are then two chapters on the mixing of solids, and on the storage and handling of solid material. The final section of this volume contains two chapters on gas cleaning with cyclones and electro-precipitation.

These are subjects in which, in general, the main designs of equipment have come from prolonged practical experience rather than from the logical application of physical concepts. While the modern ideas of chemical engineering science are indicating some of the important fundamentals in these processes as, for example, in the mixing of solids and the settling of particles, it is not yet possible to make an entirely satisfactory design simply by using these physical concepts, and sound practical experience is essential in specifying equipment.

Dr. Heywood has given a short and clear account of the principles of crushing and size analysis, but the recent work of Bond and Rose might well have received greater emphasis. Messrs. Farrant and North have given a splendid account of crushing and grinding equipment, including practical data on the performance of machines.

All the chapters are written by men with wide experience of the industry, and they have given us valuable results arising from their work. Each chapter contains an account of the theoretical principles as at present understood, but the main emphasis is on the performance and use of existing equipment. Mr. Forbes Stewart has introduced two simple calculations on the design of sedimentation equipment and more illustrations of this kind would be welcome. Examples of methods used by practical men in design are always to be encouraged.

We are given results of the experience of those who have worked for many years in the various fields, and we must be indebted to them and to Mr. Cremer and Mr. Davies for providing this information. It is clear that in this area of chemical engineering there is a considerable amount of research and development to be done before the physical concepts are fully established and can be applied in a quantitative manner.

This book is well presented and will be welcomed by a large number of practising engineers.

J. M. COULSON

VECTOR ANALYSIS

Vector Analysis

By Prof. Louis Brand. Pp. xiv + 282. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1957.) 48s. net.

IN this book the subject is carried as far as is required by a course of first-degree level, the treatment being rather more elementary than in the author's "Vector and Tensor Analysis".

Starting with a vector as a directed line segment, the rules of vector algebra are developed in Chapter 1, including the various products and the use of reciprocal bases. The examples include vector proofs of geometrical theorems such as Desargues's theorem as well as the more usual applications to planes and straight lines.

After a short chapter on line vectors (that is, vectors localized in a line), and statics, we have three chapters in which variable vectors, differentiation and integration are developed. Chapter 3 on functions of one variable includes the curvature and torsion formulæ, velocities, accelerations and kinematics of a rigid body.

Chapter 4, differential invariants, includes a brief discussion of dyads and dyadics, and the divergence and rotation of a vector point function are obtained as the invariants of its gradient dyadic. This enables some results in this and the following chapter on integral theorems to be obtained more neatly. These two chapters cover the standard theorems in vector calculus of Gauss, Green and Stokes, with some discussion of solenoidal and irrotational vector fields. Formulæ are derived in general orthogonal co-ordinates, but the examples are limited to polar and cylindrical co-ordinates.

A rather elementary chapter on dynamics is then followed by one on fluid mechanics and one on electrodynamics in which the application of the theory is illustrated. The electrical theory is developed from Maxwell's equations, rationalized M.K.S. units being assumed. A short paragraph on units and dimensions is included, and an appendix lists the names and dimensions of the various units.

In the last chapter the reader is brought back to abstract theory with an introduction to vector spaces.

The book is well produced. The writing is clear and simple, and the theory is illustrated by many examples. In fact, it can be recommended without reservation.

A. W. GILLIES

INTERNATIONAL ASTRONOMY

Transactions of the International Astronomical Union

Edited by P. Th. Oosterhoff. Vol. 9: Ninth General Assembly held at Dublin, 29 August to 5 September 1955. Pp. ix + 802. (Cambridge: At the University Press, 1957.) 80s. net.

THIS volume is devoted for the most part to the proceedings of the meetings of the International Astronomical Union at Dublin in 1955. There are reports and discussions of some forty commissions and of about half that number of sub-commissions. A very wide range of work is covered and the reports themselves also vary a great deal, from brief summaries and recommendations to long critical surveys of recent research, complete with bibliographies. In addition there are accounts of four joint discussions, in each of which several commissions took part, dealing respectively with solar flares, photoelectric image tubes, fundamental stars (for positional measures), and turbulence in stellar atmospheres. The proceedings of three more elaborate symposia, on non-stable stars, radio astronomy, and a comparison of the large-scale structure of the galactic system with that of other stellar systems, are to be published separately. The first of these, in fact, has already appeared.

The International Astronomical Union is one of the oldest and most successful of the international unions. This is not to say, however, that its members are completely satisfied. Rather drastic steps are now being taken to change the commissions, some of which have in recent years become altogether too big and unwieldy, into much smaller and more compact groups. Further, the general growth in membership has led to some loss of the close personal contact and interchange of ideas which were such a happy feature of early meetings of the Astronomical Union and of the Solar Union before it. To meet this difficulty, quite small discussion meetings on special topics are now being organized outside the General Assembly, and these so far have proved very successful.

One part or another of these Transactions will be essential reading for every active astronomer, even if relatively few go through the whole volume. Any other scientist who wishes to get a fairly accurate idea of what modern astronomy is—neither old-fashioned routine on the observational side, nor irresponsible speculation on the theoretical—would do well to take a serious look at this book.

R. O. REDMAN

CULTIVATION OF EMBRYONIC CHICK BONES ON CHEMICALLY DEFINED MEDIA

By Dr. J. D. BIGGERS
Strangeways Research Laboratory, Cambridge, and Department of Physiology,
Royal Veterinary College, London, N.W.1

Dr. M. WEBB
Strangeways Research Laboratory, Cambridge

AND

Dr. RAYMOND C. PARKER and GEORGE M. HEALY
Connaught Medical Research Laboratories, University of Toronto

THE culture of organs is a specialized form of tissue culture. By suitable methods it is possible to maintain embryonic organs *in vitro* in a differentiated state under conditions that permit the study of their growth and metabolic activities. We have recently employed chemically defined media, which were originally devised for chick and mouse cells, for the cultivation of the cartilaginous femora and tibiæ of 6–7 day chick embryos, and our main findings are summarized here in order to illustrate the type of result that can be obtained with these media. Fuller descriptions of special aspects of this work will be published later. The further development of this field of investigation is important for the quantitative study of the relation of specific substances, for example, hormones, vitamins and amino-acids, and their metabolism to processes of growth and differentiation.

Although previous work on chemically defined media has been largely concerned with unorganized growth, a few papers have recorded the results of using such nutrients in organ culture. Spratt[1] utilized a medium based on White's formula[2] for cultivating early chick blastoderms. Et. Wolff and his colleagues[3] described the growth of embryonic chick tibiæ, gonads and syringes on a fairly simple mixture of amino-acids, vitamins and inorganic salts made up in agar. More recently, Trowell[4] has designed a slightly more complex medium for the culture of mammalian lymph nodes.

Three basic media have been used: 770, 858 and 929; these were prepared in the University of Toronto, Toronto, Canada, and sent by air to the Strangeways Research Laboratory, Cambridge, where many of the experiments were done. Some of the later experiments have been performed in the Department of Physiology, Royal Veterinary College, London.

Medium 770 is identical with medium 703 except for the addition of 0·1 per cent chondroitin sulphate[5]; medium 929 differs from medium 858 in that the concentration of all amino-acids is doubled[6].

The femora and tibiæ from 6½–7 day old chick embryos were used in this work. It must be emphasized at the outset that the embryonic bones are cartilaginous rudiments with only a slight degree of periosteal ossification as a collar around the diaphysis. The bones were cultured by the floating lens paper technique devised by Chen[7] for use with liquid media. In all but the isotope experiments the volume of medium in each culture vessel was 0·5 ml.; in some experiments, at the end of a culture period, the medium was recovered quantitatively for biochemical analysis. Three responses of the bones have been measured: length (from camera lucida drawings), wet weight and total nitrogen. These responses, however, have not been measured concurrently in all experiments.

The femur and tibia from one limb were usually kept together in the same culture vessel and thus constituted the experimental units that were allotted at random to the treatments in the different experiments. Three types of experimental design have been used: completely randomized, split-plot and the balanced incomplete block. In the first design, considerable reduction of experimental error was achieved by eliminating the effects of variations in the initial length of the bones by an analysis of covariance. The second and third designs were used specifically for exploiting the uniformity of paired bones from the same embryo. All experiments have been analysed by standard analysis of variance procedures[8] following transformation of the observations to the logarithmic scale.

Growth of the Bones

The bones were cultivated for twelve days in medium 929 containing glucose 2·25 mgm./ml., the medium being renewed every fourth day. After ten days *in vitro*, the average length of the femora increased by 110 per cent, and that of the tibiæ by 120 per cent, over their initial length. A subsequent factorial experiment[9] demonstrated that for a given level of glucose in the medium greater elongation is obtained when the medium is changed more frequently. The bones remained fairly normal in shape (Fig. 1), although this was not always so, since the ends of the rudiment sometimes became attached to the lens paper and therefore the bone was forced to bend when it elongated.

The same degree of elongation is observed over a four-day period of cultivation on both media 858 and 929, but is less in medium 770. Since several components were changed in the development of medium 858 from 703, it is not possible to attribute the greater response obtained with medium 858 to any particular constituent.

Histological examination of bones that have been cultivated for periods up to six days shows the normal structure, but in those grown for six days or more, degenerative changes are usually present, particularly in the diaphysis. The degeneration is slight at six days (Figs. 2, 3 and 4), but thereafter it becomes widespread. A collar of periosteal bone is present around the diaphysis. Until further work is done, however, it is not possible to state whether ossification

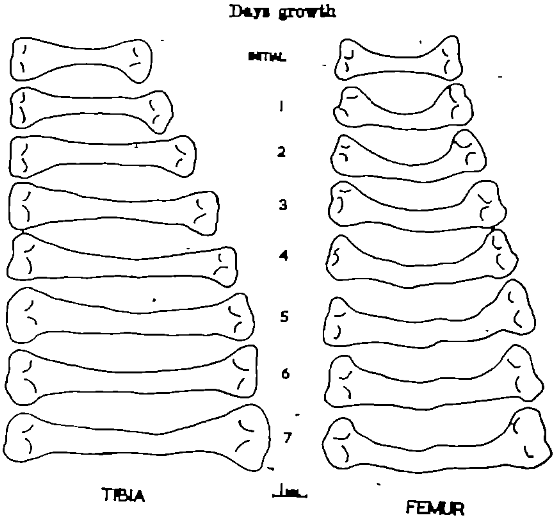

Fig. 1. Daily camera lucida drawings of an embryonic chick femur and tibia cultivated on medium 929 (glucose concentration 2·25 mgm./ml.). The medium was renewed on the fourth day

continues in bones cultivated on this medium. Other histochemical studies have shown that, after cultivation on the chemically defined medium, the matrix of the cartilage stains metachromatically with toluidine blue.

The rudiments differ in some respects from those kept for the same time on a natural medium containing serum, although they elongate to about the same extent on both nutrients. Very often the shafts of the bones grown on media 858 and 929 are flattened and slightly distorted, and the rudiments have a translucent appearance. Bones grown on media containing serum are more normal in shape, appear much denser and weigh significantly more than those grown on medium 929 ($0·05 > P > 0·01$).

Utilization of Amino-Acids from the Medium

A series of experiments have been made to investigate the disappearance of amino-acids from the medium during four days cultivation. The medium was quantitatively recovered and analysed for total amino-nitrogen by a ninhydrin method[10]. The ninhydrin colour given by the medium before use is due almost exclusively to amino-acids. Throughout the cultivation period, however, a quantity of ammonia may be formed, the presence of which would contribute to the intensity of the colour produced.

Table 1 shows the amino-nitrogen that is utilized during cultivation of the femur and tibia for one and four days on media 770 and 858. Although the extent of the interference due to production of ammonia is unknown in these experiments, the results clearly demonstrate that there is considerable loss of amino-nitrogen from the medium. The utilization of individual amino-acids from the medium can be conveniently followed by ion-exchange chromatography. Preliminary results, illustrating the application of the method of Moore and Stein[11] to the determination of the amino-acid metabolism of bone rudiments, have been described elsewhere[9]; this work has been considerably extended by Lawson and Lucy (unpublished observations).

Table 1. Amino-nitrogen (μgm.) utilized from 0·5 ml. Medium by a Femur and Tibia after 1 and 4 Days Cultivation (Means of 8 Observations)

Days cultivated	Medium	
	770	858
1	7·60	6·77
4	15·1	18·2

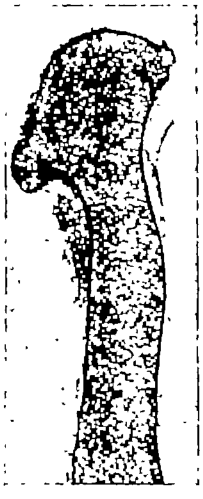

Fig. 2

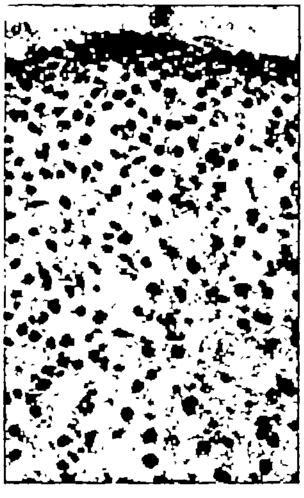

Fig. 3

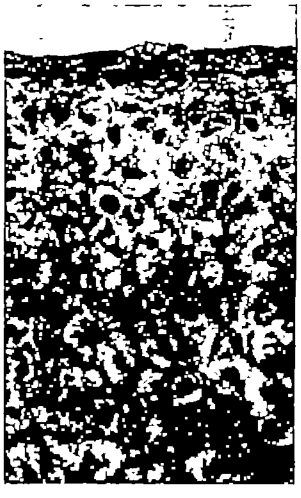

Fig. 4

Fig. 2. Seven-day old embryonic chick tibia after six days cultivation on medium 858. The medium was renewed on the third day (× 12). The structure of the bone appears normal with distinct epiphyseal cells and hypertrophic cells

Fig. 3. Part of the epiphysis of the specimen shown in Fig. 2, showing viable rounded cells (× 244)

Fig. 4. Part of the diaphysis of the specimen shown in Fig. 2, showing the periosteum and hypertrophic cells (× 244). The zone of ossification occurs between these two layers

Incorporation of amino-acids into the protein of the explants has been shown by the uptake of radioactivity by the bone rudiments cultivated for 24 or 96 hours in medium 929 supplemented with glycine-1-^{14}C (0·04 mgm. = 1·32 μc./5 ml. medium). In these experiments the bones were extracted to remove lipids and nucleic acids, and the protein residues hydrolysed for 18 hr. with 6 *N* hydrochloric acid at 110° C. After removal of the hydrochloric acid *in vacuo*, the liberated amino-acids were separated by two-dimensional chromatography on paper[12]. Autoradiography of the chromatograms showed high activity in the glycine spot. Activity was also present to a lesser extent in serine, indicating some synthesis of this amino-acid from glycine. It is probable that, in addition to glycine, certain other amino-acids, for example, aspartic acid and glutamic acid, are utilized both directly through incorporation into protein and indirectly through the synthesis of other cell components.

In other experiments, in which bones of a similar size were used, it was found that during four days cultivation the combined total nitrogen of a femur and tibia increases by only 1·38 μgm. Thus, only a fraction of the amino-nitrogen that disappears from the medium reappears in the bones. The deamination of amino-acids by the bone rudiments has not been investigated in detail, although evidence from other

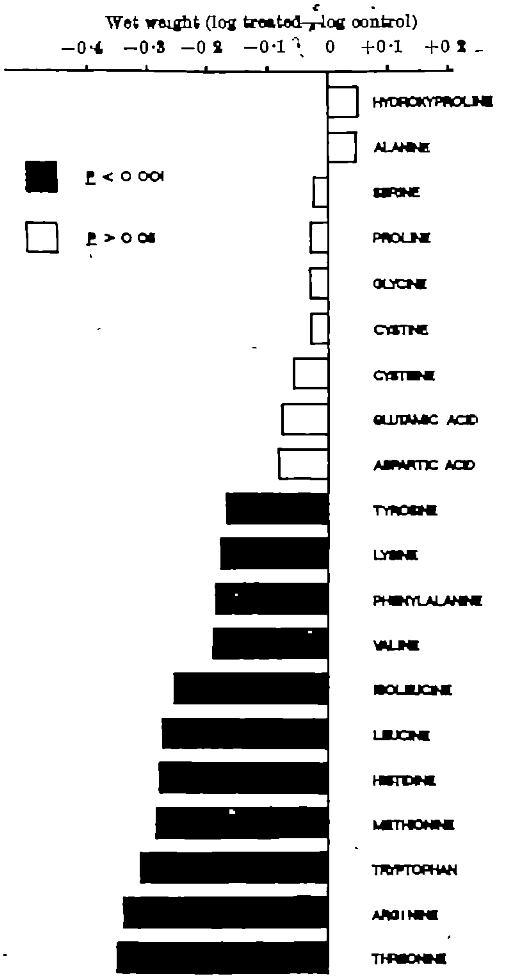

Fig. 5. Effect of individual amino-acid deficiencies on the wet weight of the bones after six days cultivation. The medium was renewed on the fourth day. Control medium: 858 (glucose concentration 2·25 mgm./ml.)

systems in which both ammonia and total amino-acids have been determined suggests that deamination accounts for much of the decrease in amino-nitrogen[9]. In the bone cultures, pyruvic acid, α-keto*iso*valeric acid and α-keto*iso*caproic acid, the deamination products of alanine, valine and leucine, respectively, have been isolated from medium 929 after a four-day culture period.

‘Essential’ Amino-Acids

The results described in the previous section demonstrate that amino-acids are utilized from the medium during the incubation period. This raises the question of whether or not certain amino-acids are ‘essential’ for growth under the conditions of the present experiments. It was considered worth while, as an initial step, to perform *in vitro* experiments on the bone rudiments analogous to the classical deficiency experiments of Rose on the whole animal. It must be remembered, however, that recent nutritional studies on whole animals have demonstrated that the determination of these ‘essential’ requirements is a very complex process[13], because of the way in which the level of one component of the diet may determine the requirements for another. These, and several other related problems, have been discussed recently with reference to the design of chemically defined media by Biggers, Rinaldini and Webb[9].

Twenty media were prepared, each deficient in one amino-acid, and the response obtained with each of these media was compared with that on a control medium containing all the amino-acids. A double-strength stock medium (858) containing no amino-acids was prepared in Toronto. Just before use, this medium was diluted with the appropriate amino-acid solution. The amino-acids used were all of the L-form and had satisfied critical tolerance tests for purity.

The results obtained with the tibia are summarized in Fig. 5. The response has been estimated in terms of wet weight, a measure that has been found in other experiments to be highly correlated with total nitrogen. Since the work could only be done in several experiments, a control treatment was included in each, and the response expressed as $D = T - C$, where in a particular experiment T is the mean logarithm of the wet weight of bones subjected to a specific deficiency and C is the mean logarithm of the wet weight of the control bones. The effect of any one deficiency has been studied in two independent experiments of different design. Thus, two estimates of D were available, and these were found to be consistent with one another, within the limits of experimental error. The results shown in Fig. 5, therefore, are the weighted means (D_w) of these two estimates, the weight attached to each being the reciprocal of the corresponding variance[14].

If the amino-acid is ‘non-essential’, the value of D_w is expected to be zero. We may calculate the variance of D_w and use a t test to compare D_w with zero. If the probability of the test is less than 0·05, the amino-acid is said to be essential; otherwise it is non-essential.

Fig. 5 shows that nine of the amino-acids are non-essential under the conditions of the experiments, although glutamic acid and aspartic acid are on the border-line. The remaining eleven are all essential to a very high level of significance, and thus the amino-acids fall into two clearly defined groups.

Deficiencies of some amino-acids, for example, threonine, arginine (Fig. 6) and tryptophan, produce

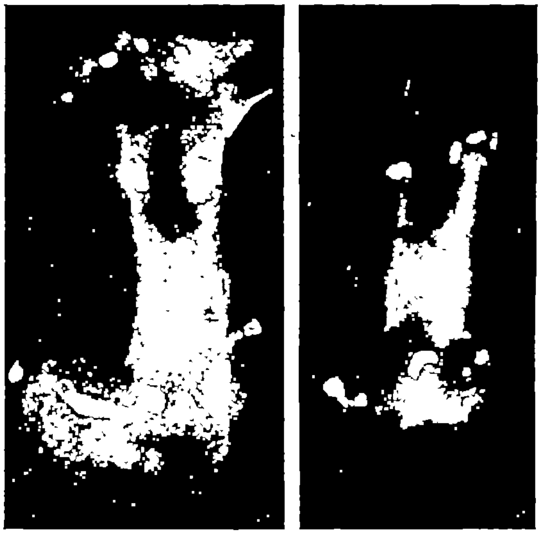

Fig. 6. Living tibiae after six days cultivation: (*a*) control medium; (*b*) an arginine-deficient medium. Both were from the same embryo and initially of approximately equal size. (× 15)

a great depression of growth. In these the deficiency appears very early and can be discerned within 48 hr. of setting up the cultures. The effects of other amino-acids are manifested more slowly; for example, lysine deficiency. Possibly this is due to the presence of stores of the amino-acid in the bone and a slow rate of utilization.

The amino-acid requirements of 7-day old embryonic chick tibiæ have also been studied by Kieny, Haffen and Wolff[15]. These workers have found that only certain amino-acids are required, but there is not full agreement with our results. Since the conditions of their experiments, both in regard to the nature of the medium and the culture technique employed, differ considerably from ours, it is not possible to explain these differences until more work has been carried out. The investigation of these discrepancies should provide valuable information on the function of amino-acids in the development of embryonic cartilage.

Synthesis of Amino-Acids from Glucose

The fact that the omission of certain amino-acids from the medium has no effect on the growth of the rudiment raises the question of the ability of the tissue to synthesize these compounds from other constituents of the medium.

Since a likely source of amino-acids is glucose, we have carried out experiments in which generally glucose labelled with carbon-14 was added to medium 858. After 24 hr. incubation on this supplemented medium, the bones were fractionated and the protein residue hydrolysed with hydrochloric acid. The amino-acids were separated by two-dimensional chromatography and the radioactive spots located by autoradiography. Areas of the paper bearing these active components were cut out and the individual amino-acids eluted with water. Samples of these eluates were assayed both for radioactivity and amino-acid content, and from these results the specific activities shown in Table 2 were obtained.

It can be seen that radioactivity is present in alanine, aspartic acid, glutamic acid, serine, glycine and proline, indicating that glucose can act as a source of all these 'non-essential' amino-acids.

Conclusion

The results summarized in this paper demonstrate that growth processes can be studied in embryonic bones cultivated on chemically defined media.

Table 2. SPECIFIC ACTIVITIES OF THE AMINO-ACIDS ISOLATED FROM THE PROTEINS OF THE BONES CULTIVATED ON MEDIUM 858 CONTAINING GLUCOSE-^{14}C

Amino-acid	Specific activity (counts/min./µmole) Tibiæ	Femora
Alanine	12,000	13,500
Aspartic acid	—	8,900
Glutamic acid	7,700	6,800
Serine	1,930	2,300
Glycine	930	680
Proline	840	—

Although the experiments made thus far have been purely exploratory, it is clear that the results open several fields of investigation, concerned not only with the metabolism, differentiation and growth of cartilage, but also with the general problem of improving these media for more general use and for use in other specific undertakings. The fact that responses can be obtained, however poor they may be as compared to those in natural media, should encourage further work in this aspect of organ culture.

We thank Dr. H. B. Fell for helpful advice in the preparation of this manuscript. One of us (J. D. B.) is indebted to Dr. Fell for the facilities provided at the Strangeways Research Laboratory for investigating the use of chemically defined media in organ culture, and the Royal Society and the Central Research Fund of the University of London, for generous grants in support of the later phases of this work. The Canadian part of the study was supported in part by grants from the National Cancer Institute of Canada.

THE KIRUNA GEOPHYSICAL OBSERVATORY, SWEDEN

By Dr. BENGT HULTQVIST
Director

AT a ceremony on July 2 marking the formal opening of the new Kiruna Geophysical Observatory in northern Sweden, the Royal Swedish Academy of Science accepted from the contractors the new central observatory building and the ionospheric laboratory. Representing a decade of planning and work, this fine new facility in northern Sweden will enable geophysicists interested in arctic phenomena to carry on research under the most favourable conditions.

The dedication ceremonies were attended by more than a hundred guests, including the Governor of Norrbottens län and Mrs. M. Näslund; State Secretary Dr. Ragnar Edenman, representative of the Swedish Government; Prof. Bertil Lindblad, vice-president of the Royal Swedish Academy of Science; Dr. Hugo Larsson, director of the National Defence Research Group in Sweden; Mr. H. Nyström, head of the Kiruna City Council and State representative; various members of the Board which had

been set up to deal with the funding and planning of the new Observatory, including Prof. Rolf Sievert, Dr. Nils Ambolt and Prof. Harald Norinder; Dr. L. V. Berkner and Dr. J. W. Joyce from the United States; Prof. J. Keränen and Prof. H. Fransila from Finland and Prof. Harang from Norway.

The Observatory consists of a main building and a series of smaller buildings for housing various types of instruments (see plan, Fig. 1, and Figs. 2–4). It occupies an area of 22·2 sq. km., which provides amply for future expansion, including the establishment of auxiliary observing sites where measurements over base lines of several kilometres are desirable. The geographical location is particularly significant with respect to the Geophysical Institute in Fairbanks, Alaska, because the two observatories are approximately 180° apart in longitude. This circumstance will make it possible for the two laboratories to undertake certain important types of trans-polar research projects on a co-operative basis. Co-ordinates of the new Kiruna Geophysical Observatory are as follows: geographic co-ordinates, lat. 67·8° N., long. 20·4° E.; geomagnetic co-ordinates, lat. 65·3° N., long. 115·5° E. Corresponding co-ordinates for the Geophysical Institute at Fairbanks, Alaska, are: geographic, lat. 64·9° N., long. 147·8° W.; geomagnetic, lat. 64·5° N., long. 255·4° E.

The main building contains a series of laboratories, dark-rooms, administrative offices, combination library and seminar room, dining-room and lounge facilities, living quarters for investigators, a well-equipped mechanical workshop, and other features. One large laboratory room can be subdivided into three small rooms if necessary, each suitable for one or possibly two workers. A second laboratory provides facilities for several people, and five smaller rooms are equipped to accommodate one or possibly two people. General laboratory services are available in each of the rooms and special features have been added to certain of these.

On the upper floor of the main building is a heated glassed-in laboratory. Above this is an open deck on which can be mounted equipment requiring all-round seeing conditions. The mounting facilities are provided with supports that go down to foundations and are independent of the structure of the building itself.

The main building includes living quarters for the director and for a general caretaker and six individual sleeping rooms for visiting investigators. Two small cottages, at present under construction, will provide living space for permanent staff members.

A grant from the U.S. National Science Foundation has made it possible to equip the Observatory with good basic instrumentation.

Both normal and quick-run geomagnetic records of X, Y and Z have been taken regularly for several years. The aurora is studied with a Stoffregen all-sky camera. A panoramic ionosonde was set up in a

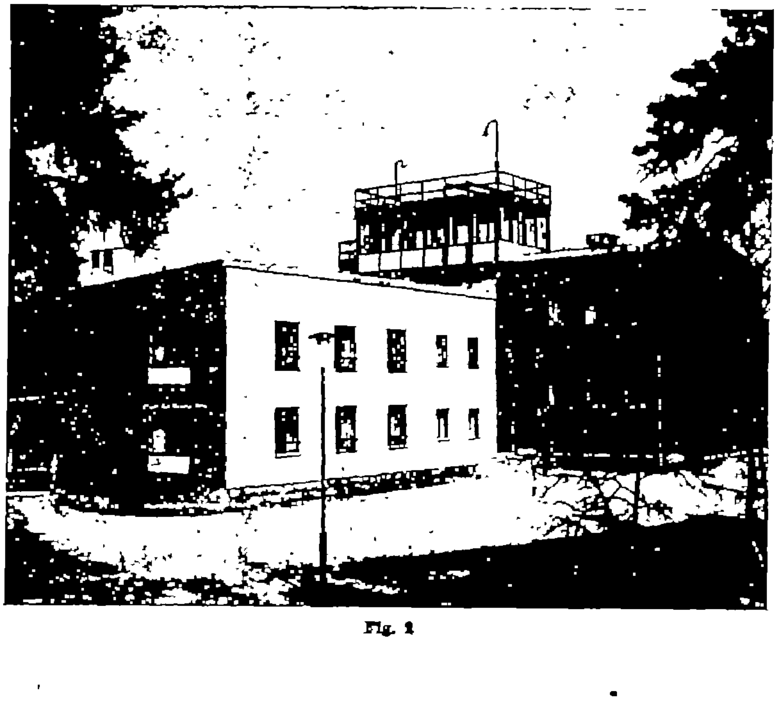

Fig. 2

Fig. 3

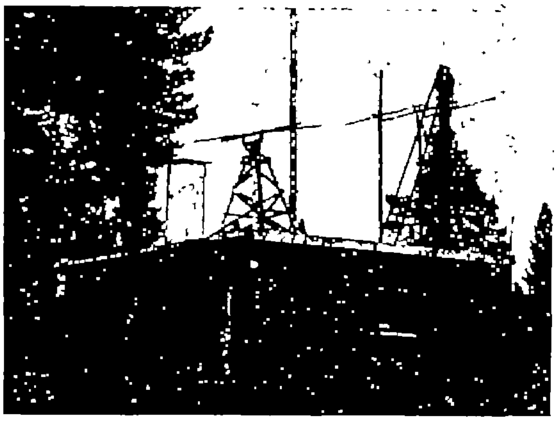

Fig. 4

provisory building in 1948. Two registration houses are now accommodating two special-purpose cosmic-ray telescopes besides two 'international cubics'. A widely separated set of counters for investigation of extensive air showers is under construction. In 1951 four seismographs were installed in a special building at the Observatory.

The establishment of a first-class geophysical observatory near Kiruna was proposed by the Royal Swedish Academy of Science more than a decade ago. Its planning has been in the hands of a special Board appointed by the Royal Swedish Academy of Science. The members of this Board are: Senator Dr. R. Sandler (chairman); Dr. R. Sievert (vice-chairman), professor of radiophysics, Royal Caroline Medical-surgical Institute, Stockholm; Dr. H. Alfvén, professor of electronics, Royal Technical University of Stockholm; Dr. N. Ambolt, director of the Section of Terrestrial Magnetism, Royal Board of Shipping and Navigation, Stockholm; Dr. R. Florin, professor of botany, University of Stockholm; Dr. B. Hanström, professor of zoology, University of Lund; Dr. E. Hulthén, professor of physics, University of Stockholm; Dr. H. Köhler, professor (emeritus) of meteorology, University of Upsala; Dr. B. Lindblad, professor of astronomy, University of Stockholm, president of the Swedish Natural Science Research Council; Dr. H. Norinder, emeritus professor of electrophysics with special application to atmospheric discharges, University of Upsala; Dr. A. Nyberg, director-in-chief, Swedish Meteorological and Hydrological Institute, Stockholm.

We welcome suitable research proposals, particularly where appropriate financial support can also be provided. All proposals by those interested for co-operative activities should be addressed to the Director, Kiruna Geophysical Observatory, Kiruna, Sweden.

THE BIOLOGY OF CANCER

THERE has been an increasing awareness in recent years among those engaged in research of a need for a more fundamental biological approach to the problem of cancer. The general study of viruses was, at one time, looked upon as a pathological problem; but it is now recognized as of importance both in its general biological aspects and in the elucidation of the microstructure of cellular systems. It was therefore refreshing to find this view reflected in a whole-day discussion on "Biological Aspects of Cancer" held by Section D (Zoology) of the British Association in Dublin on September 6. Prof. Rogers Brambell, the chairman for the morning session, regretted the tendency to separate the study of cancer from the general framework of zoology, and emphasized the close relationship between protein synthesis and pathological changes within the cell. Prof. A. Haddow (Chester Beatty Research Institute), who opened the discussion, stressed the fundamental similarity between embryonic and cancer cells, and the need for more information concerning the development of specific enzymes during embryonic development and differentiation.

It was unfortunate that Dr. Julian Huxley was prevented by illness from reading his paper. In some excellent recent reviews, he has stressed the importance of considering the zoological aspects of the problem. He looks upon tumours as constituting a separate major phylum of obligatory parasites, originating and usually perishing with the host, with a way of life most fruitfully considered in the general biological concepts of adaptation, evolution, population dynamics and the like.

Here it will be convenient to consider three aspects of the problem discussed at the meeting, namely, growth mechanisms and their regulation, population dynamics of tumours and the nature of the intracellular transformation giving rise to the manifold properties of cancer cells.

The nature of the environmental controls, by which a healthy organism prevails upon its many cells to adopt and maintain a sociable way of life and which the cancer cells have to overcome, was tackled by several speakers. A knowledge of how these controls are effected remains a major problem of current biology, but there is little doubt that chemical substances, humoral factors, pass from organ to organ influencing both the function and size of the organs. Prof. E. S. Horning (Chester Beatty Research Institute) described the two types of cancer which arise spontaneously in both animals and man. One type comprises a group of malignant tumours the growth of which can be controlled temporarily by an alteration of the hormonal environment of the body in which they develop. Cancers which respond to this kind of therapy are called hormone-dependent tumours. They are often, but not always, caused by a hormonal imbalance, and are dependent upon a particular hormone or combination of hormones for their sustained growth. Many of these tumours in both animals and man regress once the hormonal stimulus is withdrawn. Prof. Horning went on to describe tumours in the hamster induced by prolonged treatment with the synthetic female sex hormone stilboestrol. These are an interesting example of a hormone-dependent lesion as they grow, when transplanted under the skin of hamsters, only if they have been pre-treated with oestrogen. These particular tumours have been growing as serial transplants for more than four years, and still remain dependent for their growth on hormones.

An example was also given of the induction of a prostate hormone-dependent tumour in the mouse without employing the direct intervention of a hormonal agent. This prostatic cancer was produced by treatment with one of the carcinogenic hydrocarbons, namely, 20-methylcholanthrene. Many of these primary prostatic tumours were glandular cell carcinomas, and were found to be dependent upon androgens for their maintenance as transplants. During serial transplantations, all these tumours eventually underwent squamous differentiation, and they then became independent of the male sex hormone for their sustained growth as grafts. The dividing line between the hormone-dependent tumours and those which are completely autonomous is not completely rigid. A certain number of dependent tumours, like the mouse prostate carcinoma, transform into autonomous variants, indicating some progressive type of cellular transformation.

In addition to cellular proliferation, tumours may be characterized by their degree of de-differentiation. Differentiation is the process whereby the potentialities of the cells become restricted from the totipotential state of the fertilized egg to the decreased potential state of a muscle cell, red blood cell or cornified cell. Dr. A. Glucksmann (Strangeways Research Laboratory, Cambridge) pointed out that in normal growths, as in epithelium, there is a balance between rate of growth and rate of differentiation. In the development of cancers, this balance may be altered in rate, quality, uniformity of progress and in the type of differentiation impaired. Such changes can arise independently of each other. As in the case of proliferation of cells, changes in differentiation can be brought about by extrinsic environmental conditions, such as hormonal factors operating on the normal or slightly impaired potentialities of the cancer cell.

Another type of change in the cell itself is an alteration of its surface properties. Evidence is accumulating that cell movement, for example, and possibly cell division, are influenced by contact with other cells. Dr. Abercrombie discussed the mechanism of cell movement, which is a property, like that of division, latent in most cells, but which becomes manifest again only when the environmental conditions alter, as in wounds or when cells are transferred to a culture medium *in vitro*. This work has been considerably assisted by the technique of interference-microscope cinematography, which reveals the dynamics of cell movements very clearly. The movements of fibroblasts and perhaps of other cells are associated with peripheral undulations of the cell membrane. When this undulating surface touches another fibroblast, the activity ceases at the point of contact and an adhesion may be formed. These adhesions occur in the phenomenon of inhibition by contact described by Abercrombie and Heaysman. If the cell is in contact with a sufficient number of surfaces its entire membrane becomes quiescent and movement ceases, as is the case in an established tissue. The discovery that cancer cells are not subject to contact inhibition may be of far-reaching importance. In mixed cultures cancer cells may be seen to move freely over the surfaces of normal cells, which are themselves held motionless, owing to the effects of contact inhibition. It would seem that we have here one of the secrets of the 'success' of the cancer cell. That contact inhibition is a potent factor in tissue construction would seem obvious; in gaining independence from its operation the cancer cell has clearly made the important step towards autonomy and its ability to invade normal tissues can also be understood on this basis.

The films indicate that sarcoma cells in culture do not form permanent adhesions between their undulating membranes. This suggests an alteration in the surface properties of cancer cells, a point of view which has long been held by Coman, who has demonstrated by direct manipulation that cancer cells are less sticky than normal cells. Cancer cells have also recently been found by Ambrose and his co-workers to carry a higher negative electrical charge than homologous normal cells. Clearly these properties are linked, but until more is known of what happens when one cell touches another and what makes some cells stick together and others not, the relationship between cell adhesion, contact inhibition and tissue construction can only be guessed.

The fine details of the structure of the cell membrane and of the contacts themselves are now within the province of the electron microscopist. Owing to the recent technical advances allowing the cutting of sections thin enough for electron microscopy, there has been a rapid growth in our knowledge of the fine structure of cells. Dr. E. H. Mercer (Chester Beatty Research Institute) described how these techniques are being adapted to the problem of cell contact and cell adhesion. By the choice of certain simple cell systems, such as the mammalian epidermis and a species of social amœba, in which the cells progress from a relatively free-living condition to form well-differentiated structures, the behaviour of the cell membranes can be followed. The external membrane of the amœbæ at high resolution is resolved into a lamellar structure about 60 A. thick, consisting of two dense surfaces enclosing a less dense layer. In some instances, the membranes of other cells can also be resolved in this way. The structure may correspond to the model of two protein layers spread over a lipoid-like layer proposed by Danielli. When two cells meet, the plasma membranes flatten out, implying that the cells 'wet' each other, but the dense layers of the membranes never actually meet. They remain separated by a thin layer of less-dense material, 150–200 A. thick. This suggests the presence of some extracellular cementing substance outside the plasma membrane.

Such a material should obviously play a key part in tissue formation and maintenance and will affect many of the surface properties of cells. The possibility of a loss in quantity or perhaps quality of this cement is suggested by electron micrographs of anaplastic tumours the membranes of which show poor attachment. In more differentiated tumours, however, the morphology of the contacts still appears normal.

The nature of the cell surface was further discussed by Dr. R. J. Goldacre and Drs. G. C. and D. M. Easty. Dr. Goldacre (Chester Beatty Research Institute) pointed out that many of the fundamental aspects of cell physiology can be studied with any type of living cell. The large *Amoeba proteus* is a convenient test organism in which cellular changes can be seen much more easily by eye than in the smaller tissue cells. Certain carcinogens such as nitrogen mustards and diepoxides can be seen to have a direct tanning effect on the membrane, preventing the animal from retracting its pseudopods. He showed a film which indicated that at least a part of protein synthesis takes place at the cell membrane. Since there is considerable experimental evidence that the cell membrane is altered in cancer cells, this could account for an altered type of protein synthesis. Another possibility is that membranes are concerned in the transfer of information from one cell to another, and that this transfer could be impaired were the membranes modified.

Dr. and Mrs. G. C. Easty (Chester Beatty Research Institute) were concerned to show, by means of specific surface antisera, that the surfaces of the cells of different organs were different antigenically and that, in a particular transplanted tumour they examined, the tumour cells differed from normal cells. An antiserum to a cell can produce three effects: precipitation of cells, aggregation and a change in permeability of the membrane. This last effect can be particularly well seen in the interference microscope because it is associated with a sudden passage of cytoplasmic protein from the cell, which can be observed as a dramatic change of colour in the interference image. An antiserum against ascites cells contains antibodies against a variety of cells, but is purified by adsorbing against normal cells and can be obtained with an increased degree of specificity against the cancer cells. Films show that this antiserum reacts specifically with the membrane of cancer cells in the presence of other normal cells. This result raises the possibility of a tumour-specific antiserum in therapeutics, but requires further investigation using primary tumours. Dr. Easty also showed that in some tumours the antiserum reacts on some cells without affecting others, indicating the presence of a heterogeneous population.

In general biological terms we may now ask ourselves what is the origin of the new species of cells? Probably the new cells are mutants less under the control of those environmental factors which are able to repress the spontaneous tendency of the unmutated stock to divide. Mutants, capable of complete autonomy, probably do not arise in a single step. The initial variants may be supposed to have a slightly enhanced autonomy, but can probably only increase in a localized host environment where the normal powers of control are impaired by the action of some promoting condition. In such conditions, natural selection operating on a mixed population of altered cells may be relied upon to select a strain of increasing autonomy. Prof. P. C. Koller (Chester Beatty Research Institute) showed a selection of cell smears illustrating chromosomal variations. These provide visual proof of the fact of chromosomal change in cancer cells and also of the existence of numerous chromosomal variants in the cell population, implying the presence of mutant forms. This can clearly be seen in the diversity of chromosome number. These changes are brought about largely by abnormal mitosis, such as lack of synchronization of nuclear and cytoplasmic division. Multiple spindles, operating on a mass of chromosomes, and the occurrence of anaphase bridges also lead to variations in the nuclear size of daughter cells. Cellular polymorphism provides a basis for the operation of selection as the tumour develops, invades and occupies new situations. This may be shown by changes in the number of chromosomes between the primary and secondary tumours. Certain cell variants may also be favoured during therapeutic treatment when the cells are subject to radiation or chemotherapeutic agents. Prof. G. Klein of Sweden has also studied this problem using transplantation techniques, and has produced a number of strains from a single tumour which show differences in degrees of invasiveness and other biological behaviour.

The origin of the new types of cell, in chemical carcinogenesis, was discussed by Prof. Haddow. He pointed out that chemical carcinogenesis provides a direct experimental approach to this problem. Since the discovery of the carcinogenic hydrocarbons a number of comparatively simple chemical substances have been discovered which can induce cancer, for example, the nitrogen mustards, epoxides, and ethyleneimines. Their possible reactions with biological material are limited; the nitrogen mustards, for example, operate by alkylation. Those which are of a bifunctional nature are far more active biologically than monofunctional compounds. Another advantage of these compounds, from the point of view of experimental observation, is that they have a rapid effect upon the cell. A number of direct cytological changes are produced by these agents: fragmentation of chromosomes, anaphase bridges, interference with chromosome duplication, and formation of micronuclei. Such effects are also produced by radiation, and the substances are therefore called radiomimetic agents. The direct effect of these agents upon nucleic acid *in vitro* is known, and it appears distinctly possible that their biological reaction is with this component of the cell. They are found to have a marked mutagenic action in *Drosophila*. Although some alteration in the genetic constitution of the cell may be involved in the malignant change, control of growth in terms of cellular dynamics probably depends upon enzyme systems. Xanthopterin, for example, will produce a wave of mitosis in kidney tubules. Xanthine oxidase appears to be the enzyme which controls the level of xanthopterin in normal tissues, and there is some evidence that its concentration is reduced in some tumours.

There were some rather obvious omissions from the programme in Dublin. Little was said about the virus theory of cancer, although a number of mammalian tumours have recently been shown to be of viral origin. Nor was the immunological response of the host to a growing tumour examined. But it was obviously impossible to cover all these aspects in a single day.

PROTEIN STRUCTURE AND BIOLOGICAL ACTIVITY

PARIS SYMPOSIUM

IN 1951, a Commission on Proteins was created within the Section on Biological Chemistry of the International Union of Pure and Applied Chemistry. Its aim was to consider the possible need for, and provision of, a few standard proteins, rigorously tested by both chemical and physical methods, and available internationally to anyone who might wish to check his own methods against a standard. The first protein to be distributed in this way was a large batch of crystalline beef insulin*, prepared in Great Britain by the British Insulin Manufacturers.

The description 'standard' is used advisedly, for one is hesitant to apply any longer within the field of protein chemistry a term with the finality of 'homogeneous'. In recent years, the most respectable proteins have been resolved by several kinds of simple and sensitive techniques into two or more components, each perhaps with the same biological activity, but differing slightly in some chemical or physical feature. In some cases, it is not known how such 'microheterogeneity' arises; but just as Kossel in 1901 squarely faced the great diversity and complexity of proteins as a class—attributes which had taken fifty years to establish—so now the biochemist must anticipate the diversities which may arise in any one protein, either genetically as a mutation, as the result of species differences, as slight modifications in the course of preparation, or perhaps, as Pauling suggested, as an occasional mistake in the biosynthetic mechanism.

The Commission decided at its meeting in Zurich in 1955 that a symposium on protein structure and its relation to biological activity would greatly assist the Commission in evaluating the relevance of its earlier objectives. The executive committee of the International Union of Pure and Applied Chemistry, through Dr. Murray Luck, gave generous financial help, which enabled the organizers, Dr. Stanford Moore (United States), Prof. A. Neuberger (Great Britain) and Prof. J. Roche (France), to invite some twenty distinguished speakers and as many others to a symposium held in Paris during July 25–29, following the nineteenth Conference of the International Union of Pure and Applied Chemistry itself. Both papers and discussions will eventually appear as a monograph†, and the present account (prepared in the main without reference to manuscripts) cannot possibly do justice to the uniformly high standard of the communications, reflected by the enthusiasm of the audience in the congenial atmosphere of the Collège de France.

Following the usage of Linderstrøm-Lang, it is convenient to consider the structural concepts of proteins in terms of the primary structure (amino-acid sequence), secondary structure (*intra*-molecular configuration of the polypeptide backbone —CH.CO.NH—) and the tertiary structure (*inter*-molecular bonding and topography of the side-chains). Although our knowledge of secondary and tertiary structure is only fragmentary, it became evident during the meeting that a bold and imaginative approach by several workers had yielded fascinating results. It was also quite evident that the revolutionary progress in defining primary structure arises first from the application of many kinds of chromatographic techniques, and second from the introduction and expansion of end-group methods. It is not yet possible to assess in any historical sense the debt we thus owe to the pioneers in these fields, Martin and Synge on one hand, and Sanger on the other.

Primary structure. The complete elucidation of the amino-acid sequence in insulin has led to more ambitious attempts to determine that of much longer chains. Through the work of S. Moore and W. H. Stein, and of C. B. Anfinsen and their co-workers, one may anticipate very soon the complete sequence in ribonuclease, a chain of 124 residues, in which the positions of the intrachain disulphide bridges have already been allocated. Steady progress was also reported by Cl. Fromageot and his colleagues in the case of hen lysozyme (128 residues), a difficult protein by virtue of its high content of tryptophan. The structure of pig and ox adrenocorticotropic hormone, described by C. H. Li (39 residues), has a fascinating interest in view of the occurrence of amino-acid sequences common also to the α- and β-melanophore-stimulating hormones, the structures of which have been determined by C. H. Li and by J. I. Harris and their collaborators. Features which augment one type of biological activity at the expense of another are already apparent. The free amino-group in the terminal serine of corticotropin, which is correspondingly substituted by an unknown group in α-melanophore-stimulating hormone and by an additional peptide sequence in β-melanophore-stimulating hormone, appears to be necessary for its activity; if obliterated by oxidation, its corticotrophic activity is lost, although the slight melanophore-stimulating hormone activity persists.

In spite of the extension of sequence studies to these and other proteins and peptides, it is worth noting that the insulins are still the only proteins containing more than *one* polypeptide chain the complete structure of which is fully known.

Secondary and tertiary structure. The classical denaturing agents such as heat, acid, alkali and urea may induce reversible or irreversible changes of configuration which can now be followed by a variety of methods. K. Linderstrøm-Lang described the use of deuterium to study the exchangeability of the imide hydrogen atoms of the polypeptide backbone, and discussed the results obtained with poly-DL-alanine which is known to exist in the α-helical form of Pauling and Corey. The rate of exchange as a function of hydrogen-ion and hydroxyl concentrations has suggested that H-bonds can be broken singly only at the ends of the helix, whereas in other positions at least three must dissociate simultaneously. In both insulin and ribonuclease, the observations suggest that exchangeability is greatly restricted in some parts of the molecule, but is instantaneous in presence of denaturing agents, or after opening out the molecule by oxidation of the restraining intra- and inter-molecular disulphide bridges.

---

* *Nature*, 179, 567 (1957).

† To be published by Methuen and Co. (Great Britain) and by John Wiley and Sons (U.S.A.).

Changes in optical rotation, shifts in ultra-violet absorption, dilatometry and measurement of intrinsic viscosity may also reflect the extent of configurational change, and even where this is considerable, as in ribonuclease, biological activity can be retained. Indeed, the examples of this kind of phenomenon are now quite large, and have led two participants at the conference, Emil Smith and C. B. Anfinsen, to inquire how much of the protein molecule is simply 'junk'. Even covalent linkages may be extensively split as in the case of papain, discussed by Smith, where 50 out of 180 residues can be broken off by aminopeptidase without any loss in activity against five different substrates. B. G. Malmström's enolase —an enzyme occurring in several electrophoretically distinct forms—is also unaffected after the action of carboxypeptidase or of aminopeptidase, the latter splitting some eighty amino-acids from a particle of molecular weight 68,000. It is not very difficult in reality to envisage that an active centre can survive such changes, although we know too little about tertiary structure to predict whether it will or will not. Conversely, some slight change occurring near or within the active centre may abolish activity completely. In papain, only one —SH group out of six is chemically reactive, and this, if substituted, destroys activity. In ribonuclease, a covalent split four amino-acids from the C-terminal end inactivates, as does any modification of tertiary structure which results in the liberation of H-bonded phenolic groups.

The 'junk' hypothesis, while no doubt valid with respect to some kinds of biological activity, need have no general validity. Antibody formation, for example, is evoked by more than one configurational site of the antigen molecule. R. R. Porter described the isolation of a homogeneous fragment from an enzyme digest of serum albumin, less than one-fifth the size of the native protein. This, when studied immunologically, contains some of the sites involved in the binding of antibody (serum albumin itself being used as antigen), but others have been shed, and the behaviour of the fragment is still dependent upon the intactness of its tertiary structure. J. Reynaud has likewise shown that trypsin-digested tetanus toxin contains at least four products antigenically distinguishable in their combination with antibody.

In the broadest sense, the factors affecting the stability of a protein cannot readily be generalized. C. Tanford pointed out that effects due to charge are not symmetrical about the isoelectric point, and that H-bonding involving the ionic groups must also play a part. He inclines to the view that the 'unmasking' of titratable groups, first observed by the writer in the titration of edestin and studied in detail by Steinhardt in the case of hæmoglobin, is due primarily to a change in the apparent pK of ionizable groups, induced by a change of charge density due to unfolding. The expansion of a protein in this way may be an entirely reversible process, and the molecule, if treated sympathetically, may regain its configuration and solubility at the isoelectric point. The rate of return, however, is often slow, and may compete with the tendency of the expanded molecule to become aggregated and precipitated, that is, 'denatured'.

Ultimately, one hopes that the biochemist's approach to structure will be complementary to that of the X-ray crystallographer. J. C. Kendrew and M. F. Perutz discussed the value of the isomorphous replacement method, in which heavy-metal compounds or metal atoms have been introduced into myoglobin and hæmoglobin at a few selective sites. The two-dimensional Fourier projections at 6 A. resolution are virtually uninterpretable, but the three-dimensional projection at 6 A. of myoglobin begins to show rivulets of electron-dense material consistent with the gross morphology of polypeptide chains. Mrs. D. C. Hodgkin remarked that even a resolution of about 2 A. would be insufficient to resolve individual atoms, though it would suffice to disclose the general topography of some of the side-chains.

Chemical variation and biological activity. By studying the variations in primary structure of a given type of protein, either within a species or between species, important information can be gathered about the essential or dispensable parts of the polypeptide chain. H. Tuppy described how, in the case of cytochromes (where no microheterogeneity occurs), the peptide sequence of seven amino-acids around the half-cystine residues, which are linked covalently to the porphyrin group, is the same in ox, pig, horse and salmon. In the chick, serine replaces alanine, and in the silkworm, arginine replaces lysine; but in all, the span of two amino-acids between the cysteine residues allows a model to be built on the plan of an α-helix, in which the imidazole residue is able to bond with the metal of the protohæm.

Many abnormal hæmoglobins have hitherto been characterized in relation to a specific disease and by physical methods. Those responsible for sickle cell- and Hb-*C*-anæmia arise by a mutation in the locus for normal adult hæmoglobin. V. M. Ingram has compared the three forms of chromatography ('fingerprinting') of the tryptic digests, and finds a difference in only one peptide fragment. The sequence —glu.glu.lys— in adult is replaced by —val.glu.lys— in sickle cell anæmia and by —lys. glu.lys— in hæmoglobin-*C* anæmia. That such a slight change can so profoundly modify the physical properties of hæmoglobin is a problem far beyond our understanding at present.

The unique phosphorylation of serine in or near the active centres of certain enzymes by diisopropyl phosphofluoridate allows a comparison of sequence at a specific site in very different proteins. J. A. Cohen described how the sequence —gly.asp.ser.gly. gly— of chymotrypsin is replaced by —gly.glu.ser. ala.gly— in liver aliesterase. The substitution of similar side-chains, that of glu for asp and ala for gly, might imply that these are essential to the configuration of the active centre.

Activation of zymogens. The proteolytic enzymes are often secreted as inactive precursors which are converted to a functional form by a limited proteolysis. The schools of H. Neurath and of P. Desnuelle have greatly clarified the detailed events of these activations; but whether the active centre is created in the process, or simply revealed by unmasking, is still a matter for speculation. In trypsinogen, the liberation of one acidic hexapeptide from the N-terminal end produces the active enzyme. Desnuelle reported that the active split of this bond is accelerated by calcium ions, which at the same time suppress a more extensive proteolysis. Chymotrypsinogen can give rise to several chymotrypsins: a tryptic split at 1 in the sequence —leu.^{2}ser.arg.^{1} ileu.val— gives an active form (π), and a second split at 2 by chymotrypsin itself gives the δ-form. Further splitting by chymotrypsin at 3 and 4 in the sequence —tyr.^{4}thre.asp.^{3}ala— produces the class-

NH$_2$

ical α-form of Kunitz. Desnuelle has shown that it is possible to start in reverse and in complete absence of trypsin to cleave by the action of chymotrypsin the links at 2, 3 and 4 above to give modifications ('neochymotrypsinogens') which are still enzymically inactive.

Other activations involve quite extensive proteolysis. Recent work of Neurath's group shows that Anson's crystalline carboxypeptidase is in reality only one-third the molecular weight of the zymogen, the rest being lost as dialysable fragments. Miss G. E. Perlmann reported that, by the action of urea, pepsin itself can lose dialysable components, leaving a portion with increased specific activity. This finding again is relevant to the 'junk' hypothesis.

Virus structure. Advances with respect to the structure of tobacco mosaic virus were discussed by H. Fraenkel-Conrat, G. Schramm and Miss R. E. Franklin. An unexpected discovery of recent years is that the ribonucleic acid alone, in absence of protein, is infective; another, that the sub-units of molecular weight 18,000 can be reconstituted to form the giant virus particle either in the absence of, or in the presence of, the nucleic acid component. This finding should greatly assist the elucidation of the topographical relation of nucleic acid and protein. Fraenkel-Conrat reported a feature of more general importance in protein chemistry—that the N-terminal residue (serine) of the sub-unit is substituted by an acetyl group. The indirect evidence for cyclic chains in proteins, resting as it does on the apparent absence of C- and N-terminal groups, becomes, by this and other examples (cf. α-melanophore-stimulating hormone below), of less and less significance.

Methods. The new methods which have been used so successfully for the separation of proteins, large and small peptides, and amino-acids were discussed by A. Tiselius, J. Porath, J. Borman, S. Moore, F. Turba, F. Šorm and B. Keil. In addition, L. C. Craig described a new and very simple microdiffusion apparatus which can be used not only for fractionation of dialysable peptides, but is also capable of giving information on the heterogeneity of the solute.

In retrospect, the Paris conference very clearly emphasized the great rewards that have accrued from the application of new and novel methods, and justifies the belief that any discussion of methodology should not be confined to a special symposium, but related over a very wide field to the major advances which have been made in our knowledge of the protein molecule.

KENNETH BAILEY

NEWS and VIEWS

Photograph of the Track of the Artificial Earth Satellite

THE Russian artificial Earth satellite is accompanied in its orbit by the remains of the last stage of the rocket from which it was launched. The rocket is at present travelling ahead of the satellite, at a distance which is increasing with time as the relatively greater resistance encountered by the rocket from the Earth's atmosphere causes it to fall to a lower altitude than the satellite. A photograph of the rocket, which is larger and more easily seen than the satellite itself, was taken at Hobart, Tasmania (42° 54′ S., 147° 20′ E.), at approximately 0938 G.M.T. on October 7, by Mr. T. McMahon, head of the Photographic Section in the University of Tasmania, working with members of the Department of Physics. Prof. A. L. McAulay, of the University of Tasmania, writes: "It shows the track of the rocket (Fig. 1) travelling approximately south-south-west to north-north-east against a background of stars of the constellation Aquarius".

Crystallography at the Swiss Federal College of Technology: Prof. J. D. Dunitz

Dr. J. D. Dunitz, who has been appointed to a chair of crystallography at the Swiss Federal College of Technology, Zurich, has had a distinguished career in the field of crystal and molecular structure studies. After graduating with first-class honours in inorganic and physical chemistry at Glasgow in 1944, he joined the research team of Prof. Monteath Robertson and carried out some very accurate structure determinations on the acetylene dicarboxylic acids. Later at Oxford, with a Carnegie Senior Scholarship, and at Pasadena, with an A. A. Noyes Fellowship, he extended his work to more complex organic compounds including certain important antibiotics. While holding later appointments at the National Institutes of Health, Bethesda, and at the Royal Institution in London, he has continued to make contributions to the field of complex natural products and proteins. Dr. Dunitz's interests, however, are not confined to these problems of complex structures, and he has made several important contributions to the structural chemistry of simple inorganic molecules, and in collaboration with Dr. Orgel he has written a number of important theoretical papers. These deal with the effect of chain-length on symmetry of conjugated molecules, with the stability and structure of the molecular sandwich compounds (dicyclopentadienyl iron) and other topics. In his new and important post at Zurich Dr. Dunitz will have ample opportunity to enlarge and extend his many interests in modern structural chemistry and crystallography.

American Institute of Physics: Compton Gold Medal

On behalf of the American Institute of Physics, H.R.H. Prince Philip conferred the first Compton Gold Medal of the Institute on Dr. G. B. Pegram, vice-president emeritus of Columbia University, for distinguished service to physics. The ceremony, which occurred in conjunction with the dedication of the new building of the American Institute of Physics at 335 East 45th Street, New York (see *Nature*, 179, 1167; 1957), was held before a group of distinguished scientists, educators and administrators in the Karl Taylor Compton Memorial Room of the new Institute on October 21. Dr. Pegram was a founder member of the American Institute of Physics in 1931, together with the late Dr. K. T. Compton and others. He served as its first secretary for fourteen years and was treasurer for eighteen years until he retired last year. Dr. Pegram also was an officer of the American Physical Society for thirty-eight years, serving as president and treasurer. He made the first contact with the United States Government in March 1939 which resulted in the Manhattan Project, after J. R. Dunning and the late Enrico Fermi had demonstrated the release of energy by uranium fission at Columbia University.

Dr. S. Fred Singer

Dr. S. Fred Singer, associate professor in the Department of Physics, University of Maryland, is to receive a United States Junior Chamber of Commerce award as one of the ten outstanding young men of the year 1957 whose achievements have been of importance in their professions and also to the general welfare of the United States. Dr. Singer has contributed to the study of rocketry and astrophysics as the leader in design and development of three small, inexpensive rockets for upper-atmosphere research. These are the 'Rockaire', the first high-altitude research rocket launched from aircraft; the 'Terrapin', the smallest high-altitude rocket launched from the ground; and the forthcoming 'Oriole', a ground- or ship-launched rocket which will be even less expensive and smaller. Dr. Singer has completed the design and construction of instruments for the detection of cosmic rays, to be installed in rockets to be fired in the current 'Far Side Project'.

President of the Royal Australian Chemical Institute: Dr. I. W. Wark

Dr. I. W. Wark, chief of the Division of Industrial Chemistry of the Commonwealth Scientific and Industrial Research Organization, has been elected general president of the Royal Australian Chemical Institute for 1957–58. Dr. Wark has been chief of the Division of Industrial Chemistry since its formation in 1940. Under his guidance this laboratory has grown until it now has a research staff of one hundred. Among its achievements are the process using cetyl alcohol for controlling evaporation from dams and reservoirs and a method for separating hafnium from zirconium which is of significance for atomic powered submarines. Dr. Wark's own personal research was concerned with the theory of the flotation process for separating minerals from ores. His pioneering work as a physical chemist in this field gained for him a wide reputation and his book "Principles of Flotation", first published in 1938, became recognized as a classic on the subject. He graduated at the University of Melbourne and continued his postgraduate studies at the Universities of London and California. Dr. Wark is a Fellow of the Australian Academy of Science. For many years he has taken a prominent part in the affairs of the Royal Australian Chemical Institute and has done much to gain a wider appreciation of the importance of chemistry and of science generally.

A Regional Museum Service

About twenty-five years ago the museums and art galleries of Great Britain were grouped together on a regional basis for friendly advice and help. It was a type of unofficial co-operation and each member of a group or federation was completely autonomous but could rely on fellow-members for help if desired. The Museums Association now considers that this service should be placed on a more regularized basis and proposes as an experiment to endeavour to set up a regional museum service in the south-west of England. It is considered that such a service would be helpful in the identification of material, the conservation of objects, and the organization of work with the schools. As a first step towards the initiation of such a service a meeting of local authorities and other interested bodies was held at Taunton on October 15 under the chairmanship of Sir Mortimer Wheeler. The meeting was enthusiastic concerning the value and worthwhileness of such a scheme and the only doubts raised were those involving finance. After careful consideration of the factors involved, it was decided to form a committee of inquiry consisting of four representatives of the county councils, four from the municipalities, four from the South-Western Group of Museums and Art Galleries, two from the Museums Association and one from the universities within the area of the counties of Bristol, Cornwall, Devon, Dorset, Gloucestershire, Monmouthshire, Somerset and Wiltshire. This committee was duly elected and requested to report back as soon as possible.

Annual Relief Voyage of R.R.S. *John Biscoe*

THE R.R.S. *John Biscoe* left Southampton on October 21 on her annual relief voyage to the Antarctic with staff and supplies for the Falkland Islands Dependencies Survey. The Survey maintains eleven permanent bases along the coast of Graham Land and on islands off the coast. Eighty or so scientists and technicians spend periods ranging from a year to two years at the bases, carrying out surveys, scientific research and meteorological work. Each Antarctic summer, between November and March, the ice of the Antarctic clears sufficiently for specially strengthened ships to make the voyage to the bases with relief staff, supplies and equipment. The present R.R.S. *John Biscoe* was built for this work. On her way to Port Stanley, she will call at St. Helena and Tristan da Cunha.

Bibliography on Atomic Energy

A MOST useful bibliography of sources of information on atomic energy taken from a paper (*A.E.R.E.* Lib/Ll) is given in *Atom* (No. 7, 23; May 1957), the monthly information bulletin of the U.K. Atomic Energy Authority. The bibliography covers publications on the work of the Authority; lists issued by the Authority; general bibliographies; four abstract journals; fourteen British and Commonwealth, nine American, and eight European periodicals and translated versions of Russian periodicals. A more limited bibliography (*A.E.R.E.* Inf/Bib 100. Harwell: Information Office, A.E.R.E., Harwell), which has recently been reprinted with additions, lists books published in Great Britain on nuclear energy, nuclear and atomic physics, the measurement of radioactivity, isotopes, and some related topics. It includes both popular expositions and advanced texts written for the specialist, in addition to periodicals in the field of nuclear energy.

Research in Central Africa

THE seventh annual report of the Institute for Scientific Research in Central Africa (pp. 268. Bruxelles: Institut pour la Recherche Scientifique en Afrique Centrale, 1956) covers the year 1954 and, besides the Director's report and accounts showing expenditure of some 77 million francs, of which 50 million were spent on research at the various research stations, it includes a review by L. H. Vincke of the anti-paludism campaign in Africa south of the Sahara and summaries of papers published during the year by the staff or research workers associated with the Institute. The report records a major study of certain depopulated districts undertaken at the request of the Government of Ruanda-Urundi to determine the facts for a campaign against *Glossina* responsible for the trypanosomiasis causing the depopulation. Collection of anastomopathological material for neuropathological studies with reference to virus diseases continued at Lwiro, where work on nutrition expanded considerably, particularly biochemical studies on proteins and amino-acids in relation to the nutrition of native children. Observations on birds in the neighbourhood of Tshibati and Lwiro continued, and at Uvira on Lake Tanganyika extensive studies were made of ndekala, a pelagic fish intensively fished in Tanganyika. Besides numerous hydrological observations on the temperature and composition of the water of the lake at various depths, many purely geographical observations were made relatively to its depth in the region of affluents, seasonal variations in temperature, lacustra, etc. Solar observations also continued at Lwiro as well as ionosphere observations and measurements of solar radiation.

The Rings and Satellites of Saturn

IN a recent paper entitled "The Effect of the Saturnian Ring upon the Motion of the Satellites" (*Publ. Astro. Soc. Japan*, 8, No. 1; 1957), Yoshihide Kozai starts with the assumption that the ring-system of Saturn, composed of a number of small solid particles, consists of two concentric rings with uniform thickness and density, and then proceeds to determine the quantitative effect of the ring on the motion of the satellites. The *A*-ring is supposed to be limited by the radii of 20·02″ and 17·49″, seen at the mean least distance, and the limits of the *B*- and *C*-rings are placed at the distances 16·90″ and 10·49″. Observational data are presented for comparison with the theory, and the values of the mean motions are computed on the assumption that $k/a^2 = 0\cdot024305$, $1/a^4 = 0$ for the six inner satellites of Saturn. From the solution of the normal equations it seems probable that the mass of the ring is of the order 10^{-4} that of Saturn. The precessional motion of the axis of rotation of Saturn is too slow to be detected, even from observations over about a century.

National Science Foundation Fellowships

THE U.S. National Science Foundation is offering four types of fellowship awards for advanced study and research in the natural sciences during the academic year 1958–59: predoctoral fellowships for college seniors and graduates (1,600–2,000 dollars a year); postdoctoral fellowships (3,800 dollars); senior postdoctoral fellowships for candidates who have held a science doctorate for a minimum of five years (up to 10,000 dollars); and science faculty fellowships for college teachers of science who wish to improve their competence as teachers (up to 10,000 dollars). The awards are open to American citizens and are tenable at any non-profit-making institution of higher education in the United States or abroad. Fellowships will be awarded in the mathematical, physical, medical, biological, engineering and other sciences, including anthropology, psychology (other than clinical), geography, certain interdisciplinary fields, and areas of convergence between the natural and social sciences. About a thousand awards will be made, to be announced next March. Fellows will be selected on the basis of ability assessed from letters of recommendation, academic records and other evidence of attainment. Applicants for the predoctoral fellowships are required to take the Graduate Record Examination. Forms of application for predoctoral fellowships, which must be completed by January 3, 1958, and for postdoctoral fellowships, which must be completed by December 23, 1957, may be obtained from the Fellowship Office, National Academy of Sciences—National Research Council, 2101 Constitution Avenue, N.W., Washington 25, D.C. Forms of application for senior postdoctoral and science faculty fellowships, which must be completed by January 13, 1958, may be obtained from the Division of Scientific Personnel and Education, National Science Foundation, Washington 25, D.C.

Gas Chromatography Symposium

The second symposium on "Gas Chromatography" will take place at the Tropical Institute, Amsterdam, during May 19–23, 1958. The meeting is being organized by the Gas Chromatography Discussion Group under the auspices of the Hydrocarbon Research Group of the Institute of Petroleum, and the Koninklijke Nederlandse Chemische Vereniging. It is intended that the programme shall be divided into three sections: *A*, theoretical; *B*, apparatus and techniques; *C*, applications. The official language at the symposium will be English. Original contributions and a 250 word abstract (two copies) should be submitted to the Secretary before November 20. Those papers describing applications of the techniques should have some novel feature. Application for registration must reach the Secretary before March 1, the fee being approximately 45 guilders, which will include the cost of preprints and receptions. Further information can be obtained from the Secretary, G. Dijkstra, Unilever Research Laboratory, Veersingel, Vlaardingen, Netherlands.

Bedson Club

The thirty-first annual general meeting of the Bedson Club, King's College, Newcastle on Tyne, was held on October 18. The programme of Bedson Lectures during 1957–58 will be: November 1, Dr. Dorothy Crowfoot Hodgkin, "The Structure of Vitamin B_{12}"; November 22, Prof. A. J. Birch, "Recent Studies in Relation to Biosynthesis"; January 31, Dr. J. W. Linnett, "The Structure of Flames"; March 7, Dr. H. Seligman, "Use of Radioactive Materials in Industry".

The Night Sky in November

Full moon occurs on November 7d. 14h. 32m. U.T., and new moon on November 21d 16h. 19m. The following conjunctions with the Moon take place: November 19d. 03h., Jupiter 3° N.; November 25d. 14h., Venus 8° S. In addition to these conjunctions with the Moon, Mercury is in conjunction with Antares on November 17d. 13h., Mercury being 2·7° N., Jupiter with Spica on November 21d. 17h., Jupiter being 3·4° N., and Mercury with Saturn on November 21d. 21h., Mercury being 3·6° S. There will be a total eclipse of the Moon on November 7, invisible at Greenwich. Mercury is too close to the Sun for observation. Venus sets at 18h. 20m., 18h. 35m. and 18h. 55m. at the beginning, middle and end of the month, respectively; during this time its distance from the Earth decreases from 75 to 53 million miles, the visible portion of the apparent disk from 0·578 to 0·428, and its stellar magnitude from − 3·9 to − 4·2. It is a brilliant object in the south-west after sunset; greatest eastern elongation is on November 18. Mars rises at about 5h. 40m. throughout the month; it is visible in the south-east just before sunrise. Jupiter rises at 4h. 55m., 4h. 20m. and 3h. 35m. at the beginning, middle and end of the month, respectively; it is near Spica. The stellar magnitude of Jupiter is − 1·3, its distance from the Earth on November 15 being 585 million miles. Saturn appears too close to the Sun for observation. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: November 9d. 19h. 13·9m., 97 Tau. (*R*); November 14d. 0h. 24·7m., A^2 Cnc. (*R*); *R* refers to reappearance. The Taurid meteors are active during November 1–10 and the Leonids during November 15–17, but conditions are not favourable for observation.

Announcements

Dr. A. D. Merriman, who has been registrar-secretary of the Institution of Metallurgists for the past ten years, is to retire at the end of this year. He will be succeeded on January 1, 1958, by Mr. R. G. S. Ludlam, who has been assistant registrar in the University of Leeds since 1951.

The Faraday Society Bourke Lectures will be given by Prof. W. Jost, of the University of Göttingen. The lectures are: "Reactions in Detonations and Shock Waves", to be given in the Lecture Theatre of the Department of Physical Chemistry, University of Cambridge, Free School Lane, on October 28, at 4.30 p.m. (chairman, Prof. R. G. W. Norrish); "Flame Reactions", to be given in the Lecture Theatre, Inorganic Chemistry Laboratory, South Parks Road, Oxford, on October 31, at 5 p.m. (chairman, Mr. R. P. Bell); and "Crystal Defects, especially near Phase Transitions", to be given in the Main Lecture Theatre, Chemistry Department, the Imperial College of Science and Technology, London, on November 4, at 5 p.m. (chairman, Sir Eric Rideal).

The autumn meeting of the British Society for Immunology will be held at the Wellcome Foundation, 183 Euston Road, London, during November 15–16. The first day will be devoted to a symposium on "Immuno-hæmatology" from 10 a.m. (chairman, Prof. J. V. Dacie).

The Institute of Physics (London and Home Counties Branch) has organized a Symposium on "The Design of Physics Research Laboratories" to be held at 2.30 p.m. on November 27 in the Lecture Theatre of the Royal Institution, 21 Albemarle Street, London, W.1. Admission is by ticket, obtainable from the Institute of Physics, 47 Belgrave Square, London, S.W.1, to which all inquiries should be made.

The Institute of Biology is arranging a second international symposium on "Freezing and Drying", which will be held in the Beveridge Hall, Senate House, London, W.C.1, on April 1 and 2, 1958. Further information can be obtained from the Secretary, Institute of Biology, 41 Queen's Gate, London, S.W.7.

The Eighth Canadian High Polymer Forum will be held at MacDonald College, Quebec, Canada, during May 12–14, 1958. The meeting is sponsored by the National Research Council of Canada and the Chemical Institute of Canada and will cover all aspects of polymer science. Further information can be obtained from Dr. L. A. McLeod, Research and Development Division, Polymer Corporation, Ltd., Sarnia, Ontario, Canada.

At the annual general meeting of the British Society of Rheology, held at the University College of Swansea on September 19, the following elections were made for the year 1957–58: *President*, Prof. E. G. Richardson; *Hon. Secretary*, Mr. N. Wookey; *Hon. Treasurer*, Mr. D. W. Jopling; *Hon. Editors*, Dr. E. W. J. Mardles and Dr. J. C. Vernon; *New Members of the Committee*, Dr. M. F. Culpin, Dr. A. Jobling and Mr. G. H. Tattersall. Information concerning the Society can be obtained from the Hon. Secretary, 52 Tavistock Road, Edgware, Middlesex.

SOIL MECHANICS AND FOUNDATION ENGINEERING

FOURTH INTERNATIONAL CONFERENCE

PERHAPS the most outstanding development in modern civil engineering practice has been the remarkable growth in the science of soil mechanics during the past thirty years. The publication in 1925 by Prof. Karl Terzaghi of his book "Erdbaumechanik auf Bodenphysikalischer Grundlage", in which he described his researches into the consolidation and shear strength of soil, is generally regarded as marking the beginning of the scientific study of soil as material of engineering interest. There followed a period of increasing interest in the subject, evidenced in Great Britain by the establishment in 1933 of a soil mechanics laboratory at the Building Research Station at Watford, Hertfordshire.

The year 1936 marked an important stage in the development of this new science, since in that year the first international conference was held at Harvard University, and this led to the formation of the International Society of Soil Mechanics and Foundation Engineering, with Prof. Terzaghi as the first president.

Since the end of the Second World War the International Society has gone from strength to strength, and there are now thirty countries represented in the Society as well as many private members from other countries. Following successful conferences at Rotterdam in 1948 and at Zürich in 1953, the largest and most successful, the fourth, took place in London during August 12–24 at the Institution of Civil Engineers, at which some 750 delegates were present.

Following the opening of the Conference by Sir Arthur Whitaker, president of the Institution of Civil Engineers, Prof. Terzaghi delivered an address to the Conference in which he developed the theme of his opening speech to the Zürich Conference, namely, that the application of soil mechanics to civil engineering problems, in spite of the advances in the knowledge of the properties of soils, will never be a matter of precision because of the variability in the properties of soils occurring in most strata, and must ultimately depend upon the skill and imagination of the engineer.

Some 189 papers were submitted, and in the light of experience gained at previous conferences these were placed into six divisions: (1) soil properties and their measurements; (2) techniques of field measurement and sampling; (3) foundations of structures; (4) roads, runways and rail-tracks; (5) earth pressure on structures and tunnels; (6) earth dams, slopes and open excavations.

There were nine technical sessions each of three hours duration, two being devoted to the subject-matter of division 1 and three to that of division 3, in view of their especial interest. Each session followed a similar course in which a general reporter opened the proceedings by summarizing the main conclusions he had drawn from reading the papers contributed to the particular division with which he was concerned, and he was followed by individual contributors to the discussion of the papers by members of the Conference. On the whole, the discussions were of a high standard and very stimulating, as was demonstrated by the high level of interest maintained by members throughout the week and a half of what must be admitted to have been a somewhat exhausting programme.

It was abundantly clear from the Conference that soil mechanics has a major part to play in civil engineering developments throughout the world, and it is natural that a considerable growth of interest in the subject is taking place in regions where there are large areas calling for development, as, for example, in Canada and the U.S.S.R.

The great increase in the amount of construction of high multi-storied buildings and other large structures has resulted in a corresponding growth of interest in the design of the foundations to carry heavy loads. Useful progress was reported in the development of methods of estimating the ultimate bearing capacity of foundations, but especial interest was shown in the problem of making accurate estimates of the settlement of structures founded on clays and other compressible soils. It appears that in spite of the many assumptions made in the method of estimating settlements based on Terzaghi's theory of consolidation, reasonably satisfactory agreement between the calculated and actual settlements is usually obtained for normally and lightly over-consolidated clays; heavily over-consolidated clays have been shown to need a special approach. A disappointment was the absence of any significant advance in obtaining a better understanding of secondary consolidation, which is the compression phase that occurs after the dissipation of the excess pressure of pore-water created by loading the soil.

In spite of improvements in the theoretical treatment of the bearing capacity of soils, the evidence from several papers indicated that serious discrepancies can occur between the actual and calculated values. This renders important the problem of how best to introduce a factor of safety into stability analyses. It emerged that there is now general agreement that the most rational method is to use a reduced value for the shear strength of the soil.

On the subject of pile foundations, practical evidence suggests that considerable confidence can now be placed in the methods used for estimating the load capacity of piles driven through soft soils to a firm granular stratum and of piles embedded in sand, but it appears that loaded piles embedded in soft clays are liable to significant settlements over long periods of time.

Another important application of soil mechanics is to the stability of slopes. This subject embraces natural slopes, which may be affected by sudden landslides or slow creep, excavated slopes such as cuttings for railways, roads and canals, and embankments, of which the most important example is earth dams.

Members of the Conference were given a graphical reminder of the devastation that can follow from a large landslide by a description by Mr. Fellenius of the great slides on the Gotha River in Sweden. Scientific studies are now frequently made of such landslides with the object of understanding more precisely the mechanics of the process. Of especial interest was the explanation by Prof. A. W. Skempton

(Imperial College of Science and Technology, London) of the reasons why London clay assumes a natural slope of 10 deg.

It was noted that very little effort is being devoted to the problem of the stability of excavated slopes. It appears that such slopes are often initially cut at a much steeper angle than is satisfactory for stability, and where large and costly cuttings are required, as, for example, for modern highways, a greater application of the principles of soil mechanics was advocated.

A session of the Conference was devoted to a discussion of earth pressures which determine the stresses acting, for example, on the linings of tunnels and on sheet piling and other earth-retaining structures. It is now recognized that in practice some yield of the structure almost invariably takes place, and the problem is then to make a reliable estimate of the distribution of stresses on structures in terms of this yield. Useful progress on this problem was reported in respect of both sheet piling and tunnels.

The rapid growth of traffic on the roads and the increased weight of aircraft have resulted in the need for thicker and stronger foundations for road and airfield pavements. This has rendered important the need for improved methods of pavement design in order that the most economical approach may be determined with some precision. Although the papers contributed to the Conference were scarcely representative of present thinking on this subject, it appears that reliance is mainly placed on empirical methods of design in which the estimated thickness of pavement is related for particular traffic conditions to the bearing strength of the soil measured by some form of penetration or loaded plate test. However, a trend was noted towards thinking in terms of a design method based on the moduli of deformation of the soil and pavement materials.

An understanding of the factors affecting the moisture conditions in soils under pavements is important because the moisture content largely governs the strength of the soil and hence the design of the pavements. While a satisfactory solution of this problem for humid climates has been developed in terms of the suction properties of the soil, it emerged that the part played by vapour transfer under more arid climatic conditions is not yet fully understood.

Quite apart from the consideration given to the physical properties of soil during the discussion of papers presented in division 1, the Conference was repeatedly brought back, during the sessions devoted to the more practical problems of foundation engineering, to the need for a better understanding of the fundamental factors governing these properties. There is now general recognition of the need to express shear strength in terms of effective stresses, and of the importance of making pore water pressure measurements both in laboratory tests and in field studies. These conclusions are, however, of principal value in their practical application to analyses of stability problems and do not help to any great extent in understanding the bases of soil strength.

Perhaps the most encouraging development at this Conference was the emergence of a body of support for the concept that many of the observed shear properties of soils can be satisfactorily explained in terms of internal normal stresses resulting from tensions in the pore water system. It was suggested that the development of this concept may well lead to the shear strength of soil being expressed in terms of a dimensionless coefficient of friction. Papers to the Conference also indicated useful advances in attempts to explain soil properties in terms of colloid chemistry and surface physics. Perhaps it is not too much to hope that by the time the next Conference is held a satisfactory hypothesis will have been developed that explains the part played by tensions in the soil water system and at the same time relates these tensions to the surface forces resulting from the interaction of clay minerals and water.

At the closing session of the Conference, members learnt with deep regret that Prof. Terzaghi had decided to relinquish the presidency of the International Society. The new president is Prof. A. W. Skempton, professor of civil engineering at the Imperial College of Science and Technology, London. It was also learnt that the offices of the Executive Committee had been transferred from Harvard University to the Institution of Civil Engineers in London, with Mr. A. Banister as secretary to the Committee. Paris has been selected as the meeting place for the next international conference.

During the Conference a number of technical visits were arranged to government, university and commercial soil mechanics laboratories and to sites of civil engineering interest. Receptions were held at the Tate Gallery, at the invitation of the chairman and members of the Public Works and Municipal Services Congress and Exhibition Council, and at the Hurlingham Club, and the Conference concluded with a banquet held at Grosvenor House. Following the Conference, many members joined short trips to various parts of the country to see works of civil engineering interest. D. J. MACLEAN

GAS CHROMATOGRAPHY

AN International Symposium on Gas Chromatography, sponsored by the Analysis Instrumentation Division of the Instrument Society of America, was held at the Kellogg Center for Continuing Education, East Lansing, Michigan, during August 28–30. H. J. Noebels (Beckman Instruments) was general chairman, and the programme was organized by V. J. Coates (Perkin-Elmer Corporation). The meeting was attended by about 350 people. Formal sessions were held in the mornings and evenings, leaving the afternoons free for informal discussions by small groups. This proved to be a very happy arrangement, as it allowed those with special interests to discuss fine points at length without holding up the main proceedings; I remember in particular a very lively triangular discussion between M. J. E. Golay, A. J. P. Martin and A. I. M. Keulemans on the usefulness of the theoretical plate concept. The formal meetings consisted of invited lectures, followed by a series of short contributed papers.

A large number of papers were concerned with the application of gas chromatography to specific analytical problems, such as arise in connexion with gasolines, ester-type plasticizers, chlorofluorohydrocarbons, glycols and piperazines. Many of the speakers commented on the savings in time and money which the new technique had brought to their companies. Other papers were devoted to detailed descriptions of apparatus and accessories (such as sampling devices and integrators), especially in connexion with commercial gas chromatographic equipment. As it is proposed to publish the full proceedings of the symposium in the near future, this report will be confined to those developments described at the symposium which seem to be of more immediate and general interest.

In the opening lecture, M. J. E. Golay (Perkin-Elmer) described his theoretical studies on the performance of a simplified gas–liquid chromatographic system, in which the liquid phase was held on the walls of a fine capillary. In such a system there should be no contribution to plate height (or peak spreading) from a channelling or 'eddy' term. Golay showed how the usefulness of such columns could be measured in terms of a 'performance index' (*Nature*, 180, 435; 1957), in which the drop in pressure across the column and the time for analysis are included as the price paid for sharpness of the peak. An account was given of some experimental work which had been undertaken to test the theory. The results were also of great practical interest, in that sharp separations (equivalent to about 10,000 plates) had been obtained with simple columns. Furthermore, it was found possible to run capillary columns extremely rapidly.

The behaviour of solid support materials was discussed by T. Johns (Beckman Instruments), and E. A. Hinkle and S. E. J. Johnsen (Monsanto Chemical Company, Texas City) showed how peak areas (using a thermistor detector) could be converted to molar concentrations by the use of vapour densities as correcting factors. C. S. G. Phillips (Oxford) described work using metal salts (in particular, zinc and copper stearates and nickel oleate) as column liquids. He pointed out that the strong forces between metal atoms and the ligand (solute) molecules made possible new types of separation. Changes in relative retention times up to several thousandfold in favourable cases (as, for example, with amines) could be obtained by this method. Such changes were also of value for the characterization of solute substances. He showed how the results with the metal salts columns could be related to studies of complex ion formation in aqueous solution, and how gas chromatography might thus be used for studying complexing equilibria. The use of gas chromatography in kinetic studies of the isomerization of geometrical isomers, the thermal decomposition of acetylene and the thermal decomposition of light hydrocarbons was discussed by L. F. Hatch (University of Texas), and in the study of the hydrogenation products of benzene by R. E. Rippere (General Electric Co.).

H. R. Felton (du Pont, Wilmington, Delaware) described a novel and compact high-temperature gas chromatography unit, in which the detector was a thermal conductivity cell using model-aeroplane glow-plugs. Sensitivity and response data for the unit were given from 40° C. to 550° C., and its use was illustrated by analyses of the fluoroesters of camphoric acid (boiling points 320° C.–460° C.), the α- and β-N-phenylnaphthylamines and the toluene isocyanates. The factors affecting the selection of thermistors for use in katharometers formed the subject of a useful study by P. H. Stirling and C. B. Cowan (Canadian Industries, McMasterville, Quebec), who stressed the importance of matching thermistors for resistance, resistance change with temperature and for dissipation constant. A copper oxide combustor as a means for increasing detector response was discussed by S. Norem (Perkin-Elmer).

One session and an invited lecture by B. O. Ayers (Phillips Petroleum) were devoted to the use of gas chromatographic instrumentation for continuous automatic analysis. Two commercial instruments (Perkin-Elmer and Leeds-Northrup) were described in some detail in the contributed papers. Ayers pointed out that a number of analysers were now available commercially, and that these instruments compared most favourably with other types of automatic analysers, especially in the wealth of data which they make available at a relatively low cost for the instrument. He described the testing of the Perkin-Elmer instrument on typical plant problems.

In a stimulating and entertaining after-dinner speech, A. J. P. Martin described his early work on separation techniques, in association with R. L. M. Synge and later with A. T. James, which led up to the discovery of gas–liquid chromatography. He commented on present trends in the field, the influence of gas chromatography on other techniques and its many possible applications. He concluded with some suggestions for the future of the method, including the development of the completely automatic analyst.

C. S. G. PHILLIPS

MACROMOLECULAR CHEMISTRY

INTERNATIONAL SYMPOSIUM

THE Macromolecular Commission of the International Union of Pure and Applied Chemistry broke entirely new ground this year by holding the tenth Symposium, on "Macromolecular Chemistry", in Prague. The success of this penetration into Central Europe and, for the Western countries, behind the Iron Curtain, is reflected in the record number of active participants housed in the Hotel International in the outskirts of the city in which the meetings, except for the opening session, were also held. This procedure lent an air of informality to the proceedings and, by keeping all participants in intimate contact with one another, fostered a feeling of friendly co-operation throughout the week.

No praise is high enough for the diligence, care and thoroughness with which the Organizing Committee, under the leadership of Prof. O. Wichterle, had laid its plans. Almost all the 200 papers and lectures were available in preprint form (Russian and Czech manuscripts were translated into English). To overcome the language difficulty still further, a very efficient cabinet translation service was in continuous session during the presentation of lectures and papers. All delegates were supplied with 10-channel transistor receiver head-sets which carried the translation service in Czech, Russian, French, English and German. This very fine piece of organization was much appreciated by all who took part and removed most of the strain of following complicated argument in a foreign tongue.

The matter of the Symposium was divided into two large sections dealing with (*a*) physics and physical chemistry of macromolecules and (*b*) polyreactions. These broad units were subdivided into smaller sections each dealing with a group of related problems in the field. The proceedings were initiated with a lecture by Prof. Paul Doty on "Biological Polymers".

This took the form of an exemplary review of the field to which the lecturer has made so many outstanding contributions. In the second Symposium lecture, Prof. H. Mark (Brooklyn) related with his usual enthusiasm and vigour the progress in polymer research and technology in the past year. His close contacts with the industrial and academic sides in the United States always make his lectures of very great interest and importance to European audiences.

Each of the sectional meetings was introduced by a lecture on a specific problem on the field. These lectures were later open to discussion, a feature which was novel to the Symposium but produced much of interest and importance. Both lectures and discussion are to be published in *Chemické Listy* and in *Collection of Czechoslovak Chemical Communications*. Prof. A. Peterlin (Ljubljana) introduced the group discussing statistics, thermodynamics and kinetics, with a lecture on the excluded-volume effect on the properties of macromolecules in solution. The properties of macromolecules in solution have long been the province of the Strasbourg school, so that it was fitting that the two sessions of this section were addressed respectively by Prof. H. Benoit, on the problems posed by polydispersity and molecular anisotropy in light scattering, and by Dr. R. Cerf, on the flow birefringence of macromolecular solutions. Prof. A. V. Kargin (Moscow), who dealt with structure and phase-state of polymers, discussed in detail the results of electron and X-ray diffraction and electron microscopy studies of 'Terylene', polytrifluorochloroethylene polyethylene, nylon and caprolactam polymers. Prof. F. A. Muller (Hamburg) in the same section concentrated on the deformation behaviour of polymers, especially under great deformation.

The biggest of the smaller sections dealt with the subject of radical addition polymerization, to which four sessions were allotted. In the first of these Prof. S. S. Medvedev (Moscow) gave a critical review of the present ideas of the mechanism of emulsion polymerization, a topic on which his own views tend to be at variance with the generally accepted theory of Smith and Ewart. Prof. G. V. Schulz (Mainz) described, in detail and with numerous illustrations, the use of polymerization as a test reaction for investigating the kinetics of radical reactions. In recent years the use of high-energy radiation, particularly gamma-radiation, has been exhaustively investigated as a method of initiating polymerization. It was particularly fitting that Prof. M. Magat (Paris), a pioneer in this field, should open the session dealing with this type of work. The problem of the kinetics of high-conversion reactions was treated by Prof. G. M. Burnett (Aberdeen), who reviewed past work and suggested an empirical approach which appeared to fit the experimental data. The section dealing with ionic mechanisms was addressed by Dr. D. C. Pepper (Dublin), who analysed in critical detail the various steps in the polymerization process and directed attention to the importance of ionic intermediaries in the polymerization of cyclic imines and oxides. Under the heading of other mechanisms of polymerization Prof. K. Zeigler (Mullheim) and Prof. F. Danusso (Milan), respectively, spoke on the use of organometallic compounds in the production of high polymers and on the kinetics of stereospecific polymerization. These papers occasioned much discussion, thereby underlining the wisdom of choosing specifically this field for the next Symposium, to be held at Nottingham in 1958.

The contribution of the host country was made by Prof. O. Wichterle (Prague), in a discussion of the polymerization of caprolactam which included valuable remarks on likely future trends. Prof. R. Simha (New York) tackled the extremely difficult task of attempting a unified hypothesis to explain the great divergences encountered in the pyrolysis of macromolecules. He approached the problem along the lines he has already successfully exploited, and was able by extension of previous methods to put forward convincing conceptions of the mechanism of the reaction. Interaction of polymeric molecules with organic reagents has for long been neglected but, with the rise of the importance of achieving modifications in the shape of graft and block copolymers, this field has now become more widely recognized. Under this heading Prof. W. Kern (Mainz) and Prof. G. Smets (Louvain) contributed interesting and valuable reviews of the current situation. Somewhat strangely in the context of so much discussion of synthetic polymers, the reactions of natural macromolecules such as proteins, nucleic acids and polysaccharides were considered. This section was introduced by Prof. H. Morawetz (New York), who concentrated on some specific effects encountered in polyelectrolyte solutions. The high density of charge along the macromolecule is of great moment in elucidating many of the effects of complexing with counter ions and the like. The extension of such observations from the synthetic to natural polyelectrolytes is likely to be very important. A new section in the symposium was devoted to the inorganic high polymers. The lecturer in this section, Prof. E. Thilo (Berlin), considered in particular the phosphates and silicates. Indeed, most of the section contributions tended to be directed towards these compounds.

Within the compass of a brief review such as this it is not possible to consider, even in passing, the many contributions to the proceedings, nor is it feasible to attempt an objective selection of the more important papers. Altogether some 180 papers were presented, and it is indicative of current lines of investigation to consider these under group headings. The largest groups were those dealing with solutions (34 contributors) and with radical polymerization (30 contributors). Properties of gels, melts and solids, and condensation polymerization (including ring monomers), each claimed 24, and natural large molecules, including proteins, nucleic acids and polysaccharides, had 29 contributors. The remaining groups obviously had few contributors, but in common with the more popular sections the standard of the contributions themselves and also of the ensuing discussion was high.

On a national level the distribution of papers is equally interesting. Contrary to expectation, perhaps, the leading nation was Germany (taking East and West Germany together) with 40 contributions, followed by the U.S.S.R. (31); France (28); Czechoslovakia (25); the United States (17) and Great Britain (16). At the same time the number of papers submitted does not reflect the actual attendance at the Symposium since, for example, the 150 Russians present formed the biggest single group. They were led by Prof. N. V. Semenov, who contributed some interesting observations in discussion.

Outside the conference halls the hospitality of the hosts left nothing to be desired. After the lengthy sessions of the day, entertainment in the evenings was lavish and spectacular, with a deliberate flavour of national pride. Alternative entertainment was normally provided, also showing the culture of the country. The high-lights of the week were probably the performance of Dvorak's "Rusalka" in the National Theatre and the traditional Symposium dinner in the Wallenstein Palace.

In retrospect one can sum up the Symposium as being one of the most successful yet held and certainly the best organized. The standard which was set is one which will be found difficult to equal, but it is hoped that something approaching this technical perfection will be reached in other countries, both west and east of the Iron Curtain, in future international symposia.

THE LIBRARY ASSOCIATION

ANNUAL CONFERENCE

IN his presidential address to the Library Association on September 17 on the theme of "Knowledge and Education", Dr. J. Bronowski said that a civilized society must preserve what its best minds discover, but preservation alone does not make it an educated or even a cultured society. Moreover, an educated society could exist only when knowledge is not merely stored but is also shared, and it was the invention of printing that made the book an instrument of education. Dr. Bronowski drew on his own experience to illustrate the role that libraries can take in education and above all in self-education, but in science the public libraries have scarcely played that part at all: if they are to do so, they must have the books to enable them to make the language of science familiar to those who are not professional scientists. Besides the classics of literature, we need many more new classics of science—books like those of Sherrington, Eddington and Schrödinger, which looked at new discoveries in a personal way and spoke to the non-scientist through their personal tone and philosophy. He urged the publication of the old and new classics of science in a single series, which he believed would be widely bought and read and would make the language of science familiar to a new generation, showing them the concepts of science for what they are, classical creations which rank among the permanent monuments to the human imagination. He did not think that the printed book was the last instrument of education we would discover, but he was sure that the printed book and the public library would remain the most powerful means for self-education.

Dr. Bronowski's address found echoes in several of the addresses which followed. Mr. A. Shaw Wright's review of the thirty years work of the County Libraries Section of the Library Association, in referring to the work of the regional bureaux, to the "Readers' Guides", to the international exchanges of assistants and the help of the Carnegie United Kingdom Trust, indicated also the way in which the county libraries contributed to this work of self-education. It was implicit also in the discussion of the problems of the school library which Mr. E. Blishen introduced under the title "The Reluctant Reader", and it was sounded explicitly by Mr. J. C. Harrison in his "Retrospect and Forecast of Education for Librarianship and Professional Status". Admittedly controversial on some points, Mr. Harrison made a strong plea for well-educated and trained librarians if the public library is to be an effective instrument of education, and he claimed that at present it offered neither the status nor the remuneration which could attract or hold a sufficient number of those possessing the ability and knowledge required.

Dr. T. A. Margerison took up more specifically Dr. Bronowski's point in discussing the interpretation of science in an address to the reference and special libraries section on September 19. Dr. Margerison asserted that the average layman's ignorance of science was a danger to democracy, and stressed the need for more effective science teaching in the schools, for more writing for the layman by scientists of repute, and for more effective advice to librarians on the choice of scientific books. Mr. B. S. Page in reviewing university library development was concerned with a particular aspect, but his paper is of special interest to the scientist as such. Recalling the assertion of the University Grants Committee in its report of 1921 that an adequate library is not only the basis of all teaching and study but also an essential condition of research, Mr. Page discussed the implications for the university library of the post-war expansion of the universities. The two-fold function of the university library, of supporting both the teaching of the undergraduates and the creative work in scholarship or science of the postgraduate students and the university staff, was not at all easy to balance. Mr. Page emphasized the importance of the library representing to all, and not least to undergraduates, the unity and not the fragmentation of knowledge. The whole question of training the student in the use of the library required more study, and Mr. Page referred to the investigation into the adequacy of present library techniques to the needs of scholarship initiated by the Ford Foundation, and to the pilot survey which the Nuffield Foundation was conducting at Leeds in the use of books in a university library. Stressing the importance of the initiative of the library in connexion with general education, Mr. Page suggested that the university library should include a centre of disinterested reading, looking and listening, and that the right kind of help and the right atmosphere were what the student needed. On the expenditure side, Mr. Page said little. He pointed out that according to the University Grants Committee's returns for 1955–56, fifteen universities and university colleges spent on books and bindings a total of £214,586, or about the amount spent by Harvard University alone, the total for England, including Oxford and Cambridge, being £487,786, but he did not attempt to analyse expenditure or holdings in relation to expansion.

Of the remaining papers, Dr. C. W. J. Higson's review of the libraries of the university institutes of education should be mentioned.

STRIVING FOR RIGOUR IN GREEK SCIENCE

IN an address delivered at Dublin to Section A (Mathematics) of the British Association, entitled "The Striving for Rigour in Greek Science", Prof. C. Lanczos compared the standards of mathematical rigour set by the Greeks with the standards of to-day, and examined their claims to be regarded as complete in terms of the general Greek philosophical background. In particular, it is to be remembered that to the Greeks geometry was not a professional or technical craft, but "a divine service, pursued by the select minds who could face the shadowy world of abstract ideas".

The pattern of Greek geometry has a three-fold basis: definitions, axioms, postulates. Definitions are intended to tell us what we are talking about; axioms give the fundamental and general basis of philosophical language; postulates, which ask for certain propositions to be granted, are assumptions special to geometry. The distinction between axioms and postulates was clear to the Greeks, who properly based the theory of parallels on a postulate rather than on an axiom, but later workers confused the issue: Prof. Lanczos considers that Kant's philosophy is partly defective because he placed axioms and postulates on the same footing. The present view of mathematics as a language and of deduction as a game with symbols again implies a three-fold basis of undefined elements, definitions and rules. The difference, according to Lanczos, is chiefly one of emphasis; to the Greeks, mathematics was an abstract language describing real things, to us mathematics is a language which need not have a physical meaning. Only if a correspondence can be set up between mathematical words and physical objects does a physical meaning emerge.

In dealing with limits, Prof. Lanczos notes that in the theory of irrationals due to the great Eudoxus, the method of exhaustion uses sequences of inequalities and avoids infinitesimals and equations involving infinitesimals. The dangers of the concepts of Newton and Leibniz, so caustically exposed by Berkeley, do not arise. The Greek method, when allowance is made for the difference between their geometrical language and our algebraic language, is precisely that recovered in the early nineteenth century by Cauchy and Gauss, and developed during that century by Dedekind, Weierstrass and many others. The subtlety of the Greek genius is particularly well shown by the observation, attributed to Archimedes, that a hitherto undetected postulate is required in the method of exhaustion, namely, that if ϵ is any positive number, an integer n can be found such that $n\epsilon > 1$. It is, of course, now a commonplace that geometries can be constructed in which the Euclidean postulates hold, but in which the Archimedean postulate is not fulfilled.

Prof. Lanczos's conclusion is that contemporary mathematics adds nothing essentially new to the high standards of Greek rigour.

FOOD INVESTIGATION, 1956

THE research with which the Food Investigation Board is concerned lies between primary production on one hand and nutrition on the other; it includes, therefore, studies on the biological structure of raw foodstuffs and the changes that occur during storage, preservation, processing and cooking. The Board recognizes two types of objectives in its investigations, the first being knowledge of the physical and chemical properties of various types of foodstuffs, while the second is of short range and is concerned with the solution of specific practical problems. This dual approach is well illustrated in "Food Investigation 1956"*, which contains the reports of the Food Investigation Board and of the director of the Food Investigation Organization.

In the former the importance of close collaboration between research stations and the industries concerned with implementing the results of the research is emphasized. With this end in view, the setting up of a meat research laboratory in close association with an abattoir is strongly recommended. The Board is satisfied that a proper balance is maintained within the Organization between fundamental and applied work for the attainment of ultimate practical objectives.

The Director's report gives details of work performed during the year in the various stations of the Organization; on fish and fish products at the Torry Research Station and Humber laboratory, on fruit, vegetables and plant products at the Ditton and Covent Garden laboratories, and at the Low Temperature Research Station in Cambridge on meat and meat products, eggs and poultry, as well as biochemistry and biophysics.

Work at Torry has continued on the effects of preservative ice containing chlortetracycline (aureomycin) on the keeping quality of fish. Full-scale trials were conducted on the Station's research vessel *Sir William Hardy*, and it was concluded that the presence of 5 p.p.m. of the antibiotic in the ice extended the storage life of fish in ice by seven to ten days. Food regulations in Britain at present do not permit such additions to ice, and considerable work is needed before this practice can indeed be shown to be harmless. Work has also been concerned with the cleanliness of fish boxes, which has been shown to affect the keeping quality of fish. Since cleaning and sterilizing of wooden boxes are difficult problems, trials with a non-returnable fish box of moulded resin-impregnated paper pulp have been continued. Basic investigations include studies on the proteins, lipids and extractives of fish flesh, and on the chemicals responsible for the development of brown discolorations during the dehydration of fish. The well-known sugar–amino-acid reaction is not, apparently, the only factor concerned. Other basic work has been on some of the physical factors that affect the deposition of smoke during smoke curing. The bacteriology section has continued its investigations on marine bacteria, and a type culture collection is maintained that is used by workers throughout the world.

In the Meat and Meat Products Division at the Low Temperature Research Station and the Smithfield laboratory, work has proceeded on the improvement of the quality of frozen beef and on the problem of carcass wastage, that is, the loss of weight of animals that takes place prior to slaughter. Basic work included a detailed study of normal *rigor* in animals and of the distribution of dipeptides within the muscles of various species.

A feature of the work of the General Biochemistry and Biophysics Division has been a study of the preservation of foods with ionizing radiations. This work, begun on a small scale in 1949, was resumed in 1955 and is now particularly directed to the treatment of meat. One of the main problems is that a dose of radiation sufficient to sterilize a foodstuff

---

[*] Department of Scientific and Industrial Research. Food Investigation 1956. Report of the Food Investigation Board with the Report of the Director of the Food Investigation Organization. Pp. 68. (London: H.M. Stationery Office, 1957.) 3s. 6d. net.

usually produces an unpleasant odour and flavour. Consequently radiation 'pasteurization', in which considerably lower dosages are required, seems to show more promise; the product, although not sterile, has an enhanced storage life at low temperatures.

Studies in the Fruit, Vegetables and Plant Products Division include work on nitrogen metabolism in fruit trees, on the organic acids in apples, strawberries and cherries, and on the respiration of apple tissue slices. Of a more immediately practical nature has been the work on the storage and transport of fruits and vegetables. Considerable success has been achieved with the transport of precooled strawberries in insulated containers with solid carbon dioxide suspended at roof-level, and in the use of nonyl alcohol as a sprout suppressant for potatoes. The Covent Garden laboratory has now increased its collection of coloured slides of disorders and diseases of fruits and vegetables to more than three hundred and fifty.

The volume concludes with details of the Food Investigation staff and a list of the ninety-four publications by members of the staff during the year. There is a complete index, and the report can be thoroughly recommended as a compact record of the results obtained and as a guide to the directions in which work is progressing in food research in Britain to-day.

P. L. PELLETT

THE MELLON INSTITUTE

REPORT FOR 1956

THE annual report of the chairman, M. B. Ridgway, to the Board of Trustees of the Mellon Institute for the year ended February 28, 1957, in which the Institute expended 5,187,353 dollars on fundamental and applied research, is entitled "Advantages from Research in Mellon Institute"*. Before describing the activities of the various research departments and fellowships, the report outlines the respective advantages of basic and applied research, following the Trustees' decision this year to cultivate extensive fundamental research, particularly on major problems of far-reaching importance to chemistry and allied sciences. Fifty-five members were employed in the six research departments, and 507 fellows and assistants were working in the forty-five multiple and twenty-four individual fellowships in operation during the year, while the servicing staff numbered 214. Of these fellowships, eight had been in operation for thirty-five years or more, six for twenty-five years, twelve for twenty, nine for fifteen and three for ten years.

In the Department of Research in Chemical Physics a new mounting device for carbon replicas, developed for orienting surface structures visible under the light microscope so that electron micrographs may be obtained, has been used for studying the complicated structure of cleavage surfaces in the amethyst. A reference intensity scale for visual comparison of the line intensity on a photographic emulsion has been developed for semi-quantitative spectrochemical analysis. Spectral evidence was obtained of tautomerism in diazo ketones and an X-ray diffraction method was developed for determining total crystallinity in elastomers which undergo preferential molecular orientation before crystallization.

In the Department of Research in Physical Chemistry the use of nuclear magnetic resonance spectra of adsorbed particles on silica and other absorbents is being investigated. Various organic liquids were separated by thermal diffusion and in the study of packed columns cellulose was substituted for glass-wool packing and further studies were made in the design and operation of a thermal diffusion column with a top reservoir. Work on the determination of branching in diene polymers was started.

In the Department of Instrumentation work continued on the evaluation and development of analytical balances and a new technique has been devised which involves modified arresting, mechanical handling of the weighed object and a new case design so that the whole operation can be performed automatically while a printed record is obtained. Rapid weighing at high temperatures is also being explored, while the Department of Applied Mathematics has worked at a series solution for large deflexions in simply supported disks under uniform loading. An investigation of combustion methods at high temperatures for the macrodetermination of carbon, hydrogen, sulphur and halogens in organic or metallo-organic compounds was initiated in the Department of Analytical Chemistry, where a procedure was devised for microdetermination of small amounts of residual carbon on inorganic catalysts, and the fundamental study of *Ferrobacillus ferroxidans*, the chemosynthetic autotrophic bacterium isolated from bituminous coal mines, was continued. The Department of Radiation Research, created in September 1956, is seeking to apply the radio-iodine scavenger technique to determine the nature of the free radicals produced in the radiolysis of organic materials.

Among the programmes of the Institute's continued fellowships may be mentioned a completed two-year investigation of the pulmonary effects of synthetic silicate materials, and investigations of the relation between the products of laboratory fermentations of vegetable matter and organic substances found in natural streams, using the carbon-filter technique, which indicate that the phenolic material consists of highly substituted single phenyl rings. Besides the preparation of anticarcinogenic agents related to bifunctional molecules, such as the nitro-mustards, and substances related to azaserine, the antimetabolites of *p*-hydroxybenzoic acid have been examined in a search for agents effective against typhoid fever, malaria and tuberculosis. Drugs effective against schistosomiasis and virus diseases have also been sought. Under the Amine Fellowship new or improved processes for the preparation and manufacture of more than fifty medicinals have been studied intensively, and improved methods have been devised for administration or pharmaceutical use of established drugs, including a granular form of aminophylline, while a 1 per cent aqueous solution of iodine, containing triethanolamine hydriodide as solubilizing agent, was found to be an efficient antiseptic and germicide with comparatively low irritant action on tissues.

The Multiple Fellowship on Power Rectifiers is placing increasing emphasis on the preparation and purification of silicon with a view of developing an efficient silicon rectifier, and has initiated a study on the formation of rectifying junctions in silicon by solid state diffusion and by alloying processes. Under the Computer Components Multiple Fellowship investigations were directed to a fundamental understanding of the parameters influencing the brightness characteristics of electro-luminescent phosphor screens. In addition to studies of the friction and lubrication of fine instruments, under the Watch Technology Fellowship properties such as thermal stability, low friction and wear, dimensional stability and good electrical properties over a wide temperature range are being sought in polymeric substances.

---

* Advantages from Research in Mellon Institute, 1956–1957. Pp. vi+54. (Annual Report Series, No. 44.) (Pittsburgh, Pa.: Mellon Institute, 1957.)

Other fellowships were concerned with heat losses through joints on high-temperature piping, due to expansion of the pipe and shrinkage of the covering, the high temperature viscosity of clays and the deleterious effect of balling in mixes used for dry-pressing refractories. Certain organic amines of high molecular weight reduced or eliminated balling of the clay by lowering its hydrophilic nature and plasticity, as little as 0·2 per cent on a small-scale plant trial reducing balling in a commercial mix by 50 per cent. The curious accelerative effects observed in an examination of the relaxative behaviour of silicon nuclear spins in silica-glass have been traced to a reaction between the silicon-spin system and the spins of hydrogen atoms present in silica through its contamination with some form of water, while considerable progress was made in determining the part which traces of contaminants play in sensitizing crystalline and glassy silica to the action of high-energy radiation. In attempts to develop an improved method for evaluating the mechanical strength of glass, evidence was obtained that the sodium–vapour technique may be a useful tool for detecting the existence of flaws invisible under ordinary optical examination. A basic study has been made of the nature of alkali attack on porcelain enamels, together with differential thermal analysis studies on such enamels and related ceramic chemicals. Deoxidation practices in basic welding processes and the way these effects may be used for influencing porosity and physical properties of metal deposited in arc-welding have also been investigated, as well as problems in building supersonic wind tunnels and the erection of the vessels for the full-scale nuclear-energy plant.

In a three-year-old evaluation of synthetic resin coatings on blast-cleaned and steam-cleaned surfaces, the systems alkyds, phenolics, vinyls and chlorinated rubbers have already exceeded the performance of conventional paints used as controls, and a new series of modified epoxide resins, the 'Capsulon' resins, complementary to the 'Stypols' in properties, is expected to find wide use in the electrical industry as impregnating, potting and casting materials. Satisfactory paper chromatographic procedures have been worked out for determining dihydric phenols and some of their derivatives, and by combining polarographic and infra-red data with chemical results, the surface chemistry of most carbon blacks has been characterized in terms of quinone and hydroquinone groups.

The report includes a general review of the achievements during the past forty-five years of the Petroleum Multiple Fellowship, which has carried out studies of the rates of oxidation of asphaltene fractions of several amides, the synthesis and properties of porphyrin–vanadium complexes, including the preparation of 2 : 4-dimethylpyrrole and 2 : 4-dimethyl-3-ethylpyrrole, as well as devising a method of structural group analysis for oils of high sulphur content and studying the mechanism of carbonium-ion formation over acidic catalysts.

The Bone Products Multiple Fellowship has done much development work on a new granular absorbent for corn syrup refining. Use of polyoses as ingredients of prepared adhesives from cheap starches and dextrins has evoked considerable interest. Work on methyl glucoside continued to show promise, and much attention was given to the development of a preweaving size for filament acetate, using various types of 'Excello' dextrins. Data obtained from filtration tests have been correlated to assist in specifying fabric-filter media for increased efficiency, versatility and useful life, while processes have been developed for applying powdered resins to the surfaces of man-made fibres to increase their resiliency and stiffness and thus give adequate resistance to water-pressure during immersion. Efforts to improve the quality of hydraulic brake fluids have met with continuing success. The mechanism of the ester-amide exchange between methyl fatty acid esters and alkanolamides was studied and the search for heat and light stabilizers for dispersion–resin systems has been intensified. Rheological studies on silicone polymers led to a theory of association and tanglement explaining the anomalous properties of linear high polymers.

THE FORESTRY COMMISSION

REPORT FOR 1955–56

THE first planting work carried out by the Forestry Commission after its inception in 1919 was undertaken at Eggesford Forest between Exeter and Barnstaple. In May 1956 the Queen, with the Duke of Edinburgh, visited Eggesford to unveil a commemorative stone recording the planting by the Commission of the millionth acre of forest in Great Britain. A new policy with respect to planting was published in a White Paper in 1943, but it did not come into force until 1947 and proved rather too ambitious in its proposals for the acquisition of land, and planting consequently suffered.

In the new programme, an area of 900,000 acres of planting in the first ten years was prescribed. A total of 548,000 acres has in fact been planted, or 61 per cent of that proposed. For acquisition an area of 850,000 acres was proposed; actually, only 493,000 acres were acquired. The planted area excludes that acquired as the Commission has on hand a considerable area of plantable land and considerable stocks of plants available. The acquisition of land is now the main problem. For years now 5,000,000 acres of forest has been considered the proper proportion for Great Britain, and the Commission still holds to this view*; but it need not be all Government forest if private owners play their part and maintain a correct forest management.

There is little doubt that there is adequate land of relatively low agricultural value and of the right planting type. The question is whether, at present, the acquisition of land is not regarded too much from the point of view of production of marketable timber to the exclusion of land which, though not unsuitable for the growth of trees, would produce timber of poor quality and slow growth. Such trees would nevertheless give valuable protection to neighbouring and more valuable land. Land acquisition is the problem, and the Commission is quite correctly unwilling to use compulsion ; nor would such action further the purpose in view. Rather, the co-operation of owners and occupiers of hill land is sought.

---

* Forestry Commission. Thirty-seventh Annual Report of the Forestry Commissioners for the year ended 30th September, 1956. Pp. 94+4 plates. (London: H.M. Stationery Office, 1957.) 4s. 6d. net.

Private planting has been more encouraging, and for the year 1956 for the first time the area planted privately, namely, 27,100 acres, exceeded the programme of 25,000 acres proposed in the White Paper. For the first decade of the period covered by the policy outlined in the White Paper, private owners planted 165,000 acres, as against the 200,000 acres proposed in the programme. In the past three years private planting has steadily increased. The grants under the dedication scheme have been increased owing to the general increase in costs ; the planting grant has been raised from £15 to £17 per acre and the maintenance grant from 5*s.* to 5*s.* 6*d.* per acre. The thinning grant remains at £3 15*s.* per acre.

Special planting operations have been in force in crofting districts in the Highlands, where close liaison is maintained with the Department of Agriculture for Scotland and the Crofter Commission. From a report of a survey of mid-Wales, the trend toward a declining and ageing population is to be traced in a region of naturally low agricultural potential, and any development for improving agricultural conditions would result in the employment of still fewer people on the land. Many acres would degrade or fall out of production and should be available for planting by the Commission.

The markets for the thinnings, even small material, are becoming more favourable, and this should be an incentive to private planting. The protection of the forests from fire is still a matter of the gravest concern.

'ANGELS' ON CENTIMETRIC RADARS CAUSED BY BIRDS

By W. G. HARPER

Radar Research Station, Meteorological Office, East Hill, Dunstable, Bedfordshire

SINCE the inception of high-power centimetric radar, unexplained echoes have been observed which for want of a valid explanation have been termed 'angels'. They appear as small blobs on a plan-position display, are usually indistinguishable from echoes received from point targets, and occasionally occur in immense numbers. As output powers have increased, in pace with the requirements of aviation, the range of detection of these displays has also increased (reports have been received of widespread displays out to 80 miles), and they have come to present a hazard to airfield-control and military-type radars.

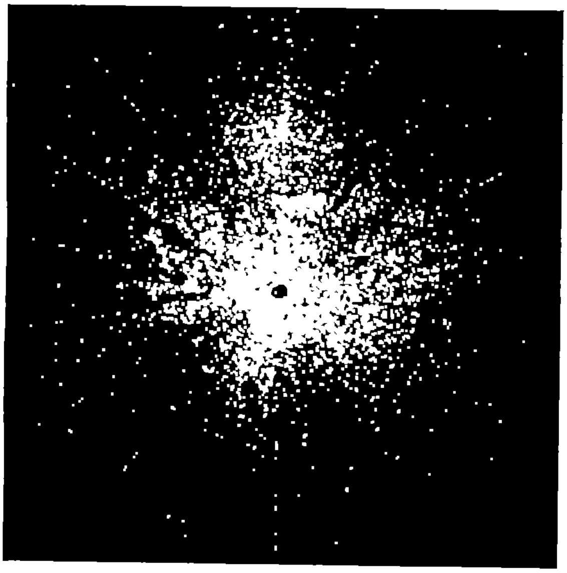

Fig. 1. Widespread display of 'angels' on 10-cm. plan-position display. Many appear as strong as echoes from aircraft. Range markers at 5-mile intervals

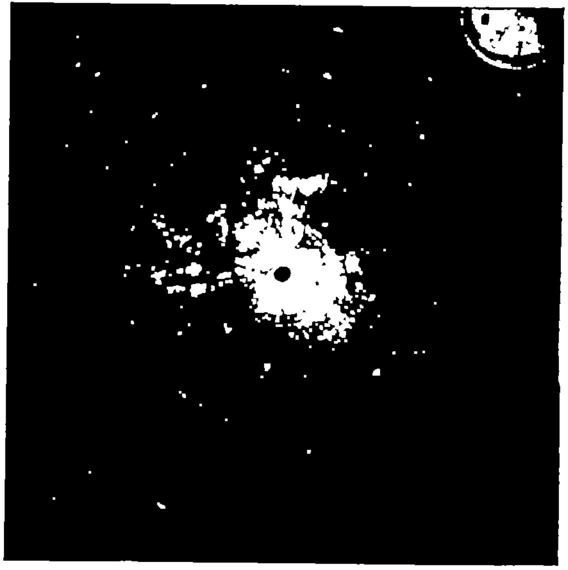

Fig. 2. Permanent echoes caused by rising ground, trees, buildings, etc., on the same scale for comparison. No 'angels' are present. The few stronger pip-echoes beyond 10 miles are from aircraft

As these effects have not been given wide publicity, examples are shown (Figs. 1 and 2) of photographic records made at East Hill, which is in open country close to the Chiltern Hills, 30 miles north-west of London. The equipment used was a 10-cm. plan-position display, peak power 500 kW., pulse-length 2 μsec., beam-width in azimuth 1½° to half power.

Lack and Varley[1] as early as 1945 reported that some point target radar echoes were caused by large sea birds, but it has generally been held that birds could not cause displays apparently spread uniformly over large areas. Insects have been considered[2], but

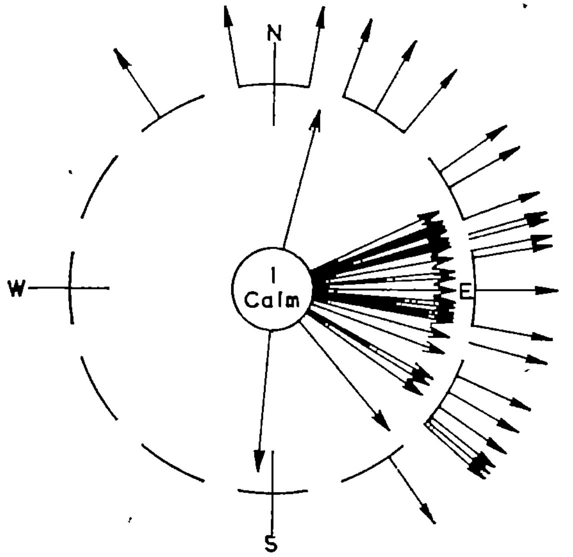

Fig. 3. Spring 'angel' movements (February–April) in inner zone. All available East Hill records (24 days in period 1952–57). Wind directions in outer zone

the widely accepted view is that radar 'angels' are primarily of meteorological origin[2,3]. Various theories have been developed invoking either reflexion at an interface, or refraction by meteorological elements containing steep gradients of refractive index, but no single theory has managed to explain more than a few of the observed properties of 'angels', and the theoretical requirements have in each case been so stringent as to be difficult of acceptance.

In searching for another approach to the problem, it was realized that the most intense occurrences were at the times of spring and autumn bird migration, and we have now found substantial evidence that even the densest of these displays of 'angels' may be caused by birds.

Interesting evidence is provided by the directions of movement of 'angels'. All available East Hill records of these in the months February–April are shown in the inner zone of Fig. 3 (we have many more recorded occurrences of 'angels', but in most there is no clue to the direction of movement).

Where the directions on any one day had a spread of values, for example, 060–085°, a single vector is entered against the mean value. All but two lie in the sector 060–140°. The wind directions at the levels of occurrence (derived from the nearest radar-wind soundings) are shown in the outer zone. They are prevailing west to south-west winds, in general agreement with the 'angel' movements, but are spread through almost twice as big an azimuth sector. It might be thought that the 'angels' only appear not to move with the wind because the radar-winds are unrepresentative, but we have examined the individual pairs of directions and find that many of the 'angel' movements have an undeniable and substantial crosswind component. The two inconsistent movements of Fig. 3 are examples of this: (1) The movement towards 185° occurred with a strong north-west wind on February 1, 1952. It suggests a 'weather movement' of wintering birds[4]; (2) that towards 015° occurred with a strong south-east wind which must have caused heavy lateral drift. Vector addition shows that birds drifted by this wind must in fact have been heading east-north-east, a normal direction of migration.

The autumn 'angel' movements (Fig. 4) are equally interesting. They are seen to be divided between south and west in a 160° sector, but the winds are strikingly variable. There are six days with winds between west and north-west, but not one case of 'angels' moving with these winds. It seems irrefutable that 'angels' of this type are not wind-borne.

These movements are quite inexplicable in terms of any proposed meteorological theory of 'angels', but are quite consistent with bird migration movements. Easterly movements in spring (Fig. 3) would be mainly departures of flocks of wintering birds to their breeding grounds in north-central Europe, followed by passage migration through southern England, while the concentration of southerly movements (Fig. 4), which are spread evenly throughout the four months, suggest birds bound for the Continent; the west-north-west movements, birds from northern Europe which winter in Ireland. Such movements in southern England have been extensively reported (for example, Lack[5]). Heavy October westerly movements of chaffinches (*Fringilla coelebs*), skylarks (*Alauda arvensis*) and starlings (*Sturnus vulgaris*) have been reported at Oxford, only 35 miles west-south-west of East Hill[6]. Five out of the six west-north-west 'angel' movements of Fig. 4 actually occurred in October, one in November, and we conclude that the west and west-north-west 'angel' movements are these same regular migration movements towards Ireland.

A noticeable feature is that 'angels' commonly move faster than the wind at their height, with speeds sometimes twice the wind or even more. We have made ninety-two measurements from radar of the ground-speeds of individual 'angels', spread over nine days in the period of spring migration, and have subtracted probable winds vectorially. The overall range of airspeeds derived, 22–56 m.p.h. (maximum concentration 33 m.p.h.), is in good agreement with recorded still-air flight speeds of common birds[7].

This evidence is admittedly inferential, but we have some direct evidence. When using a target-

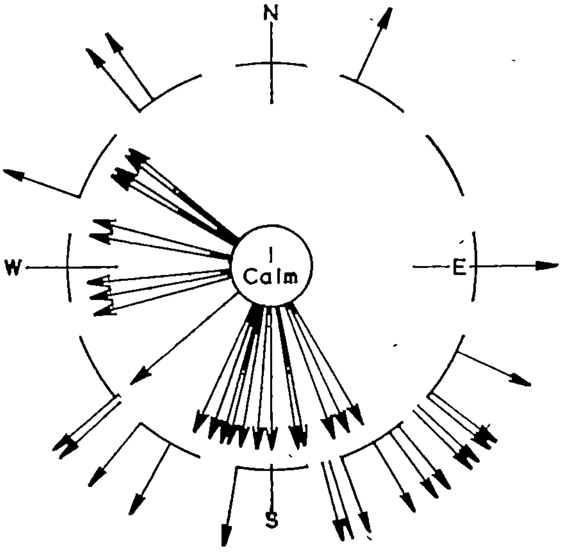

Fig. 4. Autumn 'angel' movements (September–December) in inner zone. All available East Hill records (22 days in period 1952–56). Wind directions in outer zone

tracking radar to track 'angels', on occasion of a widespread display, small flocks of birds have been detected in the field of a telescope fixed to the moving aerial. It was clear that the radar was following their flight, often through considerable changes in azimuth and elevation, and that each individual 'angel' was in this case the composite echo from one flock of 5–30 small birds.

It is hoped to publish more details of this work elsewhere, and to show that other aspects of the occurrence of 'angels', such as their seasonal distribution, and spread in altitude, also point to the conclusion that all widespread displays of 'angels' on centimetric radars in southern England are caused by birds. We can see no reason to invoke any other mechanism to explain them.

The permission of the Director-General of the Meteorological Office to publish this communication is gratefully acknowledged.

MOVING VISUAL IMAGES PRODUCED BY REGULAR STATIONARY PATTERNS

By Dr D. M. MacKAY
Physics Department, King's College, London, W.C.2

REGULAR patterns have a peculiar status from the point of view of information theory as being rich in 'redundant' information. Redundancy, despite the pejorative flavour of the word, is not always an undesirable property. In particular, it enables an information system in principle to transmit a message in the face of disturbances or 'noise' which would destroy a less-redundant transmission. To profit from redundancy in this respect, one must in effect reduce the number of degrees of freedom of the signalling system, thus increasing the informational efficiency, by 'recoding'.

These considerations suggest that in investigations of the visual information-system it might be specially interesting to observe the effects of highly redundant information patterns, since the nervous system might conceivably have its own ways of profiting from such redundancy.

As a first step in this direction, some simple stimulus figures have been constructed which fill an appreciable area of the visual field with highly redundant information. Some of these (for example, patterns of parallel lines) are already well known for their disturbing visual effects[1,2], particularly those due to eye-movements.

The main purpose of this communication, however, is to give a preliminary account of some particularly striking after-effects of such regular patterned stimulation, which seem to offer a promising new line of research into visual organization. One of the most interesting patterns so far constructed consists of 120 black radial stripes of width 1¼ degrees (Fig. 1), on sheets of matt white photographic paper, 30 cm. × 40 cm., viewed at 1 metre in daylight or normal room lighting. (Neither distance nor illumination is critical.) After an exposure of, say, 10 sec. this 'ray' pattern produces for a few seconds an immediate after-impression of wavy lines moving in circular orbits at right angles to the stimulus lines. It is proposed to call this the 'complementary pattern'. For most observers its initial direction of rotation appears to be constant. Out of a series of 110 subjects, 83 reported it as clockwise, 27 anti-clockwise. A few in each group saw the direction reverse spontaneously. 7 out of 83 of the 'clockwise' group and 5 out of 27 of the 'anti-clockwise' group were left-handed. There is thus no simple correlation with handedness, though the evidence suggests that left-right dominance may be one relevant factor. The direction may be induced to reverse by fixating a point to left or right of the centre of the stimulus pattern.

If part of the stimulus pattern is covered (for example, by a sheet of paper obscuring one half) during inspection, the corresponding portion of the complementary pattern is missing, but the portion which is visible is unchanged.

A second pattern made up of concentric black circles on a white background (Fig. 2) was designed as a dual of the 'ray' pattern. As might be expected, this 'target' pattern gives a complementary pattern dual to the first, rather like the petals of a chrysanthemum. Wavy lines stream radially from or to the centre, but the image does not normally appear to rotate. Here again it has been found unnecessary that the stimulus pattern should be complete, a

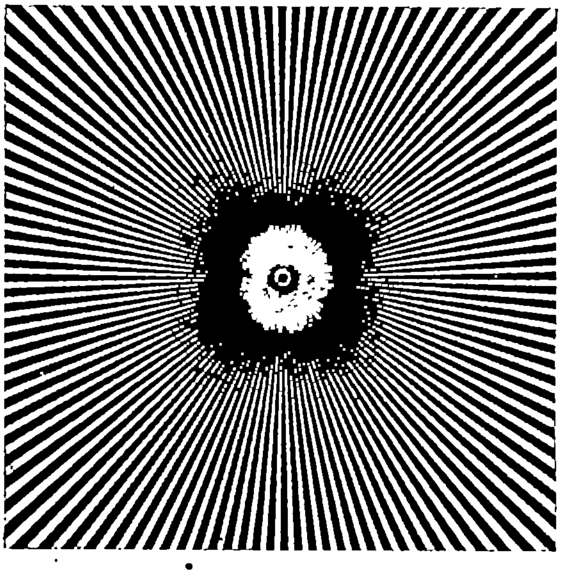

Fig. 1

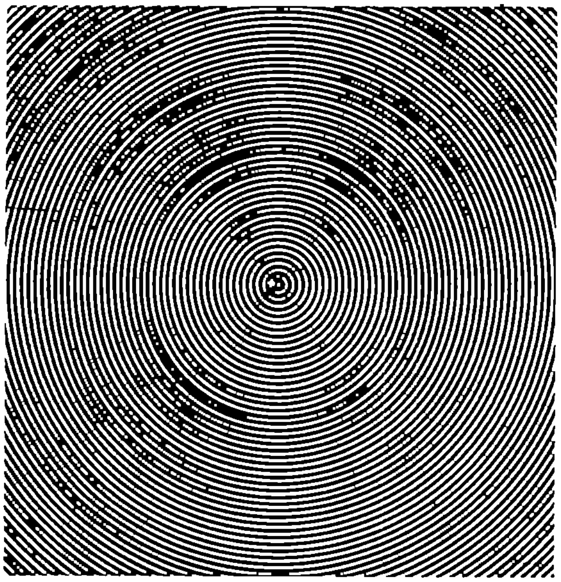

Fig 2

portion of the stimulus figure giving rise to a corresponding portion of the 'chrysanthemum' image.

These effects are more striking after binocular than after monocular stimulation. During prolonged monocular stimulation the complementary image may often be seen in apparent rivalry with the stimulus pattern, subjectively rather as if it were being presented to the occluded eye on a black background. This suggests that the activity it represents is not an 'off-response' but some kind of co-operative oscillation induced in the visual network by the regularity of the stimulus. This view is strengthened by four further facts: (*a*) Small blank areas introduced into such stimulus patterns appear under suitable conditions to be traversed continually by rapidly moving shadows. The phenomenon is well seen in patterns of parallel black bars arranged in columns side by side (Fig. 3), where the vertical channels between the columns of bars appear to show what most observers call a 'trickling' motion, as if water were running rapidly up or down each channel. (It was a chance observation of this on slotted B.B.C. studio wall-board in 1955 which first led me to experiment with patterns of parallel lines, and I am indebted to Mr. C. L. S. Gilford, of the Corporation, for assistance in making measurements on the original material.) The effect is more marked if the bars have square-cut ends than if they are rounded off. The complementary after-image of a parallel-bar pattern of this kind consists of wavy lines moving perpendicular to the bars, that is, in the direction of the channels between the columns of bars. It seems most likely, therefore, that the same activity is responsible for the 'trickling' seen during exposure of the pattern. (*b*) A randomly printed pattern of dots, viewed through a transparency of Figs. 1 or 2, takes on a static structure similar to that of the complementary image. Relative motion of the two patterns causes an interesting 'shearing' of this structure which is being investigated. (*c*) A spatio-temporally random pattern of visual 'noise' on a cathode-ray tube screen, viewed through such transparencies, evokes a vivid and continuous impression of the complementary image in motion. This discovery offers a simple technique for the future study of these images. (*d*) In stroboscopic light at rates of a few flashes per second, somewhat simplified complementary patterns of the same family may be observed superimposed on the stimulus pattern, usually outlined in a blue or green colour of remarkably high saturation.

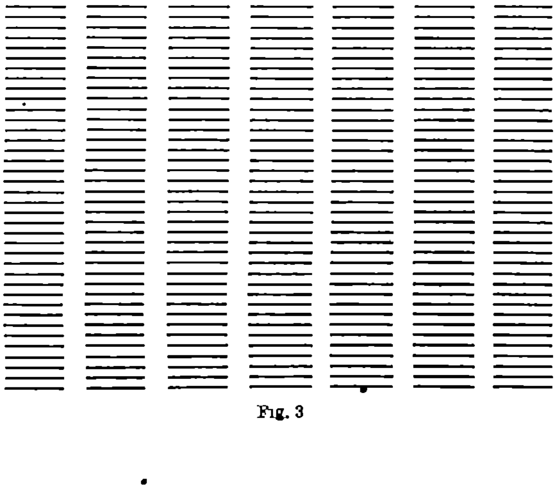

Fig. 3

The theoretical implications of these results are as yet far from clear, but it is suggested that there may be a significant connexion between the new phenomena and the well-known static figural distortions produced by similar patterns. In both cases, the universal rule is that the system tends to favour the direction at right angles to the regular contours, suggesting a theoretical model of form-perception in which directions at right angles are treated by the system as competitive. These phenomena could then be considered as evidence of what might be called 'directional satiation' in the appropriate network, together with co-operative oscillation (a kind of generalized standing-wave pattern) in response to the informational redundancy.

It will obviously be of great interest to localize these complementary responses. The evidence from monocular stimulation mentioned above suggests (though far from conclusively) that they are less likely to be of retinal than of central origin. On the other hand, it has been found that if Fig. 2 is presented to a subject satiated for rotation by viewing a turntable, the well-known rotational after-effect is superimposed on the 'chrysanthemum' after-image, which now appears to rotate in the opposite direction to the turntable. In preliminary experiments with a subject suffering from damage to the brain (to be reported elsewhere) a lesion due to a cerebral embolism, resulting in a wedge-defect in one quadrant, was found to suppress the complementary after-image of Fig. 1 over the whole of the damaged half-field, whereas that of Fig. 2 (the 'chrysanthemum') was suppressed only in the area of the scotoma, which became observable to the subject as a blank patch on the complementary image. After rotation satiation, the 'chrysanthemum' was reported to rotate past the blank patch. It seems, then, that the source of the oscillatory after-images lies on the retinal side of whatever system is modified by viewing the turntable. It is hoped that further experiments with subjects with brain damage may help with the problem of localization.

The assistance of Mr. W. R. Pritchard in constructing Figs. 1 and 2 is gratefully acknowledged.

PROTOPLASTS OF *E. COLI* AS SOURCES AND ACCEPTORS OF DEOXYPENTOSE NUCLEIC ACID: REHABILITATION OF A DEFICIENT MUTANT

By PROF. ERWIN CHARGAFF, HERBERT M. SCHULMAN and DR. HERMAN S. SHAPIRO

Cell Chemistry Laboratory, Department of Biochemistry, College of Physicians and Surgeons, Columbia University, New York

THE complete isolation of intact deoxypentose nucleic acid from *Escherichia coli* is not easy; and although deoxypentose nucleic acid preparations from this micro-organism have been described[1–3], and in a few cases fully analysed[1,2], it is not impossible that the unsatisfactory quality of many of these specimens is one of the reasons for the scarcity of information on bacterial transformation in this genus[4–6]. It seemed to us that experimentation would be facilitated if the organisms—donors as well as recipients of the biologically active material—were deprived of their cell walls. In the past few years great advances have been made in our understanding of protoplasts, forms of organized and, in some circumstances, viable bacterial protoplasm, remaining after the removal of the wall[7].

We have, consequently, explored the use of protoplasts of *E. coli*[8–10]. In the experiments reported here the penicillin method of Lederberg[8] was employed. The strains used, for which we are grateful to Prof. B. D. Davis, of New York University, were the wild-type *E. coli* strain *W* and the lysine-requiring mutant 26–26 derived from it. The latter is regarded as being blocked between α,ε-diaminopimelic acid and lysine[11].

We shall first describe the isolation and the composition of deoxypentose nucleic acid prepared from the protoplasts of the wild-type strain and then present the evidence of the restoration, by this deoxypentose nucleic acid, of the protoplasts of the lysine auxotroph to prototrophic conditions no longer requiring a supply of lysine—a form of bacterial transformation to which we should like to refer as 'redintegration'.

Crude nucleic acid from E. coli *protoplasts*. For each preparation, 300 ml. of a culture of *E. coli* strain *W*—grown overnight at 37° in 'Difco Penassay' broth—was added to 1,000 ml. of the same medium containing 20 per cent sucrose, 0·2 per cent magnesium sulphate and 1,000 units per ml. of penicillin[8]. After three hours on a rotating shaker at room temperature, only protoplasts could be seen. These were collected in the cold by centrifugation at 5,000*g* for 20 min. and washed twice with 80 ml. and 40 ml. of 20 per cent sucrose solution. The washed protoplasts first were extracted twice with 30 ml. portions of cold 0·1 *M* sodium chloride solution (0·05 *M* with respect to sodium citrate), each treatment being followed by centrifugation in the cold at 23,000*g* for 20 min., and the sediment then was rapidly stirred for 15 min. with 25 ml. of cold 10 per cent sodium chloride solution. The viscous suspension was centrifuged (23,000*g*, 20 min.) and the sediment extracted once more for several hours. The slightly opalescent supernatant fluids were injected into 2 volumes of 95 per cent ethanol. The fibrous precipitate was collected and the cycles of extraction with 10 per cent sodium chloride solution, centrifugation and precipitation with alcohol were repeated. Most of the fibres could be dissolved in 10 ml. of 0·15 *M* sodium chloride solution. The solution was clarified (23,000*g*, 40 min.) and adjusted to a molarity of 2·6 by the addition of solid sodium chloride; the crude nucleic acid was precipitated with 2 volumes of ethanol and stored in the cold in 70 per cent ethanol.

This is the stage at which the preparations were used in the subsequent biological experiments. They were isolated with the avoidance of any but the mildest procedures for the removal of protein and ribonucleic acid that are successful in the preparation of deoxypentose nucleic acid from calf thymus[12]; but they were not pure and contained varying amounts of ribonucleic acid and protein. For example, 300 ml. of initial bacterial culture yielded, in one case, 6·3 mgm. deoxypentose nucleic acid, 2·6 mgm. ribonucleic acid, 2·2 mgm. protein; in another preparation, the figures were: 4·1 mgm. deoxypentose nucleic acid, 2·4 mgm. ribonucleic acid, 2·2 mgm. protein.

Composition of deoxypentose nucleic acid from E. coli *protoplasts*. It appeared of interest to determine the purine and pyrimidine composition of the protoplast deoxypentose nucleic acid. The methods of purification are mentioned in Table 1, which gives the average analytical figures for four preparations. The analyses were performed by the usual methods[13]. One of the specimens (Prep. 2) that had not been in contact with alkali had $\epsilon(P) = 6{,}900$ at 260 mμ and *p*H 7[14]. In their composition, the deoxypentose nucleic acid preparations under study here are remarkably similar to those from other *E. coli* strains described previously[1,2,14], also as regards the unusual, nearly equimolar distribution of the nitrogenous constituents. This is the fifth strain of *E. coli* for which this holds true.

The 'redintegration' phenomenon. One series of experiments is described here, the results of which are shown in Table 2. (1) The lysine-requiring mutant 26–26 of *E. coli* was grown overnight in 'Penassay' broth at 37°. For the production of protoplasts, 3-ml. portions of this culture were added to 10 ml. of the penicillin-sucrose medium[8] mentioned at the beginning of this communication, with the following additions. Exp. 1, none; Exp. 2, 1 per cent human serum albumin; Exp. 3, a preparation of the crude nucleic acid from wild-type *E. coli*, strain *W* described before, in an amount corresponding to approximately 0·25 mgm. of nucleic acid phosphorus; Exp. 4, the same quantity of the nucleic acid and 1 per cent albumin. After agitation at room temperature for 2½ hr., the protoplasts were collected by centrifugation in the cold and washed once with 20 ml. of cold 20 per cent sucrose solution which, in Exps. 2 and 4, was supplemented with 1 per cent albumin.

(2) Each protoplast preparation was suspended in 10 ml. of 20 per cent sucrose solution containing the minimal medium (7 gm. dipotassium hydrogen phosphate, 3 gm. potassium dihydrogen phosphate, 0·5 gm. sodium citrate, 1 gm. ammonium sulphate, 0·1 gm. magnesium sulphate, 5 gm. glucose per litre). Nucleic acid also was present in Exps. 3 and 4, and albumin in Exps. 2 and 4, in the concentrations mentioned above. The suspensions were shaken at 35° for 30 min.

(3) Each mixture was then added to 10 ml. of double-strength 'Penassay' in 20 per cent sucrose solution, again supplemented with the same quantities of nucleic acid (Exp. 3), albumin (Exp. 2) or both (Exp. 4). The mixtures were incubated with shaking at 35° for 2 hr., by which time the spherical protoplasts had reverted to rods, and then left shaking at room temperature for 14 hr.

(4) 10-ml. portions of each culture were centrifuged, the cell sediments were washed three times with 5 ml. portions of 0·15 *M* sodium chloride solution and finally suspended in 2 ml. of physiological saline. Proper dilutions then were spread on agar plates containing the minimal medium without or with L-lysine (50 μgm. per ml.). The results are summarized in Table 2.

When cultures, in 'Penassay' broth, of the mutant 26–26 that had not passed through the protoplast phase or been treated otherwise were harvested and dilutions of the washed cells were spread on agar plates, the number of prototrophs was 0·01 per 1,000 cells. It is not impossible that the passage through the protoplast stage in itself somewhat enhances the frequency of reverse mutation; but this remains to be developed in detail. It will be gathered from Table 2 that the treatment of the lysine-requiring protoplasts with nucleic acid from the wild-type strain produced an approximately twenty-fold increase in prototrophic cells in the presence of serum albumin (Exps. 2 and 4), a five-fold increase in its absence (Exps. 1 and 3). The protective effect of serum albumin on protoplasts of *E. coli* has been pointed out before[8].

The events controlling this restoration are far from clear. We have thus far studied the action of ten preparations of crude nucleic acid on the protoplasts of mutant 26–26 in twelve separate experiments, of which only six have given positive results. Most of the failures were, however, recorded before the use of serum albumin. We believe the principal cause of these failures to be the excessive breakage of protoplasts and the release of deoxyribonuclease; in successful experiments the suspension of protoplasts in solutions containing nucleic acid (stage 2 of the procedure described above) retained a high viscosity for a considerable period. It may also be advisable to ascertain the absence of enzymes capable of depolymerizing deoxypentose nucleic acid from the preparation of human serum albumin employed.

Table 1. COMPOSITION OF SODIUM DEOXYPENTOSE NUCLEATE PREPARED FROM PROTOPLASTS OF *E. coli*, STRAIN *W*

	Preparations 1, 2*	Preparations 3, 4†

$\frac{\text{Adenine + thymine}}{\text{Guanine + cytosine}}$	0·94	0·93

* These preparations were completely freed of ribonucleic acid by the adsorption of the latter on activated charcoal (Zamenhof and Chargaff, *Nature*, 168, 604 (1951)). The figures represent averages of the analytical results given by both specimens. They have been adjusted to a 100 per cent recovery. The actual recovery was 93·2 per cent.

† Ribonucleic acid was removed from these preparations by treatment with 0·3 *M* sodium hydroxide (30°, 18 hr.) and subsequent dialysis. The figures are corrected averages, as explained in the preceding footnote. The actual recovery was 86·7 per cent.

Table 2. TREATMENT OF PROTOPLASTS OF LYSINE-REQUIRING MUTANT 26–26 WITH NUCLEIC ACID FROM PROTOPLASTS OF WILD-TYPE *E. coli*, STRAIN *W**

Exp.	Addition		No. of viable cells in original 2 ml. portion		No. of prototrophic cells per 1,000 cells
	DNA	Albumin	With lysine	Without lysine	
1	–	–	$2 \cdot 2 \times 10^9$	$8 \cdot 0 \times 10^4$	0·03
2	–	+	$4 \cdot 0 \times 10^9$	$1 \cdot 3 \times 10^5$	0·03
3	+	–	$2 \cdot 0 \times 10^9$	$4 \cdot 1 \times 10^5$	0·2
4	+	+	$4 \cdot 3 \times 10^9$	$2 \cdot 4 \times 10^6$	0·6

* The procedures for the treatment of the protoplasts are described in the text. For the viability counts, portions of each dilution were spread on three plates (48 hr., 37°). The figures are averages of closely agreeing triplicate determinations.

It would seem that the phenomenon observed by us belongs to the general category of bacterial transformation. We should, however, hesitate to affirm this before more rigorous proof has been obtained that a deoxypentose nucleic acid is the agent responsible. The permanent abolition, by a substance present in the wild-type, of the metabolic defect of an auxotroph and the restoration of the deficient cell to prototrophic requirements are, perhaps, best described as 'redintegration'. It will be of interest to see whether, in the mutant studied here, this event is accompanied by the appearance of diaminopimelic acid decarboxylase[15]. We are continuing the study of several aspects of the redintegration phenomenon and hope to give a fuller account in due course.

We thank Prof. J. Lederberg, of the University of Wisconsin, for acquainting us with his procedure for the preparation of protoplasts before its publication; Prof. B. D. Davis, of New York University, for the gift of bacterial cultures; and Prof. F. J. Ryan, of Columbia University, for helpful discussions. The work was supported by research grants from the United States Public Health Service, the American Cancer Society and the National Science Foundation.

An Attempt to cross the Domestic Rabbit (*Oryctolagus cuniculus*) and Hare (*Lepus europæus*)

PREVIOUS attempts[1] to obtain young from domestic rabbits by insemination with epididymal spermatozoa from hares (*Lepus timidus ainu* or *Lepus europæus*) have proved unsuccessful. The possibility, however, that fertilization and a limited amount of embryonic development may have occurred has not so far been investigated. Recently[2], it was found that in rabbits inseminated with epididymal spermatozoa from the eastern cottontail rabbit (*Sylvilagus floridanus*), 37 per cent of the eggs were fertilized but degeneration occurred at all stages before or at blastulation. The experiment described here was undertaken to determine whether fertilization occurred in rabbits inseminated with hare spermatozoa and, if so, at what stage development ceased.

During May and June, four male hares (Nos. 1–4) were shot locally and returned to the laboratory within one hour of death. Spermatozoa were obtained from the epididymides and suspended in Krebs's Ringer bicarbonate solution at 37° C., which induced a high degree of motility. Each female rabbit was inseminated with 1 ml. of sperm suspension. The ten adult female rabbits, *A–I*, used for this experiment were caged separately and not mated for a period of at least 30 days prior to the experiment. They were given an intravenous injection of 1 mgm. equivalent of pituitary lutealizing hormone (PLH, Armour Laboratories) to induce ovulation. Immediately afterwards, rabbits *A* and *B* were inseminated with 110 million spermatozoa (from hare No. 1), rabbits *C–H* received 160 million spermatozoa (mixed sample from hare Nos. 2 and 3) and does *I* and *J* received 692 million spermatozoa (from hare No. 4). One Fallopian tube was removed from rabbits *A* and *B* at 31 and 54 hr. after insemination. These rabbits were allowed to recover and were then autopsied at 122 and 145 hr. after insemination. The remaining eight rabbits were killed at intervals varying from 29 to 124 hr. after insemination. The technique of egg recovery has already been described[3]. The recovered eggs were examined microscopically to determine their general condition, stage of development and numbers of spermatozoa present.

The mean total number of ovulations per rabbit was 10·6 ± 0·6 (standard error of mean), range 8–15. Details of the number and condition of eggs recovered are given in Table 1. In rabbits examined at, or later than, 73 hr. after insemination, forty-nine eggs (equivalent to 100 per cent of the ovulations) were recovered from the Fallopian tubes; two of these eggs were uncleaved, four showed retarded development, whereas the remaining forty-three had reached a stage of development appropriate to their age. A total of thirty-eight eggs (66·7 per cent of the ovulations) were recovered from the uteri of the rabbits killed at 122–145 hr. after insemination. Although all thirty-eight eggs had undergone cleavage, no egg had developed beyond the early blastocyst stage, which is normally observed 84 hr. after mating; there were five early blastocysts and thirty-three late morulæ in which development had ceased between 60 and 70 hr. after insemination. Small numbers of spermatozoa, varying from one to six per egg, were observed in the perivitelline space, zona pellucida and mucin; there appeared to be no relationship between the number present and the number used for insemination. The proportion of eggs 'fertilized', as determined by cleavage, was 97·7 per cent, which is not significantly different from the figure obtained from normally mated rabbits[4].

Table 1. EGG DEVELOPMENT FOLLOWING INSEMINATION OF RABBITS WITH EPIDIDYMAL SPERM OF HARES

Rabbit	Interval between insemination and egg recovery (hr.)	No. of ovulations	No. of eggs recovered and stage of egg development
A	31*	4	2, 1-cell ; 2, 2-cell
	145	4	1 early blastocyst
B	54*	4	3, 4-cell ; 1, 16-cell
	122	6	3 late morulæ ; 1 early blastocyst
C	29	10	10, 4-cell
D	67	11	11 late morulæ
E	122	15	9 late morulæ ; 1 early blastocyst
F	123	11	10 late morulæ
G	124	12	5 late morulæ ; 2 early blastocysts
H	124	9	6 late morulæ
I	49	10	4, 8-cell ; 3, 12-cell ; 3, 16-cell
J	73	10	1, 16-cell ; 9 late morulæ

* Tubalectomy performed

Three questions which these observations raise are: (1) Were the eggs fertilized? (2) Did parthenogenetic development occur? (3) Why did development fail at the late morula or early blastocyst stages? The presence of hare spermatozoa in the perivitelline space and zona pellucida of rabbit eggs suggests that they provided the stimulus for development. Since no egg reached the five-day blastocyst stage, no attempt was made to determine the chromosome number[5], and it is therefore not possible to state whether male hereditary material was transmitted to the eggs. For the time being, no explanation other than incompatibility can be advanced to account for the failure of the eggs to develop beyond the early blastocyst stage. Interspecific crosses are rarely possible, and this is often thought to be due to an immunological incompatibility, of a statistical nature, between combining groups on the surfaces of the heterologous eggs and spermatozoa[6]. These observations suggest that in certain cases this incompatibility may not exist, though the other barriers to successful interspecific crosses do.

I am grateful to Lord Rothschild and Dr. T. Mann for reading the manuscript and making valuable suggestions. My thanks are due to Mr. R. V. Short, and Mr. J. Engledow of Messrs. Chivers and Sons, Ltd., for providing the hares.

Absence of Wound Healing in Young Chick Embryos

During attempts to modify the development of feather tracts, Saunders had noted the fact that skin wounds in three-day chick embryos failed to heal[1]. This casual observation, which contrasted curiously with the numerous reports on smooth healing of embryonic transplants and the repair of older skin, seemed to hold a promising clue to the mechanisms of wound healing in general. We therefore undertook a more systematic study of the phenomenon, the first results of which are reported in the following.

Circular skin wounds were made on the dorsal side of the neck in chick embryos from five days of incubation age upward until hatching. The wounds measured in the younger embryos (5–9 days) about 0·1 mm. in diameter and 0·1 mm. in depth, and in the older ones (10–21 days) 1 mm. and 0·5 mm., respectively. After the operations, the segment of shell removed for access to the embryo was replaced by a glass window. The embryos were killed four to five days after the operation, fixed, sectioned, stained, and studied microscopically.

The normal healing of skin wounds is primarily a process of cell migration. The epidermal sheet moves with its free margin concentrically over the defect until the hole is closed by a thin layer of cells. Proliferation by mitotic division follows secondarily, gradually making up for the initial deficit of cells.

Wounds made in chick embryos older than twelve days and studied between the seventeenth and twenty-first days showed this same standard pattern of epidermal regeneration. However, embryos operated on at an early stage and studied prior to the twelfth day gave a radically different result. The epidermal sheet had not even started to move over the lesion, and its free margin was still at the site of the original wound edge. Mitotic activity near the margin was high, and the excess cell production had given rise to local thickenings and cysts. Despite this abundant growth along the border, the wound surface had remained raw, bounded only by the condensed outer layer of connective tissue cells. The earlier embryo thus is distinguished by the marked incapacity of its epidermis to spread over the wound surface, even though cell multiplication is stepped up much as in the older group that healed normally. An intermediate age-group, studied between the thirteenth and sixteenth days of incubation, showed signs of flattening of epidermal cells along the border and some contraction of the wound area, thus signalling presumably the initiation of the normal closure process. Fig. 1 summarizes the cases that survived the operation and could be properly evaluated.

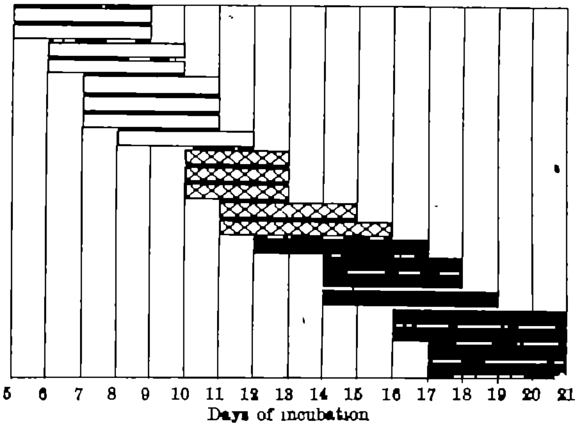

Fig. 1. Bars indicate period of observation between wounding and fixation in days after incubation. White bars, absence of wound healing; cross-hatched bars, incipient wound healing; black bars, complete wound healing

It can be seen that there is a rather abrupt change in the embryonic conditions conducive to wound healing about the twelfth day of incubation. Since, moreover, embryos prior to that critical period neatly dissociate the migratory component of wound healing (which is absent) from the proliferative component (which is present), this object lends itself singularly well for a more penetrating analysis of the fundamentals of wound healing. The crucial change about the twelfth day may be found in the mobility of the epidermal cells, or in the constitution of the wound substratum, or in systemic changes in the embryo, or in the nature of the extra-embryonic fluid, or in the tensional stresses, or other as yet unsuspected conditions. The location, shape and size of the lesion will likewise have to be taken into consideration. Experiments to pinpoint the effect are under way. One preliminary series has already led a step further in indicating that embryos operated on during the early non-reparative phase, but kept alive into advanced embryonic stages, later start to close their wounds, all just about the critical age when closure was observed in the older series. This would mean that the initiation of migration cannot possibly be related to the wound stimulus as such. It would, of course, also account for the fact that early transplants kept into later stages no longer show skin gaps, the earlier existence of which one might expect from the results reported above.

Autoradiographic Detection of Sulphone in the Affected Tissues of Leprosy Patients

In two previous communications[1,2], the relative concentrations of diamino-diphenyl sulphone in body fluids and affected and healthy tissues of leprosy patients were compared. It was shown that the drug was preferentially concentrated in the affected tissues. In these studies the assay of radioactive drug in any tissue was made by counting macerated samples with the help of a Geiger–Müller counter.

Autoradiographic studies have now been made to determine the exact sites of localizations of the drug in the affected tissues. Positive autoradiographs of tissue sections are reproduced here.

Diamino-diphenyl sulphone labelled with sulphur-35 (supplied by the Atomic Energy Research Establishment, England) was administered to patients as a single oral dose of 4 μc./kgm. body-weight. The initial specific activity of the drug was 1·0 μc./mgm. 6–18 hr. after administration of the drug samples of tissues were obtained by biopsy. These were fixed

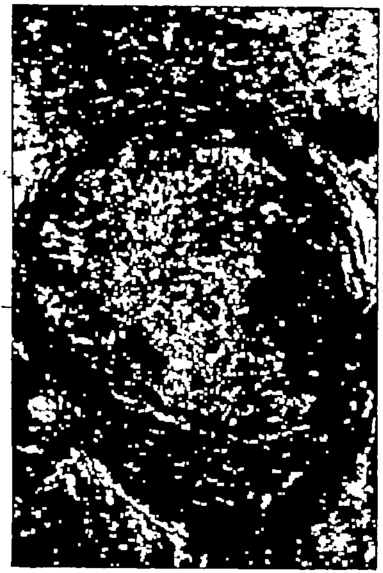

Fig. 1. Autoradiograph of the transverse section of a blood vessel. (× c. 1,330)

in neutral formalin and 5μ frozen sections were cut. Sections were then placed on glass slides, covered with Kodak autoradiographic stripping film and exposed for 180 days in dry light- and air-tight chambers at 4° C. Films were then developed in undiluted *D* 195 for 5 min. at 65° F. to keep the background as low as possible.

Fig. 1 is the autoradiograph of a transverse section of a blood vessel indicating the presence of the drug within it by the blackened photographic grains. Figs. 2 and 3 are autoradiographs of longitudinal and transverse sections of peripheral nerves. The density of the grains are more marked in places where the infiltrating cells are predominant. The space between adjacent fibrils is found to be almost free of the drug. Fig. 3 shows that the drug is more localized within the different cells of the nerve.

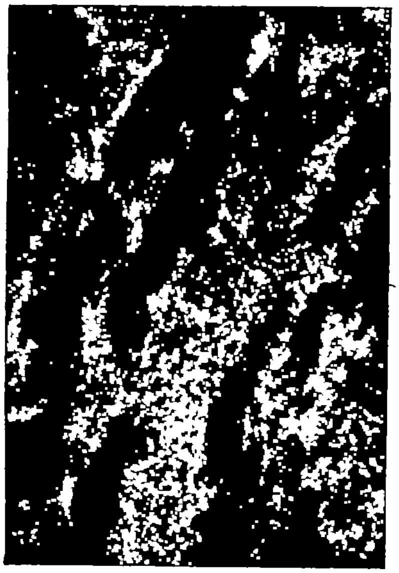

Fig. 2. Autoradiograph of the longitudinal section of a nerve. (× c. 1,330)

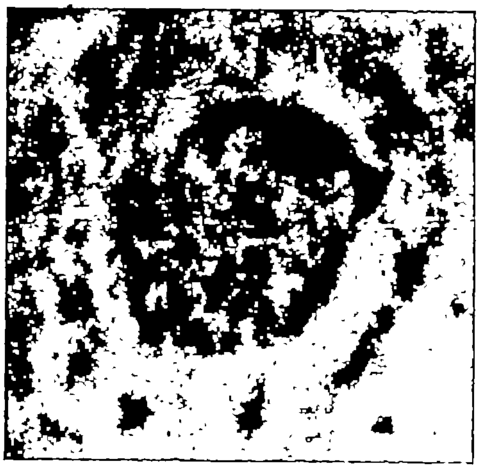

Fig. 3. Autoradiograph of the transverse section of a nerve. (× 2,000)

Effect of Hypoglycin *A* on the Alpha Cells of the Pancreas

Hypoglycin-*A*, which is isolated from the fruit of *Blighia sapida*, causes severe hypoglycæmia and depletion of liver glycogen[1,2]. Leppla and Holt[3] examined the hypothesis that glucagon depletion following pancreatic alpha-cell damage might be the cause of these metabolic changes. However, as they could not find any microscopical changes in the alpha cells after hypoglycin *A* administration, they were unable to support this hypothesis.

In order to re-examine the possibility, the following study was carried out. Albino rats and guinea pigs were injected intraperitoneally with a single lethal dose (150–300 mgm./kgm.) of hypoglycin *A*. When death was obviously imminent the animal was killed and the pancreas was excised for histological examination. In order to check the activity of the hypoglycin *A*, blood glucose and liver glycogen levels were also determined; both of which were found to be invariably low.

Serial sections of pancreas were stained with eosin and hæmatoxylin, Gomori's chrome-alum–hæmatoxylin and phloxine[4], and Gomori's aldehyde fuchsin and phloxine[5]. A decrease of alpha granules and/or number of alpha cells in the islets was observed. Occasionally, there was a complete absence of the alpha cell (Fig. 1). The beta cells and the acinar cells appeared normal.

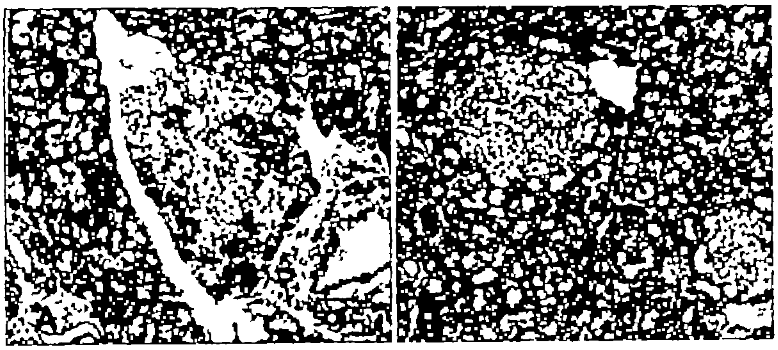

Fig. 1. Pancreatic islet of guinea pigs; Gomori's chrome-alum-hæmatoxylin and phloxin stain. *A*, Normal islet; *B*, pancreatic islets of animals which died 16 hr. after intraperitoneal injection of 200 mgm./kgm. of hypoglycin-*A*

Although the pathological changes in the alpha cells induced in these experiments by hypoglycin *A* may lead to a decrease of glucagon production, and thus contribute to the depletion of the liver glycogen and the fall of blood glucose, these histological changes are not likely to be the sole factor involved, since cobalt chloride, which produces far more extensive and destructive damage to the alpha cells, causes different metabolic changes.

Urinary Œstrogen Excretion by the Bull

According to Leach *et al.*[1], several observations indicate that in the human male the testis accounts for 80 per cent or more of the urinary œstrogens. Maddock and Nelson[2] claim that œstrogen excretion is a more reliable and sensitive indicator of Leydig cell function than is 17-ketosteroid excretion. These views are supported by Leach *et al.*[1]. Conti *et al.*[3] found increased œstrogen excretion in six patients with hypogonadism and hyperplasia of the Leydig cells. The urinary œstrogens were doubled during chorionic gonadotropin administration. The results of Dux *et al.*[4] support the findings of Maddock and Nelson[2] that secretion of œstrogens by the mature testis is a highly specific reaction to chorionic gonadotropin. The authors claim intravenous drop infusion of chorionic gonadotropin to be of clinical value in evaluation of the endocrine functions of the testis.

In the bovine species male sterility is a problem and the need for new diagnostic methods is obvious. So far as I am aware, no attempt has as yet been made towards quantitative analysis of urinary œstrogens in the bull. In this communication results are presented which indicate that a modification of the Brown method for human urinary œstrogens[5] may be applied to determine urinary œstrogens in the bull, and that the substance isolated in the œstradiol-fraction increases significantly in response to the administration of chorionic gonadotropin.

Using specially constructed equipment, urine was collected for 24-hr. periods from a bull showing normal sexual activity.

1/10 of each 24-hr. urine was diluted to a final volume of 1,000 ml. with distilled water, and duplicates of 500 ml. each were hydrolysed for 1 hr. at 100° C., using 6 vol. per cent hydrochloric acid.

Extraction and purification were performed according to Brown[5], with some minor modifications[6]. The œstriol fraction was not analysed, as earlier experiments indicated an unspecific reaction to the Kober reagent for this fraction. The Kober reagents were made according to Bauld[7]. All readings were made in a Beckman Model *DU* spectrophotometer at the following wave-lengths: œstrone, 480, 516 and 552 mμ; œstradiol, 480, 518, 556 mμ.

The chorionic gonadotropin used was 'Physex' (Leo, Copenhagen). It was given as intramuscular injections in the first hour of the 24-hr. collecting periods on days 5, 6, 7 and 8 of the experiment. On day 8 it was given in the first and eleventh hour of the collecting period. The results are given in Table 1. No increase can be observed in the œstrone fraction during the chorionic gonadotropin administration. The amounts registered are so small as to render the determinations uncertain. However, in the œstradiol fraction a marked increase is observed. On the second day after the last injection of chorionic gonadotropin the values for this fraction fall to the initial level. The Kober chromogen in the œstradiol fraction is completely destroyed when the urine is submitted to boiling for 2 hr. using 15 vol. per cent of hydrochloric acid. Additional information from work on urinary œstrogens in pregnant and non-pregnant cows (Velle, W., unpublished work) indicate that the substances measured represent true œstrogens.

The results represent, so far as I am aware, for the first time a chemically determined increase in urinary œstrogen excretion following chorionic gonadotropin administration, and therefore give support to earlier observations in the human male, based on bioassay. They also suggest a possible new method for diagnosing certain forms of sterility in bulls.

Table 1. Increase in Urinary Œstrogen Excretion in a Bull, following Chorionic Gonadotropin Administration

Influence of Starvation and Glucose Load on the Activity of Liver Phosphorylase in Normal and Adrenalectomized Rats

RECENTLY, it has been shown by Sutherland *et al.*[1,2] that liver phosphorylase is acted on by two different enzymes. They found that the inactivation of liver phosphorylase was caused by an enzyme which appeared to be a phosphatase able to split off phosphate from active liver phosphorylase and thus render it inactive. Furthermore, they were able to demonstrate the existence of another enzyme able to reactivate inactive phosphorylase. In an earlier work, Sutherland and Cori[3] showed that epinephrine and glucagon play an essential part in the activation of liver phosphorylase, and evidence has since been established for the assumption that epinephrine and glucagon are reacting in some way or other with the reactivating enzyme. The complete mechanism has not yet been worked out, although a recent paper published by Rall, Sutherland and Berthet[4] has elicited the problem further.

The present experiments were carried out to study the phosphorylase activity in livers from different groups of rats. Phosphorylase activity was measured by the phosphate release method. Diluted homogenates were incubated at 37° with a reaction mixture of the same composition as that used by Sutherland *et al.*[5]. Besides glucose-1-phosphate the reaction mixture contained muscle adenylic acid, glycogen and sodium fluoride. The reaction mixture was adjusted to *p*H 6·1 with hydrochloric acid. Activity was expressed as the amount of phosphate released in 20 min. per mgm. nitrogen in the homogenate sample transferred to the reaction mixture. Only male rats were used, their weights ranging between 150 and 250 gm. All rats were anæsthetized with nembutal. The adrenalectomized rats were maintained on sodium chloride in the drinking water, and they were not used before three weeks after the operation. The liver samples were homogenized in physiological saline exactly two minutes after removal. Precisely four minutes after liver biopsy, the enzyme reaction was started by the addition of diluted homogenate to the reaction mixture. With intervals of five minutes, another four samples were taken from the diluted homogenate for activity determinations. By this procedure it was possible to measure the rate of inactivation in the diluted homogenate, which was placed in a water bath at 25°. The inactivation was in all cases linear for the first ten minutes. The decrease of activity during the first ten minutes in percentage of the initial value was taken as a measure of the inactivation.

It was found that fasted rats had lower phosphorylase activity than non-starved animals. A decrease in the rate of inactivation parallel to the decrease in phosphorylase activity was also noted (Table 1).

Table 1

	Group No.	No. of animals	Activity of phosphorylase (γ P/mgm. N)	Rate of inactivation (per cent)
Normal, non-fasted	1	15	636·1 (61·7)	50·7 (6·7)
Normal, fasted 20 hr.	7	12	504·9 (107·2)	34·7 (10·7)
Normal, fasted 48 hr.	8	9	378·5 (93·5)	25·3 (9·6)

Standard deviation is given in brackets

It is already known that the phosphorylase activity in livers from adrenalectomized rats is decreased[6]. This is confirmed in the present study. Furthermore, a pronounced fall of activity in the fasted adrenalectomized animals as compared with the non-fasted ones was demonstrated. Also in the case of adrenalectomized rats it was found that the rate of inactivation was decreased in the group of fasted animals with decreased phosphorylase activity (Table 2).

Table 2

	Group No.	No. of animals	Activity of phosphorylase (γ P/mgm. N)	Rate of inactivation (per cent)
Adrenalectomized, non-fasted	10	12	477·2 (87·8)	39·3 (5·6)
Adrenalectomized, fasted 20 hr.	11	8	310·2 (28·8)	15·5 (3·7)

Standard deviation is given in brackets

Sutherland *et al.*[2] mention that the process of inactivation–reactivation is very fast and assume that all phosphorylase in the liver could be reactivated in a few minutes. It seemed of interest to study the possible influence of induced hyperglycæmia on the activity of liver phosphorylase in the intact animal and therefore some short-time experiments on animals loaded with glucose were performed. The glucose was administered either per os in a stomach tube or intravenously in a femoral vein. Liver biopsy was carried out 20–30 min. after the glucose had been administered. The intravenous-treated rats had blood-sugar values about 300 mgm. per cent and the peroral-treated animals had blood-sugar values about 200 mgm. per cent when liver biopsy was done. The results of the experiments are given in Table 3.

It was noted that phosphorylase activity was decreased when the animals were treated with glucose. The decrease in the case of group 2 is not significant. The differences in the remaining four experiments are statistically significant as compared with the untreated groups. Adrenalectomized rats were the most sensitive, and fasted animals were more sensitive than non-fasted ones. The rate of inactivation was found to increase in the glucose-treated groups 9 and 20, where a rise in mean values of about 50 per cent is registered.

It is not possible to draw definite conclusions from the experiments mentioned; but the results seem

Table 3

	Group No.	No. of animals	Glucose administration	Activity of phosphorylase (γ P/mgm. N)	Rate of inactivation (per cent)
Normal, non-fasted	1	15	—	636·1 (61·7)	50·7 (6·7)
Normal, non-fasted	2	7	oral	609·7 (55·5)	52·7 (8·9)
Normal, non-fasted	17	10	intravenous	546·7 (87·7)	54·7 (10·8)
Normal, fasted 20 hr.	7	12	—	504·9 (107·2)	34·7 (10·7)
Normal, fasted 20 hr.	9	8	oral	451·5 (42·2)	51·8 (8·2)
Normal, fasted 20 hr.	20	11	intravenous	429·5 (56·3)	49·4 (8·9)
Adrenalectomized, non-fasted	10	12	—	477·2 (87·8)	39·3 (5·6)
Adrenalectomized, non-fasted	22	8	intravenous	300·1 (70·1)	43·5 (9·4)

Standard deviation is given in brackets

to indicate that the inactivation–reactivation mechanism of liver phosphorylase is of great importance in the regulation of the glucose uptake and glucose output of the liver. A more detailed report and discussion will appear later in Reports of the Steno Memorial Hospital and the Nordisk Insulinlaboratorium.

Development of Chemical Thermoregulation in Piglets

HUSBANDRY experience and experimental work indicate that in the first two weeks it is generally not possible to rear piglets successfully in a cold or draughty environment.

These facts prove that there is a non-effective thermoregulation mechanism in piglets. During repeated studies of development of this mechanism in piglets, body temperature is usually used as an indicator. This criterion for solving this question is far from satisfactory and, because it cannot uncover the mechanism of thermoregulation, we decided to study the development of consumption of oxygen in piglets at varied ambient temperatures.

Large White bred piglets of both sexes, reared under infra-red lamps at a temperature of 15–18° C., were used for experiments. The procedure was as follows: piglets were kept singly for 30 min. at a temperature of 23 ± 1° C., then at 3 ± 1° C., and again at a temperature of 23 ± 1° C. At the end of each of these periods, the rectal temperature of the piglets was read. In the first two periods the oxygen consumption was measured by a Krogh respirometer (Tables 1, 2 and 3).

The finding of decreased consumption of oxygen during postnatal development confirms findings which were made earlier[1,2].

The fact that even on the sixth day the piglets do not react to decreased environmental temperature through increased metabolism proves that their thermoregulation system is immature. Further proof of this fact is that the temperature of the body greatly decreases in cold, and after a 30-min. stay in warmth it has not yet returned completely to its initial value. Also, the vasomotor reaction based on contraction of skin vessels in this period fails and after five minutes in the cold the piglets are cyanotic. Pilomotor reaction—bristling—and shivering of muscles appear in this period. Both mechanisms are clearly insufficient. Not until the ninth day of life is there improvement of homeothermism. Around the twentieth day the piglets attain the further degree of maturity of thermoregulation.

Attention has frequently been directed to the relation between body-weight of piglets and thermoregulation. To make clear this relation we separated piglets, the oxygen consumption of which was measured between the sixth and tenth day, into two groups. Into the first group we put those individuals which reacted to cold environment by increased oxygen consumption, and into the second group, those which did not have this reaction. Weight differences between groups were not significant, even though piglets which had the same oxygen consumption in cold and warm environments were on the average lighter. The difference in oxygen consumption of the 6-day old piglets and the 9-day old piglets was statistically significant. Therefore, it is necessary

Table 1. CONSUMPTION OF OXYGEN IN PIGLETS IN ENVIRONMENTS OF VARIED TEMPERATURES ACCORDING TO AGE

Age of piglets (days)	Number of measurements	Consumption of O_2 in ml./kgm./min. in environmental temperature of 23 ± 1° C.	3 ± 1° C.	*P*
3	7	20·2 ± 8·1	15·9 ± 5·1	> 0·1
4–5	6	19·2 ± 8·3	17·4 ± 7·9	> 0·6
6	7	16·4 ± 3·6	16·4 ± 2·9	1·0
9–10	14	14·9 ± 2·7	23·3 ± 4·6	< 0·01
12–13	18	17·5 ± 3·5	25·7 ± 3·4	< 0·01
16–17	12	15·7 ± 3·6	20·9 ± 4·9	< 0·02
20	14	17·3 ± 6·2	26·1 ± 8·1	< 0·01
23	7	11·2 ± 3·3	30·3 ± 6·3	< 0·01
27	7	19·0 ± 5·1	33·4 ± 4·3	< 0·01

Table 2. DECREASING BODY TEMPERATURE OF PIGLETS IN ENVIRONMENT OF VARIED TEMPERATURES

Age of piglets (days)	Number of measurements	Decrease in body temperature in °C.	
		in 30 min. at temperature of 3 ± 1° C.	in further 30 min. at temperature 23 ± 1° C.
3	7	1·8 ± 0·14	0·8 ± 0·17
6	14	1·8 ± 0·25	0·8 ± 0·18
9–10	14	1·2 ± 0·19	0·6 ± 0·11
12–13	13	0·8 ± 0·16	0·5 ± 0·03
16–17	15	0·8 ± 0·15	0·6 ± 0·11
20	13	0·4 ± 0·02	0·3 ± 0·02
23	7	0·4 ± 0·13	0·1 ± 0·12
27	7	0·5 ± 0·02	0·2 ± 0·02

Table 3. CONSUMPTION OF OXYGEN IN PIGLETS BETWEEN SIXTH AND TENTH DAY OF LIFE AND ITS RELATION TO BODY-WEIGHT IN ENVIRONMENT OF VARIOUS TEMPERATURES

Number of measurements	Body-weight of piglets (kgm.)	Consumption of O_2 in ml./kgm./min. in environmental temperature of		*P*
		23 ± 1° C.	3 ± 1° C.	
12	2·59 ± 0·709	17·3 ± 3·2	17·3 ± 3·0	1·00
16	2·85 ± 0·412	14·6 ± 2·5	24·4 ± 4·0	< 0·01

to consider age as a more important factor than body-weight.

Experiments were carried out on piglets suckling regularly. As we discovered, even though intake and digestion of foods in piglets are important factors in metabolism, they cannot significantly influence the reported findings[2].

In conclusion it can be stated that development of chemical thermoregulation in the postnatal period of piglets occurs in three phases. Up to sixth-day thermogenesis, even if it exists, is unsatisfactory; from the ninth day it starts asserting itself, and around the twentieth day it is nearly perfect.

Glucuronic Acid Formation in Epiphyseal Cartilage Homogenate

IN a previous communication[1] the formation of hexosamine in epiphyseal cartilage homogenate of young rabbits was reported.

Cartilage was shown to synthesize the amino-sugar from glucose-6-phosphate and glutamine. The enzymatic fixation of sulphuric and acetyl radicals by cartilage has been reported by other workers[2,3]; we then envisaged the presence of all the enzymes concerned in chondroitin sulphate biosynthesis, inasmuch as chondroitin sulphate is largely present in cartilage and possibly connected with the fixation of calcium ions during the mineralization process.

Strominger *et al.*[4] have shown that the formation of glucuronic acid is accomplished through oxidation of uridine diphosphoglucose to uridine diphosphoglucuronic acid. This dehydrogenase was shown to be dependent on DPN+ and was isolated from calf liver by Strominger *et al.*[4].

We were therefore interested to see whether this enzyme was present in epiphyseal cartilage.

Epiphyseal cartilage of growing rabbits was used; the tissue was excised from proximal and distal ends of long bones at 0° C. and homogenized with cold water in a Potter–Elvehjem homogenizer. Two 10-ml. centrifuge tubes were used, each containing: 0·5 ml. cartilage homogenate (10 per cent), 1·5 ml. 0·014 *M* phosphate buffer *p*H 7·4, 20 μM magnesium chloride, 1 μM DPN+ and 1 μM of uridine diphosphoglucose (Sigma Chem. Co.). One tube immediately put in boiling water for 10 min. was taken as a blank; the other tube was incubated at 38° C. for three hours and the reaction was blocked as in the blank tube. In both tubes chondroitin sulphate was precipitated by the addition of 1 ml. of acetic acid and 2·5 ml. of ethanol (95%), and glucuronic acid was measured on the supernatant with the method of Dische[5].

Furthermore, we have studied the glucuronic acid formation omitting in the reaction mixture magnesium chloride or DPN+ or uridine diphosphoglucose, as well as replacing the last-named with uridine triphosphate and glucose-1-phosphate.

Table 1. GLUCURONIC ACID FORMATION IN EPIPHYSEAL CARTILAGE HOMOGENATES

Values obtained in 3 hr. at 38° C. and *p*H 7·4 for 100 mgm. of cartilage

No. exper.	DPN+ μM	$MgCl_2$ μM	UDPG μM	UTP μM	Glucose-1-P μM	Glucuronic acid μgm.
11	1	20	1	—	—	136
2	1	—	1	—	—	110
4	—	20	1	—	—	52
6	1	20	—	—	—	12
2	1	20	—	2	3	100

In Table 1 average values of some experiments are collected.

From Table 1 it appears that uridine diphosphoglucose is oxidized to uridine phosphoglucuronic acid by cartilage homogenate: the dehydrogenase which is responsible for this oxidation is dependent on DPN+, as reported by Strominger *et al.*[4], since omission of this nucleotide in the reaction mixture yields a reduced formation of glucuronic acid. Uridine diphosphoglucose may be substituted by uridine triphosphate and glucose-1-phosphate: this observation indicates that uridine diphosphoglucose can be synthesized from these compounds according to the reaction[6]:

$$\text{Uridine triphosphate} + \text{glucose-1-P} \rightarrow \text{uridine diphosphoglucose} + \text{pyrophosphate}$$

The capacity of cartilage to synthesize uridine diphosphoglucose is further support of the hypothesis that all the enzymes concerned in chondroitinsulphate biosynthesis are present in epiphyseal cartilage.

Lipotropic Action of Ethyl Trichloracetate

DURING a study of the biological effects of halogen derivatives of aliphatic acids, the effects of ethyl monochloracetate and ethyl trichloracetate on rat liver have been compared. Ethyl monochloracetate has a toxic effect on liver, whereas equimolecular doses of ethyl trichloracetate cause no apparent change. However, when ethyl trichloracetate is given subcutaneously to choline-deficient rats, the high level of liver lipid is significantly reduced.

Young rats were placed on a basic choline-deficient diet containing 8 per cent casein, 12 per cent gelatin, and 12 per cent fat, the diet being essentially similar to that used by Ridout, Lucas, Patterson and Best[1]. After 21 days, a group of animals was given six subcutaneous injections of 0·1 ml. of ethyl trichloracetate (approx. 720 μmoles) per 100 gm. body-weight over three days. Control animals and injected animals were killed after 24 days on the basic diet. Mean lipid content of livers from the control group was 18·6 per cent wet weight of liver and 9·6 per

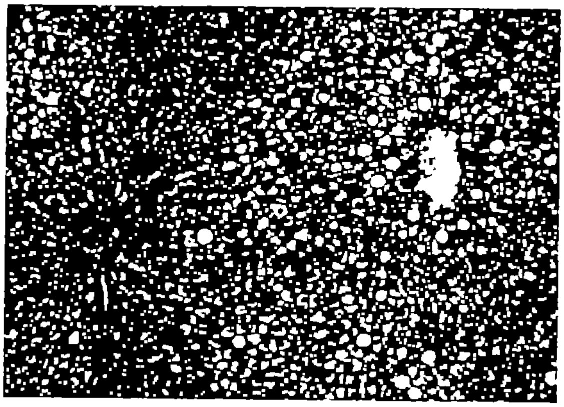

Fig. 1. Liver from choline-deficient rat. Hæmotoxylin and eosin. (×80)

cent for the injected group. This difference was statistically significant by the *t* test ($P < 0 \cdot 02$).

In another experiment, a group of twenty-four rats was placed on the choline-deficient diet. After 3 weeks, half the animals were given a weekly dose of 0·7 ml. ethyl trichloracetate in divided doses for 4 weeks. Control animals and those injected were killed after 7 weeks on the diet. The mean liver lipid content was 14·2 per cent wet weight of liver for the control group, while for the treated group the mean value was 7·5 per cent. This difference was significant ($P < 0 \cdot 001$).

Histological examination of livers of the choline-deficient group showed the accumulation of lipid in large and small globules about the centrolobular areas. This follows the usual pattern as described by Hartroft[2]. A section from a typical choline-deficient animal from the second experiment is shown in Fig. 1. The lipid content of this liver was 12·9 per cent. Livers from animals on the choline-deficient diet and receiving ethyl trichloracetate showed little fat in histological sections. Some livers showed a few large globules but usually the fat was present in such minute globules that it could not be recognized in routine hæmotoxylin and eosin sections. The histological appearance (Fig. 2) resembles that of normal liver, and the biochemical estimation of lipid in this liver was 6·2 per cent.

This lipotropic action of ethyl trichloracetate is of interest because of its chemical relationship to ethyl monochloracetate and the high toxicity of the latter.

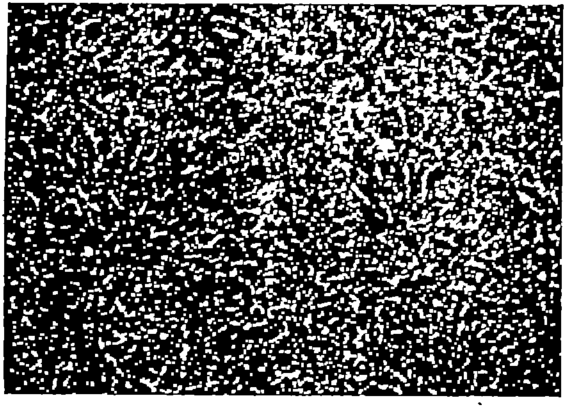

Fig. 2. Liver from choline-deficient rat injected with ethyl trichloracetate. Hæmotoxylin and eosin. (×80)

Publication of the complete results will follow this preliminary communication.

Chemical Nature of the Fluorescent Pigment produced in *Microsporum*-infected Hair

Since Margarot and Devèze[1], studying tinea capitis in man, discovered in 1925 that infected hairs would fluoresce upon exposure to ultra-violet light, extensive use has been made of this phenomenon both in diagnosis and in evaluating the progress of therapy. In spite of numerous studies of the properties of the fluorescent pigment[2–5], the chemical nature of the fungus metabolite responsible for fluorescence has not been discovered.

Microsporum canis Bodin and *M. gypseum* (Bodin) Guiart and Grigorakis were grown upon hair, which was moistened with a small quantity of distilled water and sterilized by autoclaving, and also upon the synthetic medium of von Mallinckrodt-Haupt and Carrié[6], for three to four weeks at room temperature. Fluorescence was never directly observable upon either medium. The fungus-infected hair was thereupon extracted with water by autoclaving for 15 min.[3]. Charcoal was added to the aqueous extract, and was removed by filtration[3]. To the charcoal was added a small quantity of methanol[3]. The methanol solution, after filtration to remove the charcoal and concentration by evaporation, was passed through a 1 cm. × 8 cm. column of alumina[4]. Culture filtrates from the synthetic medium were treated similarly. The resulting methanol solutions were strongly fluorescent, the intensity of fluorescence from infected hair being several times as great as that resulting from cultivation of the fungi on the synthetic medium.

Absorption spectra of the methanol solutions in the ultra-violet were taken with a model *DU* Beckman spectrophotometer. For both *M. canis* and *M. gypseum*, two absorption maxima were present, a larger one at 260–275 mμ and a smaller one at 330–335 mμ. Absorption spectra of the extract from *M. gypseum* in $N/10$ hydrochloric acid showed peaks at 260 and at 335 mμ, while in $N/10$ sodium hydroxide these were shifted to 280–285 mμ and to 350 mμ respectively. These characteristics indicate that the pigment is a pteridine[7], an inference which finds considerable support in the chemical studies of Davidson and Gregory[3] and Chattaway and Barlow[4], and the infra-red analysis of Robinson, Figge and Bereston[5].

Methanol solutions of the fluorescent pigments from *M. canis* and *M. gypseum* were chromatographed on strips of Whatman No. 1 filter paper by the ascending technique, using 3 N ammonium hydroxide or the organic phase of *n*-butanol : acetic acid : water (4 : 1 : 5, by volume) as the developing solvents. The spots were located by their fluorescence. For both *M. canis* and *M. gypseum*, a single spot was obtained with R_F values in the two solvents of 0·79–0·83 and 0·67–0·71 respectively. These findings would indicate that the fluorescent pigments of the two species of fungi are identical.

The fluorescence spectra of methanol extracts of *M. canis* and *M. gypseum* were studied with a model *DU* Beckman spectrophotometer modified by having the sample tube in the position of the usual light source. Excitation was provided by a General Electric 100-watt mercury lamp, type *S*-4. Fluorescence maxima for both species were found at 455–460 mμ, a value which differs considerably from that reported by Bereston and Crosswhite[8].

The properties of the fluorescent pigment produced by *M. canis* and *M. gypseum* indicate that it is a pteridine. Efforts to identify it with a known pteridine have been unsuccessful.

Complexity of the Vanadium - Hydrogen Peroxide System

THE reaction of quinquevalent vanadium with hydrogen peroxide, which is a well-known spot test[1] and the basis of a colorimetric[2] and volumetric[3] method for the estimation of vanadium, becomes rather complex on closer inspection. Depending upon concentrations and temperature of the reactants, this reaction can lead to four distinctly different forms.

(1) In alkaline solutions, concentrated in vanadium and hydrogen peroxide, the blue-violet tetraperoxy-orthovanadate ions[4,5] are formed in the cold relatively slowly:

$$VO_4^{3-} + 4H_2O_2 = (V(O.O)_4)^{3-} + 4H_2O$$

(2) An intermediate formed instantly in the above reaction is the yellow diperoxy-orthovanadate ion, $(VO_2(O.O)_2)^{3-}$, which is stable in dilute, weakly alkaline to weakly acidic solutions of alkalivanadates[5].

(3) In acidic solutions, the pale yellow pervanadyl ion[6-8], VO_2+, instantly forms the deep red-brown monoperoxy-pervanadyl cation, $(VO(O.O))+$:

$$VO_2+ + H_2O_2 = (VO(O.O))+ + H_2O$$

forms (2) and (3) being related by the equilibrium:

$$(VO_2(O.O)_2)^{3-} + 4H+ = (VO(O.O))+ + H_2O_2 + H_2O$$

(4) In strongly acidic solutions, on the other hand, a reduction[8,9] to the blue quadrivalent vanadyl ion, $VO^{2}+$, takes place relatively slowly:

$$2VO_2+ + 2H+ + H_2O_2 = 2VO^{2}+ + 2H_2O + O_2$$

the red-brown $(VO(O.O))+$ ions being formed instantly as an intermediate. The reduction occurs quantitatively and within a few minutes in concentrated sulphuric acid, and more slowly in 72 per cent sulphuric acid, or 72 per cent perchloric acid. It can be seen from Fig. 1 that heating up to 81° C. does not interfere with the quantitativeness of reduction. In dilute acidic solutions, reduction occurs considerably more slowly and is no longer quantitative, solutions in nitric acid showing less readiness to undergo reduction than those in sulphuric or perchloric acids of corresponding strengths.

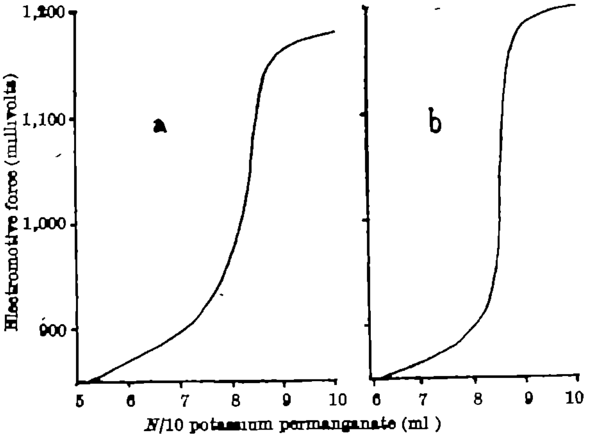

Fig. 1. Oxidation curves of VO^{2+} solutions with *N*/10 potassium permanganate after reduction with hydrogen peroxide (*a*) at 21° C. and (*b*) at 81° C. 0·1000 gm. ammonium vanadate was dissolved in 30 ml. 72 per cent sulphuric acid (w/w) in each case

When reversing the order of mixing, that is, first dissolving the vanadium (V_2O_5, or NH_4VO_3) in hydrogen peroxide (100 per cent by volume) and then acidifying the ensuing yellow solution of $(VO_2(O.O)_2)^{3-}$ relatively slowly with concentrated sulphuric acid, a reduction to the blue $VO^{2}+$ ion occurs quantitatively within a few minutes. We therefore recommend this procedure as basis of a selective method for the volumetric determination of vanadium.

It is evident from this review of the vanadium–hydrogen peroxide system that a colorimetric estimation of vanadium will require a low concentration of hydrogen peroxide, medium to low acidity (nitric acid in preference to sulphuric or perchloric acid), and a relatively low temperature. Similar considerations would apply to the spot test technique.

Detailed results of our investigation will be published elsewhere. We wish to acknowledge financial assistance from the British Cotton and Wool Dyers' Association and aid in apparatus from Imperial Chemical Industries, Ltd., Blackley.

Frequency Drift of Short-Time Transients in Solar Radio Noise

A DETAILED knowledge of the structure of solar noise storm bursts is essential for a theoretical treatment and understanding of the phenomenon. Different methods of observation have been tried in order to secure information on important physical quantities of storm bursts. In this communication some preliminary results are reported from an analysis of high-speed records which were taken with a receiver containing two channels centred at 199 Mc./sec. and 200·5 Mc./sec. (band-width: 0·3 Mc./sec., time constant 0·01 sec., and noise factor about 4). Records were taken with a double-channel Brush recorder at paper-speeds of 5, 25 and 125 mm./sec. Records have been obtained since February of this year during most noise storm periods.

A first inspection of the records gives the impression that the run of intensity versus time on the two frequencies often shows poor correspondence. This is in agreement with earlier observations, which have shown that storm bursts are of a highly monochromatic character. A more surprising feature, however, is the frequently occurring time difference between corresponding pips in the channels. Some good examples are shown in Fig. 1, *a*, *b*, *c*. In Fig. 1,*a* the low-frequency signal is in advance of that on the higher frequency, but in Fig. 1,*b*, the opposite is the case, while in Fig. 1,*c* the pips occur simultaneously. During a noise storm these three possibilities are all realized, but in different proportions. On April 28, out of 87 pairs of pips, 42 occurred at first on the low frequency, 29 occurred first on the high frequency, and 16 occurred simultaneously.

The simplest way to explain the observations is to suppose that the transients in most cases have a frequency drift from higher to lower frequencies, or vice versa. If this is assumed, observations indicate drift velocities in either direction ranging from about 10 Mc./sec.[2] and upwards to rather high values.

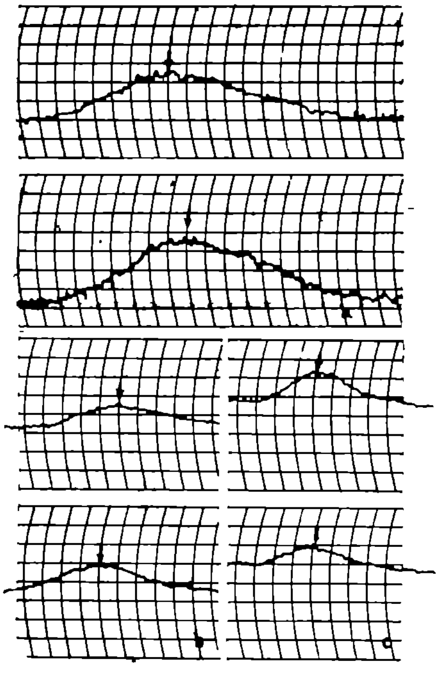

Fig. 1. Examples of records (Paper speed 125 mm./sec., lower-frequency above.) In (*a*) the pip occurs first on the low frequency, in (*b*) on the high frequency and in (*c*) simultaneously in both channels

Observations by Wild[1] with a spectrometer covering the frequency range 70–130 Mc./sec. showed that noise storm bursts had a mid-frequency which remained approximately constant throughout their life-time. However, since the rather extended spectral range covered was only displayed about three times a second, the instrument was not fitted for observations of transients with a duration less than, say, 0·5 sec. and a drift over only a few megacycles/second. This may be the reason why the effect dealt with here has not been reported earlier. The mean duration of the pips which were recorded with the two-channel receiver was of the order of 0·30 sec. A narrow-band spectrometer with a high frequency of repetition has now been erected at the Solar Observatory.

A fuller analysis of the records from the double-channel receiver is in preparation and the results will soon be published.

This investigation is being supported in part by the U.S. Air Force (ARDC, European Office).

Strength of Highly Porous Brittle Materials

THE experimental scatter in strength measurements of brittle materials is now accepted as reflecting the inherent statistical nature of this type of failure rather than an excessive sensitivity to measuring methods. Moreover, some characteristic features of brittle bodies, such as the scale effect, whereby geometrically similar test pieces of different absolute size give significantly different results, are easily explained on a statistical basis.

The fundamental work on these questions has been done by W. Weibull and by J. I. Frenkel and T. A. Kontorova, who base their theory on a random distribution of microscopic flaws in the material. These flaws weaken the material in their vicinity to different extents, the most 'dangerous' flaw determining the macroscopic strength of a homogeneously stressed test piece. At the back of these ideas is the old theory of 'Griffith's cracks', which are the cause of local stress concentrations, the severity of which depends on the size of crack.

These theories are satisfactory if they are to explain only the statistical nature of brittle fracture. The notion of a flaw, however, is too vague to give a clear-cut relation between the inherent strength of the material and the weakening effect of these flaws. The Griffith's crack, it is true, does give such a relation, but it forms a very special type of flaw; the number of such cracks per unit volume of the material is, moreover, usually assumed to be so low that the stress concentration in the neighbourhood of one is not affected by the presence of another crack. Neither the shape nor the concentration of

Griffith's cracks can be taken to form a reasonably correct model for highly porous materials such as, for example, set plaster of Paris. (This does not affect, of course, the validity of Griffith's crack theory in some individual crystals.)

On the assumption that the flaws which give the strength its statistical character are pores, a further development must, if possible, generalize with respect to shape of pore and porosity (percentage of void space in 1 c.c.). The difficulty lies in the fact that shapes of pores can be very complicated indeed. Set plaster of Paris, for example, can form a felted mass of acicular crystals with a very high porosity. The pores are interconnected and very different from any simple geometrical shape.

Progress was found possible by working out the results for a body riddled with a number of spherical pores and also for one which is permeated with tubular pores which twist and turn in a random fashion. The former can be taken as also approximately true for shapes which have roughly equal dimensions in all directions, while the latter is also approximately true for pores the dimension of which in one direction is much greater than in any direction at right angles to it. These two results, therefore, cover two very different types of pore shapes. Surprisingly, the two resulting formulæ have a very striking similarity and suggest a generalization which contains the derived formulæ as special cases. It is impossible to give here the mathematical derivation, which is rather lengthy and will be published elsewhere; but the essential result is the following relation between strength and porosity:

$$S = q \log \frac{p_{cr}}{p}$$

where S is the measured strength and p the porosity; q and p_{cr} are two constants referred to as the quality factor and critical porosity. It is a consequence of the theory that q may be interpreted as a measure for the inherent strength of the skeleton, while p_{cr} is the critical porosity at which the material would lose all strength. This latter constant is a geometrical feature of the pore system and, therefore, independent of the type of test; q, on the other hand, in accordance with the general behaviour of solid bodies with respect to mechanical strength, will assume different values for different tests.

In the case of set plaster, it can be shown that the porosity may be regarded as entirely due to the evaporation of the quantity of water in excess of that required for the complete hydration of the hemihydrate ($2CaSO_4.H_2O$) from which the plaster mix was made. The corrections which are, strictly speaking, required to allow for setting expansion (of the order of ½ per cent) and similar effects are small. The above formula has been verified by the results of strength tests on a considerable number of plasters differing in origin, method of calcining, conditioning of the set specimen, etc. The most convenient way of making comparison between theory and experiment is by plotting measured strengths against the logarithm of the porosity. The abscissa also carries a scale of water ratios (c.c. water per gm. of plaster used for the mix).

Fig. 1 represents the experimental results of compressive, transverse and tensile tests for a plaster, four water ratios having been taken for each type of test. The modulus of rupture as obtained from the transverse test is also shown for a second sample where six water ratios were selected. As expected from the theory, each test gives results lying on a straight line. The three lines obtained from the first sample all intersect the abscissa at the same point, namely, the critical porosity, which in this case is 0·79.

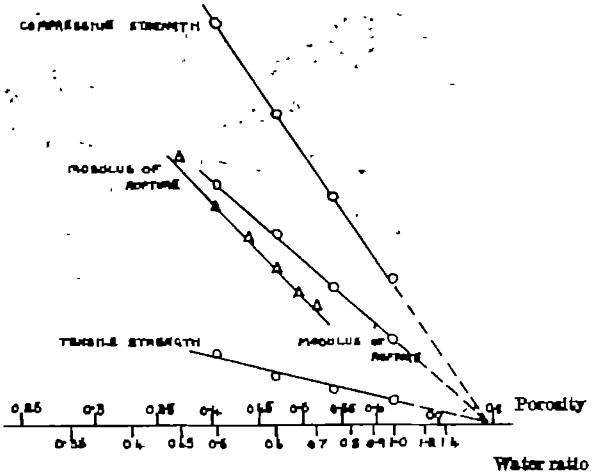

Fig. 1

The possibility of thus separating the effect of the inherent strength of the skeleton and the porosity promises to be of great practical value.

A Protein Antigen associated with Smooth Colony Forms of some Species of *Pasteurella*

On the basis of serological studies, *Pasteurella pestis* has been considered to be antigenically 'rough'[1], a view which is confirmed by the absence of an 'O' somatic antigen[2]. Virulent and certain avirulent plague strains, however, produce smooth colonies although rough strains also occur[3]. The rough forms referred to herein correspond to '*TSR*' and not '*TRU*'[4].

Analysis of the antigenic compositions of smooth and rough strains by the agar diffusion method of Ouchterlony[5] revealed that an antigen (antigen 4)[4] is present only in smooth forms and in maximal amount in well-aerated broth cultures incubated at 37° C. and at a pH close to neutrality. It is first detected after about 16 hr. of growth, and production reaches a maximum at the end of the log phase. It is not formed in detectable amounts by static broth or agar surface cultures. Although smooth and rough avirulent protective strains have not previously been differentiated antigenically, Otten[6], using living vaccines, showed that smooth strains gave better protection than those which were rough;

Table 1. Comparison of Plague Vaccines in Mice

Each of six serial 1 : 2 dilutions of bacterial suspensions (0·5 ml.) were injected intraperitoneally in two doses separated by an interval of one week into ten white mice. A week after the second injection animals were challenged with approximately 100 times the 50 per cent lethal dose of a virulent strain. This gave 100 per cent of deaths in control animals which had received two injections of a non-protective strain

Vaccine, strain Tjiwidej grown at 37° C.	HD50* (organisms × 10⁸) with 95 per cent fiducial limits	Relative potency of rough to smooth forms with 95 per cent fiducial limits
Smooth, killed	16 .. 32 .. 64	0·3 .. 0·7 .. 1·7
Rough, killed	11 .. 23 .. 48	
Smooth, living	0·23 .. 0·38 .. 1·08	0·008 .. 0·04 .. 0·13
Rough, living	5 .. 9 .. 42	

* The dose effective in protecting 50 per cent of the animals.

Schütze, however, who used dead vaccines, found both forms to be equally protective[3]. The results shown in Table 1 confirm these observations ; smooth and rough states of strain Tjiwidej (*TS*) killed in acetone at − 20° C. do not differ significantly in protective value, indicating that they contain similar amounts of protective ('envelope') antigen. Living rough cultures give a similar degree of protection to those which have been killed ; but living smooth cells give between 20- and 100-fold better protection than smooth organisms killed in the same way. Similar results have been obtained for smooth and rough pairs of strains other than *TS*. Since antigen 4 is the only difference in antigenic constitution which can be detected between smooth and rough strains, the results suggest that antigen 4 contributes to the survival of smooth organisms *in vivo*, thus prolonging the stimulus for protective antibody production. On this basis the results of Walker *et al.*[6], who studied protective values and survival-times *in vivo*, suggested that strain 14 possessed antigen 4 but no protective antigen. No strain of this type had previously been encountered, but examination of the culture has shown this induction to be correct.

Antigen 4 has been isolated from saline extracts of smooth *P. pestis* cells by precipitation with ammonium sulphate (15–23 per cent saturation). A preparation which satisfies the usual criteria of physical homogeneity is shown (Fig. 1) to pass, in addition, a most sensitive test for immunological homogeneity. The material is a protein, but unlike the 'envelope'[4] or antigen 3 does not induce production of protective antibodies, although it is much more potent as an antigen when the two purified materials are compared. Whereas smooth cultures are relatively stable in saline suspension, rough cells rapidly sediment. The addition of a purified preparation of antigen 4 to a suspension of rough organisms has a stabilizing effect such that they sediment no more rapidly than smooth ones. This effect could not be obtained with any of several other proteins, some of which had been isolated from *P. pestis* cells. It seems likely, therefore, that antigen 4 is related in some way to the smooth colonial form of an organism which is rough in the Salmonella sense.

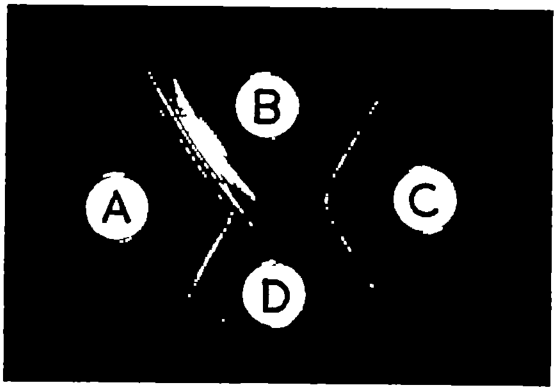

Fig. 1. Agar diffusion precipitin pattern of *Pasteurella pestis* cells and antigen 4. The antigen 4 preparation (*C*) gives only one line when reacting with an antiserum (*B*) which contains antibodies to all the antigens of smooth 37° C. grown organisms (*A*). Antiserum (*D*) prepared by immunization with the antigen 4 preparation reacts with these organisms (*A*) and antigen 4 (*C*) to give only one line. The arc on the right shows the specific identity of the antibody reacting from the serum at (*B*) and the monospecific serum at (*D*)

Whereas all smooth avirulent strains produced antigen 4 within 16 hr. under appropriate conditions, virulent strains did so only when growth was continued for a longer period. *Pasteurella septica* and *Pasteurella haemolytica* do not produce antigen 4, and judging from agar diffusion analysis their relationship to *P. pestis*, and indeed to one another, seems to be remote. *Pasteurella pseudotuberculosis*, however, shows a very close relationship to *P. pestis*[4,7]. All virulent *P. pseudotuberculosis* strains produced antigen 4 but neither smooth nor rough avirulent forms did so. It may thus represent a 'virulence' antigen in this species, although it is not a protective antigen in *P. pseudotuberculosis* infection. Smooth strains, unlike *P. pestis*, contain a specific smooth 'O' somatic antigen[8]. Strains which had lost their smooth 'O' somatic antigen and were smooth in colonial form have been encountered; these strains contained antigen 4, whereas frankly rough forms had lost both the 'O' somatic antigen and antigen 4.

We gratefully acknowledge the encouragement and advice of Dr. D. W. Henderson.

The Gum of *Fagara xanthoxyloides*

Fagara xanthoxyloides Lam. (*Xanthoxylum senegalense* DC.), a common plant in West Africa, exudes a clear yellow gum during the dry season. The gum is partly acetylated and has a significant methoxyl content. A single unpurified nodule gave, on analysis, acetyl groups, 6·95 per cent ; methoxyl groups, 2·6 per cent. The nodules dissolve with difficulty in water to give a viscous solution with a faintly acid reaction. The purified gum was obtained in the usual way[1], and after drying in a partial vacuum at 30° was a white amorphous powder, $[\alpha]_D^{21} + 4^\circ$ (c. 0·5 in *N* sodium hydroxide); equivalent weight by direct titration, 1,100 ; sulphated ash, 0·25 per cent ; nitrogen, 0·23 per cent ; acetyl groups, none ; methoxyl groups, 2·6 per cent (a polysaccharide of equivalent weight 1,100 containing monomethylhexuronic residues would have a methoxyl content of 2·8 per cent). It gave a positive naphthoresorcinol test for uronic acid, and failed to reduce Fehling's solution. Specimens prepared from nodules from different trees did not show any significant differences in optical rotations and equivalent weights, indicating the essential homogeneity of the gum.

A 0·5 per cent solution of the gum in 2 N sulphuric acid was heated for 20 hr. in a sealed tube immersed in a boiling water bath. The solution was neutralized with barium carbonate and then concentrated under reduced pressure to small volume. On paper chromatograms including reference substances and run in the solvent systems n-butanol–ethanol–water (20 : 1 : 3) (A), n-butanol–pyridine–water (3 : 1 : 1) (B), benzene–n-butanol–pyridine–water (1 : 5 : 3 : 3) (C), the sugars galactose and arabinose were detected. The papers were developed with p-anisidine phosphate and naphthoresorcinol–trichloroacetic acid sprays. The absence of ketoses was established by means of the last-named spray developer. A portion of the neutral hydrolysate obtained above was deionized by treatment with 'ZeoKarb 225' and chromatographed with the solvent system, ethyl acetate–acetic acid–formic acid–water (18 : 3 : 1 : 4) (D). On developing with p-anisidine phosphate, 4-O-methylglucuronic acid was detected as a pink spot moving at the same rate on the chromatogram as rhamnose[2].

Another portion of gum was hydrolysed as above, and the neutral hydrolysate concentrated under reduced pressure to a syrup. This was repeatedly extracted with boiling methanol, and the methanol extracts concentrated under reduced pressure to a syrupy mixture of neutral sugars. The syrup was resolved on large sheets of Whatman 3MM paper, the appropriate portions of the paper eluted with cold water, and galactose $[\alpha]_D^{21} = +81°$, and arabinose $[\alpha]_D^{21} = +104°$, characterized as mucic acid, m.p. and mixed m.p. 214–215°, and arabinose benzoylhydrazone, m.p. and mixed m.p. 206–207° (from ethanol), respectively.

Because of the extensive decomposition brought about by boiling sulphuric acid, quantitative estimation of the sugars was carried out on the product obtained by hydrolysing a portion of gum with 98 per cent formic acid[3]. A 2 per cent solution of the gum in formic acid was heated on the steam bath for 11 hr. The solution was evaporated under reduced pressure to a syrup and heated with N sulphuric acid for one hour to hydrolyse formyl esters. The solution was neutralized with barium carbonate, concentrated to a syrup and chromatographed on large sheets of Whatman No. 1 paper, with solvent system (A), with descending development for 72 hr. The appropriate portions of the paper were eluted with cold water and the amounts of sugars present estimated by the sodium periodate micro method[4]. A galactose–arabinose molar ratio of 7 : 3 was obtained.

The acidic products of the hydrolysis of the gum with 0·5 N sulphuric acid (17 hr. in a boiling water bath, $[\alpha]_D$ changed from c. $+4°$ to $+86°$) were isolated by pouring the neutralized hydrolysate, concentrated to small volume, into methanol. The precipitated material, after deionizing with 'Amberlite IR 120 (H)', was shown by chromatography with solvent (D) to consist of the barium salts of 4-O-methylglucuronic acid, an aldobiuronic acid and higher acidic oligosaccharides. The mixture was subjected to simultaneous methanolysis and esterification by refluxing with 8 per cent methanolic hydrogen chloride for 7 hr. The product, isolated in the usual way, was dissolved in water and reduced with sodium borohydride[5]. After destroying the excess borohydride with dilute acetic acid, and deionizing the solution by successive treatment with 'Amberlite IR 120 (H)' and 'IR 4B', the product was hydrolysed with sulphuric acid and chromatographed with solvent B. Two spots were obtained corresponding to galactose and 4-O-methylglucose ($R_{\text{Rhamnose}} = 0·9$).

Paper chromatographic examination of the progress of autohydrolysis, as well as of hydrolysis in very dilute sulphuric acid solutions, indicated that arabinose is liberated rapidly, followed by small quantities of galactose on more prolonged heating. Hydrolysis was accompanied in every case by an increase in the positive optical rotation, corresponding to the splitting of β-linkages.

The gum of *Fagara xanthoxyloides*, therefore, appears to be composed of labile L-arabinose residues, linked to a more resistant framework of D-galactose and 4-O-methylglucuronic acid units, thus bearing a superficial resemblance to gum myrrh[1].

Possible Occurrence of Strains in Species of Schistosomes

IN a recent paper Cridland[1] has stated among his conclusions that there is no evidence for the occurrence of strains in human schistosomes and also that he had found that certain species of snail did not appear to act as carriers. For example, he states that *Bulinus africanus ovoideus* (Bgt.) will not act as a carrier of *Schistosoma haematobium* in Uganda, on the evidence that he had not been able to infect it in the laboratory. In the Kitui area of Kenya *Bulinus* (*Physopsis*) *africanus ovoideus* (Bgt.) and *B.* (*P.*) *nasutus* (von Marts.) both occur in ponds, dams and streams. The latter snail is common also in the coastal regions of north-east Tanganyika and is, in my opinion, quite different from the snail occurring in the Great Lakes which Mandahl-Barth[2] recorded as *nasutus*. He agrees with me that different sub-species are involved.

Bilharzia is frequent in the Kitui area of Kenya and *B. africanus ovoideus* has been demonstrated to be a carrier by the reliable method of identifying the adult worms. This was carried out by Drs. Teesdale and Nelson of the Division of Insect-Borne Diseases, Nairobi, with naturally infected material. This suggests, therefore, that either *B. africanus ovoideus* or *Schistosoma haematobium* or perhaps both exist in different strains. It seems more probable that the parasite exhibits strains but the species of *Bulinus* are rather plastic. The identification of the snails has been checked by dissection and also confirmed by Dr. G. Mandahl-Barth.

Anatomy of *Polystoma integerrimum*

THE remarkable dimorphism of the monogenetic trematode *Polystoma integerrimum* has been the subject of a number of investigations, principally by Zeller[1,2] and Gallien[3]. The descriptions of the neotenic (branchial) form given by these authors show several important discrepancies, and in view of this a re-examination of the species was undertaken.

Previously undescribed details of the anatomy of the normal or bladder form are as follows:

The material from which the anchors are formed is produced by clusters of secretory cells. The caudal suckers are supported by radiating cuticular bars which pass through the tissue of the sucker wall. Cuticular rays are known to form part of an intricate framework supporting the sucker in related genera, but have not been observed in *Polystoma*.

A median intestinal process extends forward beneath the pharynx and communicates with the buccal tube, forming a continuous canal underlying the pharynx and œsophagus and providing an alternative passage between oral cavity and intestine. For this passage the term 'bucco-intestinal canal' is suggested. The animals occasionally expel intestinal contents through the bucco-intestinal canal when disturbed; perhaps residual products of digestion are normally voided from the gut in this manner. Vital staining with methylene blue reveals a complex nerve ring surrounding the canal.

The male and female genital ducts have a syncytial lining, which is ciliated except in the terminal portions of the female canal holding the shelled egg. The cilia penetrate to the base of the epithelium; their activity resembles the flickering motion of the flames of the excretory system.

The ovary comprises a small anterior proliferative zone and a large posterior portion in which ripe oocytes are stored. The posterior portion of the ovary has an epithelial wall; each of the oocytes is enclosed in a delicate envelope formed from membranous extensions of the free border of the epithelium.

Two distinct groups of unicellular glands are associated with the ootype. The cells of the smaller group produce a deeply staining secretion, and their ducts open in a restricted region at the proximal end of the ootype. The secretion may play some part in egg capsule formation. The cells of the larger gland mass form a coarsely granular secretion which is faintly cyanophilous and gives a strong positive reaction to Steedman's alcian blue test for mucin[4]. The numerous, tightly bunched ducts empty through the entire ootype wall. The lubricating property of the mucin may facilitate the moulding of the egg capsules and the passage of the shelled egg along the uterus.

In the neotenic adult also the anchors are formed from the product of small secretory cells, and the suckers are supported by cuticular rays. The bucco-intestinal canal is present in both the neotenic adult and the larva. The oocytes of the branchial form are enclosed in membranous envelopes continuous with the ovarian epithelium. Both types of unicellular gland associated with the ootype differentiate in the neotenic form.

The definitive spermatozoon of the neotenic adult resembles the late spermatid of the normal adult.

It was found during the present investigation that, contrary to earlier accounts, there is no communicating canal between the testis and the female ducts of the neotenic adult. The vas deferens is present as in the normal form; this duct was observed by Zeller but was not described by Gallien. Although not previously identified, the genito-intestinal canal is present and functional as in the normal adult. The vaginæ and long winding uterus of the bladder form are not represented in the branchial form.

The histological appearance of the genital ducts of the branchial form is similar to that of the corresponding ducts of the normal adult.

During normal development the uterus and vaginæ are the last of the genital ducts to be differentiated, and the young normal form closely resembles the neotenic adult.

Since there is no duct connecting male and female organs in the branchial form, internal self-fertilization does not take place. Sperm bundles are found in the female ducts of solitary neotenic adults, and therefore external self-fertilization must occur, insemination being effected through the ovo-vitelline duct. When two neotenic adults parasitize the same tadpole cross-fertilization through the gonopore may occur. Thus, *within the one species* the copulatory function presumably is transferred from the vaginæ to the ovo-vitelline duct as a result of neotenic development.

The completed study of the anatomy of *Polystoma integerrimum* will be published later, together with notes on the life-history and relationships of this species and observations on related genera.

Potato Blight and Leaf-Roll Virus

OBSERVATIONS on the potato variety Ulster Supreme made at Cambridge in 1956 indicated that blight (*Phytophthora infestans*) was present on approximately twice as many tubers derived from plants infected with leaf-roll virus as on those from neighbouring virus-free plants (virus-free being used in this communication to mean free from visible symptoms of virus disease). The appearance of potato blight in August 1957 made possible an examination and comparison of the foliage of virus-free and leaf-roll infected plants. At an early stage in its development it was apparent that the primary foci of infection were often associated with patches of plants infected with leaf-roll virus and that some plants within these patches were completely destroyed at a time when surrounding virus-free plants were only slightly or moderately blighted. Leaves picked on three occasions from an area showing 50 per cent leaf-roll infection, from the same level of the crop and showing no visible blight lesions, were incubated. On each occasion blight lesions developed on about half the rolled virus-infected leaves whereas none developed on those which were virus free.

Laboratory tests using leaf pieces sprayed with a zoospore suspension, as described by Müller[1], indicated that leaf-roll infected leaves were less susceptible to infection than virus-free leaves. Results of three tests gave 55 per cent infection on virus-free pieces and 37 per cent on leaf-roll pieces (the individual results being 84, 56, 26 and 67, 33, 11 per cent respectively). It was noted that the rate of advance of the fungus was much slower on leaf-roll infected leaflets than on virus-free ones. This condition is similar to that described by Müller and Munro[2] for potato leaves infected with virus *X* and virus *Y*. In addition, preliminary tests on tubers indicated that those infected with leaf-roll virus were not more susceptible to blight than those virus free.

Examination of potato foliage during bright periods following heavy showers showed that rolled leaf surfaces remained damp for longer periods than flat leaf surfaces and that many rolled leaflets held water to a depth of several millimetres until shaken out by the wind or slowly evaporated. It is suggested that the micro-climate of rolled virus-infected leaflets is more conducive to blight development for longer and more frequent periods than that of virus-free leaflets and that this is more than sufficient to overcome the slower rate of advance of the fungus on the former. Furthermore, the difference between micro-climates would account for the greater prevalence of blight on tubers derived from leaf-roll infected plants. Experiments to confirm this are in progress and will be reported elsewhere.

Growth and Properties of Bacterial Protoplasts

Previous papers on the subject of bacterial protoplasts prepared by the action of lysozyme indicate that the authors have been unable to observe growth and division of these structures over a prolonged period[1–3], although indications of activity in this direction have been obtained[4,5].

From preliminary experiments performed in this laboratory, it appeared that the reason for this failure to grow lay in some factor inherent in the enzymatic method of protoplast release, inhibitory to active growth and division. A method was developed which permitted the release and prolonged growth of protoplasts of a wide range of bacteria without employing extracellular 'enzyme-stabilizing' systems[2]. Bacteria were grown in a fluid medium containing 3 per cent w/v α-amino acetic acid (glycine) in 4-ml. amounts in 15-ml. screw-cap bottles, rotated at 22 revolutions per hour. The initial *p*H of the medium was 7·0, and the incubation temperature was 34° C.

Bacteria sensitive to this treatment lost their cell walls in a few hours, and a dense growth of protoplasts was obtained in 18–24 hr. In many species no vegetative cells could be detected and the protoplasts so formed could be propagated for prolonged periods in pure culture, without the appearance of any vegetative cells.

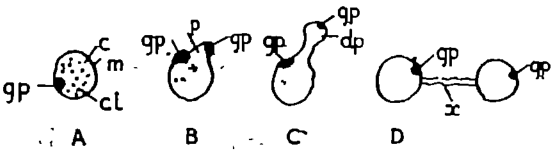

Fig. 1. *A*, Structure of protoplast (*g.p.*, growing point; *c.*, cytoplasm; *c.i.*, cytoplasmic inclusions; *m.*, membrane). *B–D*, Division of protoplast (*p.*, protrusion formed in early stages, swells at tip to form daughter protoplast, *d.p.*); the connexion between the two cells degenerating, *x*

The majority of studies were made upon *Vibrio cholerae*, *V. el Tor*, *Salmonella typhi*, *S. typhimurium*, *S. paratyphi* B. and a number of other bacteria of enteric origin.

By this method many of the properties of protoplasts have been investigated, and these are listed here very briefly.

(1) Membrane secretion, growth and division is controlled by a growing point granule consisting of lipoprotein in association with Feulgen-positive nuclear material[6] (Fig. 1).

(2) Reversion to vegetative forms, and further reorganization to the L-form, may be obtained under suitable conditions without difficulty.

(3) Diminution in size and increase in resistance to the inducing agent as serial subculture continued.

(4) Protoplasts have also been observed occurring naturally in pond and other natural waters, and as a response to senescence in laboratory cultures.

(5) The rate of fall of viable count in cultures of protoplasts rotated at 34° C. appears to be considerably less than in parallel cultures of homologous strains of *Vibrio cholerae* in the vegetative form.

X-Ray Interferences of Barium Sulphate in Fungi and Algae

In a paper on the constitution of cell walls of fungi, R. Frey[1] concludes that several fungi and algae show in their cell contents or membranes an inorganic substance with an X-ray diagram corresponding to that of barium sulphate. Since, in our researches on cell-walls of fungi[2,3], X-ray interferences suggesting the presence of that substance were never observed, some further work was done in order to check Frey's statements.

Frey subjected his cultured fungi to a standard extraction procedure with alkali and then in most cases found the residue to produce the interferences in question.

We investigated *Saccharomyces cerevisiae* and *Mucor rouxianus*, two of the many species in which Frey reports these interferences as dominant in the X-ray diagrams of his residues. Our results with these species were negative; neither by X-ray diffraction patterns of residues from extraction, nor by chemical analysis of the ashed fungi, have we been able to detect barium sulphate. For this and other reasons, in particular the occurrence of barium oxide in certain laboratory glasses and its solubility in alkali, it seems possible that Frey's observations on at least the fungi are due to contamination by the chemical treatment*.

Of the few algae investigated by Frey, *Spirogyra* was selected for a check. In this genus E. Nicolai (private communication to R. Frey and D. R. Kreger) has also observed X-ray interferences resembling those of barium sulphate, and she was the first to observe the phenomenon. The interferences were reported to appear in samples of dried natural filaments. Since these interferences cannot be due to contamination, we were interested in investigating this genus.

The X-ray diagrams of our *Spirogyra* samples likewise showed barium sulphate interferences.

We have tried to find if barium sulphate is actually the source of the interference lines. It could be shown both by X-ray diffraction of extracted material and of the ash and by chemical analysis of the latter that this substance is indeed present in the algae. The quantities amounted to 0·2–0·4 per cent of the dry weight. Algae from quite different types of fresh water contained such large amounts.

By examining separate cell walls and cell contents evidence was obtained that the mineral should not be regarded as part of the cell-wall, even though under certain artificial conditions its crystallites may show a preferential orientation with reference to the wall surface.

It may be noted that in higher plants barium is not an unusual minor element[4]. In a few species it has been found in amounts comparable to those mentioned above if the soils were rich in exchangeable barium[4]. The barium content of these plants roughly followed that of the soils, and therefore do not seem to be so much a result of accumulation as in *Spirogyra*.

Details of this research will be published elsewhere. The work has been supported by the Netherlands Organization for Pure Research (Z.W.O.).

**Note added in proof.* Prof. Frey-Wyssling informs me that micro-analyses of Frey's fungi were made at Zurich after his paper had appeared. Barium could not be detected. This supports the above views concerning its origin in Frey's alkali extracted specimens, as does the fact that I obtained barium sulphate from alkali stored at 60° C. in certain types of Erlenmeyer vessels.

The Treatment of the Mentally Ill

The otherwise excellent article "The Treatment of the Mentally Ill" in *Nature* of August 10, p. 253, contains one surprising paragraph in which reference is made to "the excessive safeguards against wrong certification (which are now unnecessary)" and "In practice, the average psychiatrist rarely certifies anyone".

These remarks do not agree with the facts of the case, which are that, while the total number of admissions to mental hospitals has increased during recent years, the number of certified patients has not substantially decreased over the past twenty-five years, but remains static in the region of 20,000 annually, with only a slight decrease to 17,500 in 1956.

The writer of the article could not, I think, have read the several Parliamentary debates during the past year in which Mr. Norman Dodds, myself and others—including Dr. A. D. D. Broughton, the only practising psychiatrist in the House—have commented on the hasty and frequently unnecessary use of compulsory certification powers. It must be repeated that a single doctor, who need not be a psychiatrist, can under present law certify a patient after a minimum period of observation.

The Royal Commission only suggested the elimination of present 'safeguards' because they are obviously illusory and ineffective. Its proposals contain alternative safeguards which it is hoped will be more effective in preventing the unsatisfactory use of compulsory powers which are so prominent a feature of the mental illness picture to-day.

The statement that "the scarcity of beds leads to patients being discharged too early rather than to their being unduly detained", which this paragraph also contains, does not correspond with the facts in numerous cases that have come to my notice over the past twelve months.

Donald McI. Johnson

House of Commons,
London, S.W.1.

Excessive safeguards against wrong certification exist inasmuch as a magistrate, who is unlikely to be instructed in mental illness, is included in those signing the document. In any event, although some 20,000 people are certified annually, it is very rare for genuine complaints of wrong certification to come to light. Most cases claiming it are in patients suffering from paranoid delusions of persecution. The few cases supported in the courts have been those of border-line mental deficiency (usually after some delinquency).

The average psychiatrist rarely certifies patients. Many patients are certified on what is known as a 'three-day order', which confines them to an observation ward for psychiatric investigation by an experienced medical man. A large number of these are never sent to a mental hospital but discharged.

As regards the question of scarcity of beds, we are informed that it is a matter of daily clinical experience to find that patients are being discharged prematurely. Editors.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, October 28

Faraday Society (in the Lecture Theatre of the Department of Physical Chemistry, University of Cambridge, Free School Lane, Cambridge), at 4.30 p.m.—Prof. W. Jost (University of Gottingen): "Reactions in Detonations and Shock Waves"* (Bourke Lecture).

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Mr. A. J. Shorter: "Historical Geography of English Paper Mills, 1495–1800".

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Informal evening on "Domestic High-Fidelity Reproduction". Talk by Mr. J. Moir.

University of London (in the Assembly Hall, Institute of Education, Malet Street, London, W.C.1), at 5.30 p.m.—Mr. R. A. R. Tricker "Physical Science"* (Fourth of a series of lectures on "Contemporary Ideas on Teaching Method".)

Tuesday, October 29

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. S. W. Wooldridge: "The Heritage in Physiographic Insight".* (First of six lectures on "The Heritage of the English Countryside". Further lectures on November 5, 12, 19, 26 and December 3 and 5.)

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. J. P. Shillingford: "The Study of the Circulation by Dye Curves".* (Fourth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation. Further lectures on October 31, November 5, 7, 12, 14, 19, 21, 26, 28, December 3 and 5.)

Society of Cosmetic Chemists of Great Britain (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7.30 p.m.—Dr. A. J. P. Martin: "Gas-Liquid Chromatography".

Wednesday, October 30

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. J. Sutton and Dr. J. V. Watson: "The Structure of the Ground South of Loch Duich, Ross-shire"; Dr. H. I. Drever and Mr. R. Johnston: "The Lower Margin of the Shiant Isles Sill (Outer Hebrides)".

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Mr. M. Telford: "Tropospheric Scatter System Evaluation".

Society for Analytical Chemistry, Microchemistry Group (in the restaurant room of "The Feathers", Tudor Street, London, E.C.4), at 6.30 p.m.—Discussion on "British Standards in Microchemistry", opened by Mr. C. Meredith and Mr. G. Ingram.

Institution of Mechanical Engineers, Education Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—Discussion on "The Place of Kinematics of Mechanisms in Engineering Curricula".

Thursday, October 31

Faraday Society (in the Lecture Theatre, Inorganic Chemistry Laboratory, South Parks Road, Oxford), at 5 p.m.—Prof. W. Jost (University of Gottingen): "Flame Reactions"* (Bourke Lecture).

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. Rosemary Biggs: "Hæmophilia and Christmas Disease".* (Fifth of fifteen lectures of "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation. Further lectures on November 5, 7, 12, 14, 19, 21, 26, 28 and December 3 and 5.)

University of London (in the Swanley Hall, Wye College, Wye, near Ashford, Kent), at 8.15 p.m.—Mr. N. Tinbergen: "Some Problems of Animal Behaviour".*

Friday, November 1

Association of Applied Biologists (in the Lecture Hall of the British Museum (Natural History), Cromwell Road, South Kensington, London, S.W.7), at 10.50 a.m.—Symposium on "Domestic Insects and Allied Pests".

North East Coast Institution of Engineers and Shipbuilders (in the Lecture Theatre of the Literary and Philosophical Society, Newcastle-upon-Tyne), at 6.15 p.m.—Mr. C. C. Pounder: "The Marine Diesel Engine" (Andrew Laing Lecture).

British Glaciological Society (in the Geography Department, The University, Downing Place, Cambridge), at 8.30 p.m.—Mr. J. F. Nye: "Glacier Waves—Observation and Theory (Cambridge Austerdalsbre Expedition)".

Royal Institution (at 21 Albemarle Street, London, W.1)—at 9 p.m.—Sir Hugh Beaver, K.B.E.: "Clean Air—What We Know and What We Do Not Know".

Saturday, November 2

British Interplanetary Society (in the Tudor Room, Caxton Hall, Caxton Street, London, S.W.1), at 6 p.m.—Dr. J. W. S. Pringle, F.R.S.: "Conditions for Life".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Scientific Officer (British subject normally resident in the United Kingdom, with an honours degree in agriculture or agricultural botany (or equivalent qualification) and a sound knowledge of the principles of genetics and practical plant breeding, and preferably with previous experience in the design and analysis of field trials) in the Plant Breeding Division, Ministry of Agriculture, Loughgall, Co. Armagh—The Secretary, Civil Service Commission, Stormont, Belfast (October 30).

Research Assistant (with postgraduate research experience, preferably in solid state physics) in the Department of Physics, for investigations on the magnetic properties of some of the transition elements and their alloys at high temperatures—The Registrar, The University, Sheffield (October 31).

Sandoz Research Fellow (with a medical qualification), for work in the Medical Unit on the effects of vasoactive peptides on the human circulation—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2 (October 31).

Assistant Lecturer (with a science qualification and preferably a medical qualification) in Physiology—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2 (November 1).

Lecturer in Biochemistry—The Secretary, The Queen's University of Belfast, Belfast, Northern Ireland (November 1).

Head (highly qualified in physics, and with suitable industrial and/or research experience, and some full-time and/or part-time university or technical college lecturing experience) of the Department of Physics (Grade IV), Brunel College of Technology, Woodlands Avenue, Acton, London, W.3—The Clerk to the Governing Body, Middlesex County Council Education Department, 10 Great George Street, London, S.W.1 (November 2).

Lecturer (graduate, with research and/or industrial experience, and experience in an important branch of applied chemistry, preferably polymers, plastics or dyeing) in Chemistry—The Principal, Derby and District College of Technology, Normanton Road, Derby (November 2).

Lecturer in Mechanical Engineering—The Registrar, The Manchester College of Science and Technology, Manchester 1 (November 8).

Dairy Officers (with a university degree in an agricultural science, preferably in dairying, or with postgraduate qualifications in dairying) in the Ministry of Agriculture, Federation of Rhodesia and Nyasaland—The Secretary (R), Rhodesia House, 429 Strand, London, W.C.2 (November 9).

Research Fellow (graduate of any British university) in Biochemistry or Microbiology—The Registrar, The University, Sheffield (November 9).

Experimental Officer, Grade 3 (with a degree or diploma with chemistry as a major subject and several years relevant experience) in the Defence Standards Laboratories of the Department of Supply, Australian Defence Scientific Service, Maribyrnong, Victoria, Australia, to undertake investigational work on the field of protective clothing and respirators—The Senior Representative (AP 84), Department of Supply, Australia House, Strand, London, W.C.2 (November 14).

Assistant Lecturer in Geography at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, November 15).

Lecturers (2) or Assistant Lecturers (2) in the Department of Physics—The Registrar, The University, Leeds 2 (November 18).

Lecturer in Physics at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 28).

Plant Pathologist (with a good honours degree in botany, including mycology, and postgraduate research experience), for research on fungal diseases of fruit—The Secretary, East Malling Research Station, near Maidstone, Kent (January 1).

Tucker-Price Research Fellow (woman graduate of any university), for research in mathematics, natural science, or an allied subject—The Secretary, Girton College, Cambridge (January 15).

Aerodynamicist (with a first- or second-class honours degree or equivalent in physics, mathematics or engineering) at the Ministry of Power Safety in Mines Research Establishment, Sheffield, for new research programmes involving aspects of fluid mechanics ranging from shock tube flows to mixing of different densities at low speeds, also to act as consultant to the Establishment on aerodynamic problems—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.309/7A.

Biochemical Technician in the Metabolic Unit—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2.

Deputy Director (with a good honours degree in some branch of natural science and considerable research experience) of Agricultural Research, Federation of Nigeria, to take charge of one division of the Federal Department of Agriculture (Botany, Entomology, Soil Chemistry, Agronomy, or Plant Pathology) and to assist in the administration of the Department—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD/63/14/042.

Lecturer or Assistant Lecturer in Physical or Inorganic Chemistry at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

Lecturers (with a degree or equivalent, and preferably industrial and/or teaching experience) in Telecommunications; and an Assistant Lecturer (Grade "B") in Telecommunications—The Clerk to the Governors, Northern Polytechnic, Holloway, London, N.7.

Metallurgist (male, with an honours degree) in the Physical Chemistry Section of the Chemistry Department in the Battersea

(London) Laboratories, for research work on the physical chemistry of ferrous metallurgical processes—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "O.P.S".

PHYSICIST (with a good honours degree), for experimental research on convection in fluids—Prof. P. A. Sheppard, Meteorology Department, Imperial College, London, S.W.7.

PHYSICISTS (with a degree or equivalent, and preferably experience in X-ray crystallography or, alternatively, an interest in this field with some research experience) at the Research Laboratories, Leatherhead, Surrey, for work on X-ray diffraction analysis—The Director of Establishments, Central Electricity Authority, Winsley Street, London, W.1, quoting Ref. N/436.

PHYSIOLOGICAL LABORATORY SUPERINTENDENT (with experience in laboratories of a teaching institute, a specialized knowledge of physiology and biology, and able to maintain physiological apparatus) in the Nigeria Northern Region Medical Department, for duties which include assistance in laboratory work to trainee pharmacists—The Crown Agents, 4 Millbank, London, S W.1, quoting M.3/44413/NF.

RESEARCH ASSISTANT (with a degree in zoology and interested in the development of cytological and/or physiological techniques) IN THE DEPARTMENT OF ZOOLOGY—The Registrar, The University, Nottingham.

RESEARCH ASSISTANTS (2) (preferably with a degree in electrical engineering or physics) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING (one to work on the development of a new solid-state device; and one on the development of a new beam-scanning principle in echo-ranging)—The Professor of Electrical Engineering, The University, Birmingham 15.

SCIENTIFIC OFFICERS (with a first- or second-class honours degree, preferably in physics or mathematics) IN THE METEOROLOGICAL OFFICE, for duties which include research in atmospheric physics, covering the study of cloud structure, synoptic and dynamical meteorology, large- and small-scale diffusion and turbulence, climatology and the development of instruments—The Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting No. S.52/57 (Met.).

SENIOR LECTURER IN PHYSICS; and a LECTURER IN PHYSICS—The Clerk to the Governors, Northern Polytechnic, Holloway, London, N.7.

SENIOR LECTURER (preferably with an active interest in research in some branch of applied mathematics) IN MATHEMATICS, to teach up to degree standard; a LECTURER IN MATHEMATICS, to teach pure and applied mathematics to degree standard; a LECTURER (preferably with industrial experience, and research interests in physical or inorganic chemistry) IN CHEMISTRY, to teach up to degree standard; and an ASSISTANT LECTURER (with teaching experience) IN CHEMISTRY (Grade B)—The Clerk to the Governors, Northern Polytechnic, Holloway, London, N.7.

TECHNICIAN (with university or L.M.L.T. qualifications), for biochemical research—The Secretary, Institute of Psychiatry, The Maudsley Hospital, Denmark Hill, London, S.E.5, quoting Ref. M.R.C. B.10.

X-RAY CRYSTALLOGRAPHER (at least Ph.D. standard, and preferably with several years experience), for work on fibrous proteins—The Director, Medical Research Council, Biophysics Research Unit, King's College, Strand, London, W.C.2.

Phoenix glass tubing meets everyone's requirements

Remarkable versatility is an everyday matter for Phoenix. It can be trusted to the most remarkable shapes without fear of fleddage or distortion.

Workability is only one outstanding quality of Phoenix. Its low coefficient of expansion prevents thermal shock and overcomes this particular danger of glass in working.

You can see through Phoenix glass clearly to check flow and density. Yet Phoenix possesses very high mechanical and thermal strength. It is produced by the latest thermal methods to ensure unvarying bore and roundness. For many of modern industry's most advanced techniques the most practical medium of all is Phoenix glass.

AVAILABLE IN 14 LB. STANDARD BUNDLES

Phoenix Heat Resisting glass tubing is packed in 14 lb. standard bundles—useful for the small and large user. While standard sizes are available ex stock, special requirements can be dealt with promptly. May we send you our catalogue?

PHOTOGEOLOGY

An evening course of nine lectures with practical work will be given by R. L. Birch, B.Sc. (Overseas Geological Surveys) on the geological interpretation of aerial photographs, on Wednesdays, 6 to 9 p m, commencing January 15, 1958. The course is intended for advanced students and graduates in Geology

The number of places is strictly limited and early application is advisable Further information may be obtained on application to the Head of the Department.

Principal: J. Topping, M.Sc., Ph.D., D.I.C, F.Inst.P

MATHEMATICS FOR INDUSTRY

A four year Sandwich Course for the Diploma in Technology in Mathematics will commence in January, 1958. Practical techniques useful for students intending to make a career in industry form a vital part of the course.

Details may be obtained from the Head of the Mathematics Department, to whom early application should be made.

C. E. GURR, M Sc, Ph.D,
Secretary to the Education Committee

OFFICIAL APPOINTMENTS

NATIONAL COLLEGE OF RUBBER TECHNOLOGY

HOLLOWAY, LONDON, N 7

Immediate applications are invited for the following teaching appointments, which provide opportunities for personal, and to teach, research:

(a) SENIOR LECTURER IN RUBBER TECHNOLOGY with considerable practical experience in the rubber industry and professional and/or academic qualifications. Salary scale, £1,400 by £50 to £1,600.

(b) SENIOR LECTURER IN PHYSICAL TESTING OF POLYMERS with laboratory experience in research and/or industrial organizations dealing mainly with rubbers. Salary scale, £1,400 by £50 to £1,600

(c) LECTURER IN RUBBER ENGINEERING. A qualified young engineer prepared to treat rubber as an engineering material, particularly in dynamic applications Salary scale, £1,250 by £30 to £1,400

(d) LECTURER IN POLYMER CHEMISTRY Science graduate prepared to teach polymer chemistry and to work on colloid dispersions. Salary scale, £1,250 by £30 to £1,400.

Apply, stating post in which interested, for application form and further particulars to the Clerk to the Governors.

FEDERATION OF NIGERIA

DEPARTMENT OF FOREST RESEARCH
RESEARCH OFFICER (BOTANY)

To investigate the physiological factors influencing seed germination and seedling development of trees in Nigerian forests, entailing field studies as well as experimental work under controlled environmental conditions; and to undertake general duties of a research officer Candidates must have a first- or second-class honours degree in botany, with some experience of research and special interest in ecology and/or plant physiology. Appointment on contract/gratuity terms for two tours of from 18 to 24 months Salary including inducement addition in range £870 to £1,824 with gratuity of £25 to £37 10s. for each completed period of three months satisfactory service payable on completion of engagement Outfit allowance £60 on first appointment. Free passages for officer, wife and up to two children under 18 on appointment and leave. Government quarters when available at moderate rental. Taxation at local rates.

Apply, giving brief particulars, to Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD./61/14/09

AUSTRALIAN NATIONAL UNIVERSITY

CANBERRA
JOHN CURTIN SCHOOL OF MEDICAL RESEARCH

The Electoral Committee for the Chair of Experimental Pathology wishes it known that it will shortly consider nominations in order to make a recommendation for appointment to the Chair and invites interested and qualified scientists to inform the undersigned from whom a statement* of further particulars may be obtained, before November 30, 1957. The Department of Experimental Pathology is a research department and the salary of the Professor will be £A.3,550 per annum. Reasonable travel and removal expenses are payable. One year's study leave with travel allowance will be granted after each three year's service

Notwithstanding this notification the University retains the right to fill the Chair by invitation.

R. A. HOHNEN,
Registrar

Box 4, G.P.O.,
Canberra, A.C.T., Australia

*This statement may also be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C.1.

UNIVERSITY OF LIVERPOOL

HARRISON CHAIR OF MECHANICAL ENGINEERING

The Council of the University invites applications for the Harrison Chair of Mechanical Engineering. The appointment will date from October 1, 1958.

Further particulars may be obtained from the undersigned, by whom twelve copies of applications (one in the case of overseas candidates), should be received not later than November 30, 1957.

STANLEY DUMBELL,
Registrar.

LIBYA

The National University of Libya wishes to appoint British staff to the following posts in the new Faculty of Science opened in Tripoli this month:

1. Assistant Lecturer in Chemistry.
2. Assistant Lecturer in Physics.
3. Assistant Lecturer in Botany.
4. Assistant Lecturer in Zoology.
5. Laboratory Technician in Chemistry.
6. Laboratory Technician in Botany and Zoology.

British university or technical college experience preferred. Salary for Lecturers up to £1,500, for Laboratory Assistants up to £1,100, according to qualifications and experience. Two year contract, renewable, but this may be modified for an appointment on secondment Provident fund. Fares paid, also for family and for home leave every second year. Accommodation provided at 6 per cent of salary.

Write, quoting "N.4(57)," and enclosing stamped addressed foolscap envelope, to Director, Personnel Department, British Council, 65 Davies Street, London, W.1, for further particulars and application form, to be returned completed by November 8, 1957.

STATISTICIAN REQUIRED TO TAKE charge of the N.C.B.'s Hollerith Unit at London Headquarters The work is primarily of a research character and applicants should be competent to discuss statistical problems with users. Considerable experience in planning the operations, a knowledge of the potentialities of punched card equipment and a recognized qualification in mathematical statistics are required. Salary according to qualifications and experience within inclusive scales £1,271 to £1,764 male, £1,176 to £1,677 female Superannuation scheme, etc—Write for application form to Staff Dept. (X/945B). National Coal Board, Hobart House, London, S.W.1, before November 6, 1957.

CANTERBURY UNIVERSITY COLLEGE

CHRISTCHURCH, NEW ZEALAND

Applications are invited for the position of Senior Lecturer or Lecturer in the Department of Physics. The salary range for a Senior Lecturer is £1,315 per annum rising by annual increments to £1,615 per annum, and for a Lecturer £1,025 per annum, rising by annual increments to £1,275 per annum. An allowance is made towards travelling expenses.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. The closing date for the receipt of applications in New Zealand and London is October 31, 1957.

COVENTRY TECHNICAL COLLEGE

Applications invited for appointment as Lecturer in Inorganic Chemistry for higher national certificate and Grad R.I.C. courses. Candidates must have good technical qualifications and suitable industrial or service experience, previous teaching experience advantageous. For senior posts honours graduates or equivalent are needed Burnham Technical Scale salary, £1,200 by £30 to £1,350

Application forms and further particulars from Director of Education, New Council Offices, Coventry.

BRITISH IRON AND STEEL RESEARCH ASSOCIATION

Science Graduate required by the Association in their North-east Coast Laboratories (near Redcar), where novel methods for the preparation and smelting of iron ores are being investigated, together with improved techniques for sintering ore. Starting salary in the range £660 to £810 per annum, according to age, qualifications and experience. Post is superannuated under the F.S.S.U.

Written applications only, quoting "I.M.6," to the Personnel Officer, B.I.S.R.A., 11 Park Lane, London, W.1.

DIRECTOR OF FUEL AND PROCESS RESEARCH Department of Scientific and Industrial Research: The Civil Service Commissioners invite applications for this pensionable post at the new Research Station shortly to be built at Stevenage, in ultimate replacement of the present Fuel Research Station, Greenwich Age at least 30 on October 1, 1957. At the new Station the research programme will include (i) Work on problems of fuel and atmospheric pollution, which will include, but will not be confined to, certain projects to be transferred from the existing Fuel Research Station, Greenwich; (ii) some aspects of mineral processing; (iii) other projects (including projects involving process development) which can be appropriately undertaken with the staff and facilities to be provided. The staff (all grades) at the new station will initially number about 300 Candidates should preferably be physical scientists with a knowledge of the problems of chemical engineering. They must have high qualifications but a candidate without high formal qualifications may be considered All candidates must have had a wide experience in the organization and management of scientific research including research leading to and involving development to intermediate scale. They should also have had experience of administration and have the ability to lead and inspire staff over a wide field of science. The salary at Stevenage is £3,300 for a man per annum; for a woman it is at present somewhat less—Further particulars and application forms may be obtained from the Secretary, Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W 1, quoting S.4775/57 Completed application forms must be returned by November 22, 1957

CONTROL OFFICER REQUIRED BY Northern Nigeria Government Medical Department for one tour 12 to 24 months in first instance Salary scale (including inducement addition) £810 rising to £1,716 a year. Gratuity at rate £100/£150 a year Commencing salary according to experience Clothing and touring equipment allowance £85 Free passages for officer and wife Assistance towards children's passages and grant up to £288 annually. Liberal leave on full salary. Candidates, preferably single, should have good general education and agricultural training or knowledge of surveying, mapping, entomology or botany.—Write to the Crown Agents, 4 Millbank, London, S W.1 State age, name in block letters, full qualifications and experience and quote M3A/43728/NF

PRECISION B S INSTRUMENTS

Refractometers for Industry and Research

Our well-known standard Abbe type refractometer has a refractive index scale on glass and is read by transmitted light, thus leading to greater convenience in taking measurements and a higher degree of accuracy.

The instrument as illustrated is supplied with degree scale arc and micrometer screw reading directly to 10 seconds, corresponding to a refractive index accuracy within 0.00005. Conversion tables for use with sodium light are supplied.

Full particulars sent on application.

We shall be pleased to demonstrate these instruments and give any advice within our power, if you will call at our Works

SIGNIFICANCE OF UNIVERSITY TRAINING IN INDUSTRY

FOR the past three years Political and Economic Planning has been engaged on an inquiry into the employment of graduates in industry, and this study, which has been sponsored by the Joint Committee on Human Relations of the Department of Scientific and Industrial Research and the Medical Research Council, assisted by a grant under the Conditional Aid Scheme for the Use of Counterpart Funds derived from United States Economic Aid, resulted last autumn in a report entitled "Graduate Employment". In that report, nearly four thousand replies to a questionnaire sent to men who took a first degree in arts, science or technology at a university or through a university college in the academic year 1949–50 were analysed. This sample survey traced the careers of these men for the first few years and threw some light on the factors determining their choice of career. The inquiry, however, also visualized a survey of the views of the universities on the whole question of education for industry, and a third survey, of the views of industry on this question and into the developments that are taking place in industry in the recruitment and employment of university men and women.

A report has now been issued on this third aspect*, which was governed by the following terms of reference approved by the Department of Scientific and Industrial Research, for which the inquiry was made: "To investigate the policy and practice of British industrial undertakings in respect of the recruitment, training and employment of university graduates".

The report is concerned with a sample only of the graduates covered by the first inquiry—some 594 of the graduates and 47 out of the 700 industrial firms, to which four area gas boards, as representing the nationalized industries, were added; and of these graduates, 517 were still in industry when they were interviewed. About a fifth of them went into the chemical and allied industries, and nearly a quarter into electrical engineering: 9 per cent went into firms manufacturing metal or metal goods, and another 9 per cent into firms producing consumer goods in the widest sense. Some 60 per cent of the men were still with the firm about which they were interviewed.

The general impression left by the survey is of the empirical approach made both by employers and by graduates to the whole question of university men in industry; but that nevertheless, on the whole, both managers and graduates were satisfied with the use made of graduates' abilities. Neither the graduates, nor their employers, thought of themselves as a class apart, nor were they so employed. Once a graduate had joined a firm, he was considered primarily as an individual, treated on his merits and had to make his way alongside others who had not gone to a university. At each stage from recruitment onwards, firms tended to adopt such measures as seemed most fitted to their needs and to adjust them in the light of experience, and the results, if informal rather than formal, were none the less deliberate and level-headed. Only at the stage of recruitment did it appear that shortage of supply of qualified man-power was leading to the adoption of measures out of proportion to the results achieved.

It is at this point that the report makes its strongest criticism of existing practice, while emphasizing the extreme importance of an effective partnership between industry and the universities; but it finds a good augury for further advance in the adaptability which has marked industry's relations with the universities since the War. Since the survey was made, the system under which firms send at their own expense acceptable candidates from their staff to universities has developed greatly, but P E P suggests that the possible effects of this policy on recruitment merit consideration. Elsewhere, P E P comments that the form taken by recruitment campaigns should be a matter of much concern, since they affect university teaching staff as well as students. To say the least, the continual invasion of university life by those seeking to recruit scientists and technologists is disturbing, and the universities' new programme of expansion, which will provide more graduate scientists and technologists, will contribute to the long-term solution. In the short term, however, P E P suggests that the larger firms conducting these recruitment campaigns and setting the pace might consider whether there is anything they could do to mitigate their impact on university life.

This is only one aspect of the relations between the universities and industry on which some stress is laid. Forty-three of the undertakings had a deliberate policy of recruiting graduates, and almost all these had some graduate scientists or technologists on their staff and gave as a reason for recruiting them that they needed the knowledge the graduates had acquired. Only half gave as a reason their value as potential managers. Fewer firms recruited arts graduates, and only a third of these recruited them with the possibility in mind of their eventual promotion to management. Again, much emphasis was laid on the importance of personal qualities, especially the ability to get on with, and eventually to lead, others. Sometimes there was aversion to brilliance or a first-class honours degree, and when the desired personal qualities were not found in the graduates eventually recruited, this was occasionally attributed to the lack of residential accommodation at the universities.

---

* Graduates in Industry. Pp. xxii+261. (London: Political and Economic Planning; and George Allen and Unwin, Ltd., 1957.) 30s.

Broadly, the numbers of university graduates on the strength, the academic standard sought in recruitment and the regularity of the steps taken to assess need, ran with the size of the firm; but it is obvious that this requirement bears closely on the character of the education and the facilities to be provided at the universities. Even if industry takes appropriate steps, as P E P suggests, to ensure that the best-qualified recruits are used to the full extent of their capacities in the initial stages of their careers, and carefully grades the work on which graduates and non-graduates are set, the reconciliation of the conflict between industry's specialized interests in certain fields of knowledge, and the traditional functions of a university as a seat of learning for its own sake and in all its disciplines, is not simple. Although a little more than half the members of management thought that universities should do more to meet the needs of industry, a third thought they could do no more; nor did the views expressed amount to any serious challenge to the policy of the universities. Some members of management stated explicitly, and more implied, that it was for the universities and not for industry to set the pace.

Nevertheless, even if the influence is indirect rather than direct, the steadily rising proportion of university students in receipt of assistance from public funds in one way or other means that the universities must be increasingly concerned to supply graduates with the qualities sought by their prospective employers; nor can we assume that the balance of studies is unchangeable. It should be noted that, while half the members of management believed that a university education had advantages for industry over a technical college education, a large proportion were non-committal. There was, however, a great measure of acceptance of the principle that the universities should not be asked to cater in first-degree courses for the specialized interests of particular industries, and some indication of a trend of opinion in favour of making the established first-degree courses in science and technology more fundamental, reserving any specialization for post-university courses, and of leaving to industry itself the responsibility for seeing that the knowledge acquired at the university is fruitfully applied.

The views were subject to reservations as to the need for closer contacts with industry by university teaching staff and for the acquisition of greater knowledge of industry by undergraduates heading for it; and vacation work was largely favoured for this purpose. There is a substantial body of university opinion against vacation work as such, and P E P suggests that an inquiry concerned primarily with vacation work as a means of preparing undergraduates for a career in industry might be well worth while. There was little evidence of support from the management side for the sandwich system so far as the universities are concerned, and the academic year in Britain does not lend itself very readily to this system.

The further provision made for the study of industrial management at certain universities since the time of the survey meets to some extent the call for such courses made from the management side. Although there are indications that university teaching staff are inclining to the view that a management discipline, if evolved, would not be incompatible with the true function of a university, even when the survey was made the general consensus of opinion appeared to be that the greater part, at least, of such study should be reserved for the post-university stage, when the student is more mature and freer to concentrate on it. Since then, the trend of thought has been in favour of reserving the subject until the graduate has had enough industrial experience to profit by study of it—until he is at least about twenty-seven years old. The stress which has been laid upon efficiency in management by the developments loosely described as automation and the emphasis given to human relations in industry all point in the same direction.

An important aspect of the expansion of technological education on which the survey throws some light is the proportion of men with academic qualifications beyond the first degree who are needed. Admittedly, the value of a higher degree to a firm must depend largely on the standard and the level of scientific and technological work undertaken, and not only in research departments; but nevertheless, it is noteworthy that only a third of the members of management questioned saw any value in a higher degree and few of these were emphatic. Political and Economic Planning thinks it possible that the new arrangements for centralizing in the Department of Scientific and Industrial Research awards of research studentships in science and technology may eventually meet some of the criticisms made of the usefulness of higher degrees. In particular, the new advanced course studentship awards in "a specialized subject, a training in which is expected to add substantially to the value of the degree already taken", will meet the wish expressed by some managements for graduates to receive specialized training in the branch of science or technology in which the firm was interested, after a broad first-degree course.

Apart from these questions of shortage of supply, the picture presented by the survey shows a substantial measure of agreement with the new partnership with the universities. While there was some indication of greater readiness on the part of industry to accept responsibility for seeing that the knowledge acquired at the university by its recruits is fruitfully applied, there is plenty of evidence that with closer co-operation and increase in mutual understanding many useful suggestions will come from industry as to the content of courses, and especially in regard to the form and phasing of post-university study and the proportions in which men—and women—of any given standard are required. P E P wisely points out that increasing attention must be given to the whole question of the proportion of each grade needed in any particular circumstances, from the lowest qualified technician to the most highly qualified technologist.

This question is basic to the planning of the expansion of technical and technological education in Great Britain; but it has so far been virtually ignored. Unless that expansion is planned in relation to ascertained needs, we cannot well avoid waste of the large sums of money now committed, and it is essential that there should be no interruptions to the building programmes at present authorized for the colleges of technology, technical colleges or the universities, except in accordance with definitely determined needs. In its default, we are likely to see once again expansion postponed for short-sighted and illusory reasons of economy.

Nor is this the only point at which the survey touches on the question of husbanding our resources. Selection techniques are only in their infancy, and while selection was generally in the hands of people with wide experience of selection or with direct knowledge of the field in which the candidate might be going to work, more efficient selection could obviously help to reduce the loss from industry to other walks of life of an eighth of the men it recruited from the 1950 graduation year. A certain amount of mobility between jobs is desirable as the best means of widening experience, and in some fields such as research could stimulate creative work. Nevertheless, the actual turnover appears to be higher than is really necessary, and while, on one hand, it is related to the accuracy with which a firm assesses its needs for graduates, on the other it depends both on the skill with which selection is made and the treatment, including training, which the recruit receives.

In regard to the first, the survey emphasizes the importance of industry continually re-examining and assessing what kinds of graduates it really wants, and in what numbers, especially in view of changes hoped for in the proportion of students reading for an arts degree or for a science degree, and of the major developments in train for the expansion of technological education. Industry claimed 30 per cent of those graduating in 1950, and it is unlikely that, except possibly in university teaching, the demand for graduates from other quarters will increase proportionately as much as that of industry. P E P points out very firmly that improved methods of selection, the better matching of men to work and the more efficient grading of work and assessment of performance in it all contribute to sharper definition of industry's demands on the universities, while qualitatively industry should be thinking out the implications of the argument that the non-scientist and the scientist, in whatever walk of life, must be enabled to appreciate each other's methods and approaches, and formulating proposals for measures which the universities might take to that end.

In regard to the second, it is suggested that problems encountered in introducing graduate recruits to a firm and in training them might be overcome if some well-chosen senior member of the staff established and maintained a close and friendly relation with each new entrant. Employers might be able to judge more accurately the real calibre of the newcomer and become more quickly aware of any frustrations and misunderstandings. They might also be better able to reduce the rather high rate of dissatisfaction with prospects of pay and promotion, which was closely related to the turnover, in itself a source of waste of man-power. It also seems reasonable to expect that, as P E P remarks, the appointment of a senior to establish and maintain a close relation with arts graduate recruits might also contribute towards further developments in the ways in which they might be employed, and generally in making the initial period in the firm more rewarding or at least more explicable. Further, the survey notes that arts graduates were the least satisfied with their first job, and science graduates the most satisfied; and it would appear probable that such a senior appointment could well help to probe the genuineness of dissatisfaction, to remove it where genuine, either by dissipating misunderstanding or by representing to the management a point of view that policy had overlooked or ignored. Incidentally, if the volume of unjustified dissatisfaction or disgruntlement proved to be large or excessive, some clues might be obtained which the universities could follow with the view of modifying their courses. Both industry and the universities should be helped by this survey, which, while once again pointing to the need and value of further continuous study in this field, emphasizes the importance and urgency of various developments now in train, and indicates directions in which further inquiry and some strenuous thinking are imperative by industry, by the universities and by the Government.

THOMIST PHILOSOPHY

The Christian Philosophy of St. Thomas Aquinas
By Etienne Gilson. With a catalogue of St. Thomas's Works by I. T. Eschmann, *O.P.* Translated by L. K. Shook, *C.S.B.* Pp. x+502. (London: Victor Gollancz, Ltd., 1957.) 42*s.* net.

ETIENNE GILSON'S massive study of the philosophy of Thomas Aquinas is now available in English and we are indebted to his translator for a faithful and reasonably clear version of this important work. No translation which was accurate could make it easy reading, and probably only those who share M. Gilson's conviction that Thomism is a system of thought in its main outlines valid to-day will have the determination to persevere to the end. Gilson himself has no doubt on this matter. He holds that "the basic metaphysical positions of Thomas Aquinas are still far ahead of what is considered most progressive in the philosophical thought of our own times". He claims that Thomism is not only an interesting phase in the history of philosophy, but also a "live option" for contemporary reflexion. 'I do not say of Thomas that he was right, but that he *is* right.'*

Gilson has organized his material in three sections: 'God', 'Nature' and 'Morality', a plan which enables the reader to gain a comprehensive view of the system and to recognize the astonishing range and the coherent structure of St. Thomas's thought. The value of the book is enhanced by the full notes and references provided by the author and by the catalogue of St. Thomas's writings contributed by I. T. Eschmann. It is possible in a short review to comment only on a few points of interest in this extensive study. Anyone unacquainted with the vast literature of interpretation which has grown up may be surprised to learn that there are fundamental differences among experts about the proper approach to the Thomist philosophy. Gilson's view may be described as, in a sense, 'existentialist'. In his opinion, the conception of 'act of being' is central for any true understanding of the philosophy and he deplores the prevalence of an 'essentialist' interpretation in the Roman Catholic Church. The layman may have some difficulty in grasping the significance of this distinction, but the effort is worth making, because the matter in dispute really does go to the root of the question of what Thomas conceives reality to be.

The chapter on the famous 'Five Ways' by which the intellect moves towards the affirmation 'God exists' will no doubt attract the attention of most readers and it is among the best in the book. Gilson brings out the logical character of the proofs with admirable clarity. "All the Thomistic proofs for the existence of God amount, in the last analysis, to a search, beyond existences which are not self-sufficient, for an existence which is self-sufficient and which, because it is so, can be the first cause of all others." Excellently put—but we are not told how a 'search' becomes a 'proof'. It is worth while, perhaps, noting that Gilson, following Thomas, quotes as a guiding principle the famous phrase in Exodus, "I am that I am", and takes it to indicate eternal and immutable being. Surely it is time that some interpreter of Thomism should deal with the objection that the Hebrew probably means, "I will be what I will be"—a sentence which suggests a very different idea. Of course, this has no relevance to the validity of Thomas's metaphysics as such, but it does have some bearing on the question whether his doctrine of God is, as is asserted, the crown of a definitely Christian philosophy. Gilson's book is a fine example of patient scholarship and thinking and, moreover, a worthy tribute to a great philosopher.

W. R. MATTHEWS

THE PRIMATES

Primates

Comparative Anatomy and Taxonomy. By W. C. Osman Hill. 3: Pithecoidea. Platyrrhini (Families Hapalidae and Callimiconidae). Pp. xix + 354 + 27 plates. (Edinburgh: At the University Press, 1957. Distributed by Thomas Nelson and Sons, Ltd.) 90s. net.

IN the third of his monographs on the primates, Dr. W. C. Osman Hill continues his labour of drawing together what is known about the comparative anatomy and taxonomy of the mammalian order to which man belongs. The present volume deals with the family Hapalidae (= Callithricidae) of the New World monkeys, and follows the pattern of the two by which it was preceded, the merits and shortcomings of which it also shares. Dr. Hill's aim, which is to provide an authoritative and up-to-date account of the marmosets and tamarins, is an ambitious one, and he deserves great praise for giving us once again a book which students of the subject will find both convenient and wise to consult. Presumably because encyclopædic works have a habit of not being written, or if started, not being finished, Dr. Hill has made the completion of his task a goal in its own right. But haste has taken an inevitable toll in scholarship and detachment.

According to Gaylord Simpson's classification, the New World monkeys comprise the superfamily Ceboidea, consisting of the family Cebidae, itself broken down into a number of sub-families, and the family Callithricidae, with the latter of which Dr. Hill is concerned in the present volume. Dr. Hill gives no sound reason for departing from the taxonomic rules, the existence of which he acknowledges, when he refers to the Callithricidae as the Hapalidae. The title page and text also refer to, and deal with, a so-called family Callimiconidae. This family consists of the one genus *Callimico*, with a single species constituted by a small tamarin-like creature from the Upper Amazon. It seems that this species is known from no more than perhaps a dozen specimens that have lived in zoos.

The late Oldfield Thomas, of the British Museum, regarded *Callimico* as a taxonomic sub-family of the Cebidae, because of the correspondence of its dental formula to that of the capuchin monkeys—a view that is now endorsed by Gaylord Simpson. A little later Pocock took the line that the tamarin-like feet and hands of *Callimico* argued that the creature should be designated as a sub-family of the Hapalidae (= Callithricidae). Then Dollman "took the bolder step of raising *Callimico* to the rank of a distinct Family intermediate between the Hapalidae and Cebidae". It is this bolder step which Dr. Hill, again without giving any reasons for his preference, follows.

In the preface, however, Dr. Hill apologizes for doing this. Too late to allow of any alterations in his title-page or text, an opportunity was provided him for studying a specimen of *Callimico*. As a result of this increase in his knowledge, he decided that *Callimico* does not represent a family of its own, but really belongs to the tamarins.

There is, perhaps, something almost too arbitrary in this treatment of familial distinctions in primate taxonomy. The prominence of the slip inevitably draws one's attention to the apparently casual way in which Dr. Hill treats different schemes of classification; and to the difficulty of deciding which parts of his descriptions are derived from which sources.

Unfortunately there are other places where he has not exercised his critical faculty to the full. He states, for example, that "in a broad way . . . there is an ascending grade of complexity in behavioural mechanisms from the marmosets up through monkeys and anthropoid apes to the human level"—when such evidence as there is points to little or no gradation in definable behavioural characteristics as between monkeys as a group and apes as a group. He tells us that "vocalization" in many instances deserves the name of "veritable language", but the name of the one 'authority' he cites does not leave the reader with the confident feeling that Dr. Hill has consulted any serious studies on the subject of language. He writes that "menstruation has not been shown to occur in any platyrrhine", which is contrary to fact; and to give another example, he talks of "lethal factors" in a genetic content, in a way which suggests that he does not realize how much biometrical study needs to be undertaken before such things can be posited.

But having said all this, the fact remains that, in spite of these faults, the book contains a mass of good meat. Its very presence and massiveness will ensure it, as the same qualities will their predecessors, a useful life.

ELECTRICAL SCIENCE

Introduction to Electrical Applied Physics

By Prof. N. F. Astbury. Pp. xi+241. (London: Chapman and Hall, Ltd., 1956.) 36s. net.

As the author says in the preface to his book, it is an attempt to bring together the classical bases of electrical science and the elements of some specialist topics which, by the natural processes of technological evolution, are finding their way into all fields of applied science.

The method of presentation used throughout the book is to deal first with the fundamental physical and theoretical principles of each topic and then to apply them to the consideration of practical problems. Special mathematical tools such as space vectors, Bessel functions and Heaviside's operational analysis are treated with their applications, rather than abstractly and in a separate part of the book. This feature will be particularly welcomed by the reader with a practical rather than an analytical turn of mind. Consequently, each chapter is almost self-contained and the necessity for cross-referencing is much reduced. But where it is still needed, the task might have been simplified by the simple expedient of marking the chapter and section numbers on each page.

The book begins with a consideration of the physical basis of the subject, introducing the concepts of the quantum theory when dealing with electric conduction in solids, treating the origin of magnetism from the point of view of the domain theory, and briefly outlining the behaviour of dielectrics in terms of polar and non-polar molecules. Electric and magnetic fields are treated on classical lines. In a chapter on electrical units and the general field equations, a sound case is made for using a rational system of units which gives the general equations a homogeneous form; the rationalized M.K.S. system is used throughout the book. An examination of the field equations when conduction current is present leads to expressions for the penetration of flux, and for the eddy-current loss, in flat sheets and circular cylinders, and for the skin effect in cylindrical conductors; Bessel functions are introduced to the reader unfamiliar with them as the solutions to familiar problems.

The chapter on electric circuits deals with lines, filters and general methods of circuit analysis including the use of the Laplace transform. (The use of the lower case symbol i for the electric current vector in equations such as $V/i = R + jX$ should be altered in a reprint of the book.)

Gapped magnetic circuits, including permanent magnets, the equivalent circuit of an iron-cored coil system, distortion and the magnetic amplifier, are treated in an excellent chapter on magnetic circuits. As in other parts of the book, the author has succeeded in presenting the basic physical facts and principles so that they seem to lead naturally to important practical applications.

In connexion with electro-mechanical and electro-acoustical systems, limitations of sensitivity due to noise are considered, and a brief introduction is given to the study of servo-mechanisms. The chapter on electron devices deals with the deflexion of electron beams, thermionic valves and valve amplifiers, transistors and photosensitive devices. The final chapter deals with electro-magnetic waves and radiation, including a study of transmission through the ionosphere and an introduction to the theory of wave guides.

As the author modestly observes in the preface, "the subject of every chapter in this book forms, elsewhere, the subject of a separate treatise", and those recommended by the author are listed in the book. Unfortunately, no other references are given.

The work is intended for the senior university student in physics or engineering, but it should also appeal to others seeking an understanding of the principles underlying many recent technological developments. It is easy to read, well produced and reasonably priced. H. Kayser

NUMERICAL METHODS

Numerical Methods

By Dr. R. A. Buckingham. Pp. xii+597. (London: Sir Isaac Pitman and Sons, Ltd., 1957.) 70s. net.

In recent years a number of books on numerical analysis have been brought before the scientific public, and these vary in their objectives from educational didactics to automatic digital calculators, and in their style from lucidity to the pomposity which besets certain authors when they come to expound their so-called 'philosophy'. Dr. R. A. Buckingham's book is the latest work on the subject to come before the reviewer and, although the publishers' lists seem to give promise of more such works in the future, it will be difficult for authors to find new ground to cover, at least on the general plane.

To the last statement certain limited qualifications are necessary. Two omissions from his book are mentioned by Dr. R. A. Buckingham in his preface: namely, discussion of Gaussian methods of quadrature and of the Runge–Kutta formulæ for the solution of differential equations. It is a little difficult to accept the author's excuse that these omissions are justified by the presence of an adequate literature in the field, because this applies to much that he does include. A further omission, which is rather more difficult to understand, is that of an up-to-date discussion of throwback, particularly in view of the author's plea that the book is intended for hand computers. On a minor plane, I regret the absence of an account of vector-space methods for the solution of simultaneous equations, linear and otherwise.

These criticisms are, however, ones of detail and should not detract from the overall good impression which the contents of the book produce. The treatment is to some extent classical. Thus, the first five chapters discuss errors, tables and desk machines;

the various forms of differences; Lagrangian interpolation, differentiation and integration; and Newtonian divided differences and their consequences respectively: curiously, operational methods are relegated to Chapter 6 as though by afterthought.

The next two chapters contain a good summary of the methods which can be used to solve one-point boundary-value ordinary differential equations, and these are followed by Chapter 9 on polynomial equations and Chapter 10 on curve fitting by the methods of least squares. Simultaneous linear equations, matrices and the relaxation method then receive a chapter each, and these lead to Chapter 14 on two-point boundary-value problems, latent roots, and integral equations. Finally, there are two chapters, on two-dimensional interpolation and on partial differential equations respectively, and the book ends with four appendixes containing formulæ.

The book is lavishly provided with worked examples which will be useful to student and teacher alike, and the only place where detail is, perhaps, insufficient is in the section on the relaxation method. Only the high price will prevent the book from adorning the shelves of all serious numerical analysts, and this must be weighed against its considerable size. I end on a note of criticism of the publishers: the format is (to quote a colleague) "execrable" and the narrow margins surely cannot be justified on any grounds of paper economy at the present time.

A. D. Booth

COMMONWEALTH INDUSTRIAL CONFERENCE

His Royal Highness the Duke of Edinburgh's Study Conference on the Human Problems of Industrial Communities Within the Commonwealth and Empire, Oxford, 9–27 July, 1956

Vol. 1: Report and Proceedings. Pp. xii+338+7 plates. Vol. 2: Background Papers; Appendixes; and Index. Pp. xv+339. (London and New York: Oxford University Press, 1957.) 42*s*. net the set of two volumes.

THESE two volumes constitute a complete record of the proceedings of the Conference (see *Nature*, 178, 341; 1956). Their principal contents are the addresses given at the Conference, the reports of the study groups into which the Conference membership was divided, each of which spent a week studying particular problems in one of the main industrial areas of Britain, and the background papers which were distributed to members to stimulate thought on some of the more important issues.

The background papers are, from a reader's point of view, the most valuable element. They provide a fairly comprehensive and often stimulating introduction to the problems of particular territories, ranging from Australasia through Malaya, India, East and West Africa to Britain itself; the remaining nine are more general and include contributions on political life (by Sir Ivor Jennings), the will to work (Prof. C. A. Mace), and values in an industrial society (Prof. D. W. Harding). The sixteen addresses given at the Conference, mainly by industrialists and trade unionists, are of a fairly general nature, and cover such topics as industrial structure, developments in management, work motivations, industry and the community, and the multi-racial society. They are useful, but do not always reach the high standard set by many of the background papers.

Considered as a contribution to knowledge, the two volumes provide little that is new to the professional social scientist, nor perhaps is this to be expected in a conference concerned primarily with practical problems. It is, however, legitimate to ask whether existing knowledge has been brought to bear to the fullest extent. Prince Philip, in his presidential address, urged the participants to take into account the "great amount of work already done", and Sir John Maud in his address particularly mentioned the indispensable contribution of the social scientist. Despite these exhortations, it is difficult to avoid the conclusion that the organizers were not particularly successful in making this contribution available to the Conference. So far as one can see, not a single professional social scientist addressed the Conference, although a number of background papers were contributed by sociologists. It would not be difficult to list several recent researches, and in particular those sponsored by the Joint Department of Scientific and Industrial Research and Medical Research Council Committee on Human Relations, which are directly relevant to the problems discussed but which were apparently passed over.

What impact will the Conference have made? Prince Philip was again realistic when he commented that it could only scratch the surface, and Sir Philip Morris in his summing up urged the members to recognize that study in a conference is necessarily practical and superficial, and that its full fruit could be ripened only by continual effort. Will it so ripen? It is difficult to avoid pessimism. Conferences all too frequently have a stimulating but transient effect on busy practitioners. Experience suggests that rapid progress in any field demands two conditions—the systematic study of problems, and an effective link between students and practitioners. The Conference fruits will ripen only if social research into industrial problems is steadily extended, and if practitioners have regular opportunities to study developing knowledge and ideas. Indeed, the best sequel to the Conference would be an extension of present arrangements for practitioners both in Britain and overseas to spend, preferably in small groups, a period of study leave at one or other of the few universities in Britain which are so far equipped to receive them.

W. H. Scott

MODEL BUILDING FOR ECONOMISTS

Mathematical Economics

By Prof. R. G. D. Allen. Pp. xvi+768. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1956.) 63*s*. net.

ECONOMISTS, in their interpretation of the present, mainly rely on the historical approach and on reasoning by analogy with the past; but this frequently involves considering the interplay of several influences. As a means of avoiding false reasoning and of simplifying and shortening logical arguments, economists have made increasing use of the abstract 'model'. This model represents the real situation in an ideal State, with most of the complications assumed to be absent, so that attention can be focused on the interplay of what are supposed to be the most important influences. The models obey exact mathematical laws and the art of building them requires some mathematical expertise. Many economists know enough of one branch of mathematics to build some imposing models: few know enough to understand the models built by the others. Prof. R. G. D. Allen's book should help to spread the mutual understanding.

Mathematical economics or model-building is, however, still mainly the subject either of specialist periodicals devoted to it as to a hobby such as chess, or, more usefully, of appendixes and footnotes in more serious works which really are about economics. It here serves to clear up knotty logical points, cropping up in the course of discussing practical questions, in terms of political arithmetic and history. Unless he remembers this subsidiary part played by mathematical economics in economics proper, any reader coming fresh to this book from a study of mathematics or science will be in danger of forming a very distorted impression of what economics is about.

This book confines itself to a limited but representative selection of types of economic model, each of which has been created in response to the genuine needs and interests of *bona fide* economists. The author shows how the same few basic mathematical techniques appear over and over again in widely different fields of application: and he provides a series of lucid mathematical chapters, giving the basic training in these selected mathematical techniques. Their level is sufficiently advanced for it to be doubtful whether, apart from Prof. Allen himself, any reputable English economist could claim that he had already mastered much more than half of them. The mathematical chapters in this book are written in a style very well suited to the requirements of those who would care to master more.

By denying himself any treatment of questions relating to probability or random variates, the author allows himself a fuller treatment of other topics. He gives considerable emphasis to the application of linear differential equations and difference equations to the study of models reproducing trade-cycle phenomena. Such methods are useful only to models yielding oscillatory movements in the variables concerned: they are usually inadequate to analyse models which yield two alternating positions of temporary stable equilibrium, boom and slump: accordingly such non-linear models are given only very brief mention: yet it may be that they are of more relevance to the world we live in. This suggests one unavoidable handicap imposed by the method of selection of subject-matter according to its mathematical content: namely, that the more mathematically awkward subjects tend to be omitted.

Linear programming and von Neumann's theory of two-person games receive liberal attention: these are of relevance in situations where one knows exactly what one wants and how much, and the extent of the resources that are available for obtaining it. This is the branch of economics devoted to war and siege, but it also has applications to the operations of the very large business unit and of planning committees. The calculation of optimum programmes is in practice very tedious, but the increasing availability of electronic calculators will reduce the importance of this consideration.

Vector and matrix algebra also receive full treatment. These, for example, enable the economist to extend his arguments from the representative man consuming *the* consumption-good produced by industry, to deal with families of varying composition and income consuming a series of consumption-goods and services provided by a list of industries and caterers.

This book should be compulsory reading for all economists seeking to publish articles involving economic models. D. G. CHAMPERNOWNE

PACIFIC OCEANOGRAPHY

Oceanic Observations of the Pacific, 1949

Edited by N. W. Rakestraw, Paul L. Horrer and Warren S. Wooster. Pp. 363. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1957.) 34*s*. net.

THE usefulness of oceanographical data is increased by early publication, but getting them prepared for publication is not easy. The purpose of the observations is often exciting and rewarding, and everyone gets on with it, and probably uses only a selection of the data. The task of checking thermometer corrections, salinity figures, density calculations, and other computations for all the data, for other uses and for others to use, is an urgent duty which is often neglected owing to the claims of direct interpretation and the need of making more observations; there are also the costs of publication and distribution.

The Scripps Institution of Oceanography of the University of California has done marine science a good service by making provision for regular publication of physical and chemical data from the Pacific Ocean. The first volume collects observations made by the Scripps Institution, the Department of Oceanography of the University of Washington, the U.S. Navy Electronics Laboratory and the Pacific Oceanic Fishery Investigations of the U.S. Fish and Wildlife Service, and offers to publish the data of other agencies which work in the Pacific Ocean. It is a handsome well-bound photoprinted book. The first of a series, it contains observations made in 1949 hitherto unpublished, together with charts showing when they were made and a list of published papers referring to the 1949 cruises and to results already obtained from them. The observations cover the ocean north of the equator as far west as Hawaii, and there are closely spaced, repeated, measurements extending four hundred miles off shore between 46° and 25° N. There are not many observations from depths greater than 1,200 m. The remainder of the ocean, and some of the Indian Ocean, are covered by bathythermograph observations, and there are so many thousands that it is not practical to publish them either as photographs or in lists. The numbers available in each 5-degree square are shown in the charts, and copies of the slides are deposited at the Scripps Institution.

Subsequent volumes containing observations made in each succeeding year will be published as soon as they are ready, and there will also be one for observations made prior to 1949 together with a bibliography of earlier sources.

The editorial board at the Scripps Institution, its consultants in the agencies participating in the scheme, and the publishers are to be congratulated on a fine achievement. G. E. R. DEACON

Outline of Glossematics

A Study in the Methodology of the Humanities with Special Reference to Linguistics. Part 1: General Theory. By H. J. Uldall. (Travaux du Cercle Linguistique de Copenhague, Vol. 10 (1).) Pp. vi+90. (Copenhague: Nordisk Sprog- og Kulturforlag, 1957.) n.p.

THE subject of this book is not, as the title might lead one to suppose, a branch of linguistics; the author is inaugurating a new science, glossematic algebra, which shall be a formal non-quantitative technique of description in 'humanistic' disciplines such as linguistics and history. Pages 1–35 are occupied by general remarks on scientific method, like these: "the pragmatical scientists, never having found anything in a pure state of being, refuse to have anything to do with it" (p. 9); "Any post may bring the scientist news that . . . nothing, or very little, remains of the truths of yesterday" (p. 13). In the formal development of glossematic algebra that follows, the author begins by defining 'function' as "any dependence" and 'functive' as "anything that enters into a function"; the discussion (pp. 36–41) is made hard to follow by the use of a single symbol φ (without subscripts) even in symbolizing situations that involve several functions. He next introduces a specific function, 'connexion' ('both–and'), which is commutative and associative; non-commutative algebras, we learn, are "extremely difficult" to design, and so devices for symbolizing the difference between the words 'fist' and 'fits' are postponed to the next instalment of this work. The next important concept is 'glossematic negation'; the author wishes to show symbolically that, for example, the phoneme which might, but does not, precede the [l] of "lay" is [p], rather than [s] or [k]. The rest of this fascicule is an elaborate set of formal schemata for descriptions, in terms of connexion and negation; some concrete examples are supplied, but these do not carry conviction that glossematic algebra is likely to be a fruitful study.

P. T. GEACH

Lecture Experiments in Chemistry

By G. Fowles. Fourth, revised edition. Pp. xvi+629. (London: G. Bell and Sons, Ltd., 1957.) 42s. net.

THE author has added a number of new and interesting experiments to the fourth edition of this book. Thus, on the movement of molecules, the different rates at which hydrogen chloride and ammonia diffuse is illustrated by Prof. Watt's experiment of placing cotton-wool swabs, soaked in hydrochloric acid and aqueous ammonia respectively, at either end of a long tube, and noting the position at which a white ring first forms inside the tube. Similarly, the Brownian movement is demonstrated by a novel experiment using colloidal graphite. The major change in this edition is the recasting of Chapter 6 on physical principles, and the insertion of three new chapters on, respectively, surface chemistry, catalysis and combustion. The intensive study of colloids and adsorption, and their industrial applications, have introduced new processes and products into daily life, and this has enabled the author to describe a number of new experiments. Thus six pages are devoted to the use of ion-exchange resins, and the teacher will find the experiments with coloured ions of particular interest. In view of the size and scope of the book it is, however, a little disappointing to find only one experiment on paper chromatography. Small additions have been made to the appendixes and supplement at the end of the book; these include a short account of recent views on the teaching of chemistry, a few experiments, and further notes on some of the experiments previously described. Like its predecessors, this edition is a mine of useful information, and the revision has been well done apart from a few minor details, such as the descriptions of the mechanisms of the electrolysis of brine (p. 432) and the ferric sulphocyanide reaction (p. 413). The book is well produced and deserves the warm welcome which the other editions have received.

A. C. CAVELL

A Text Book of Theoretical and Inorganic Chemistry

By F. A. Philbrick and Dr. E. J. Holmyard. New revised edition by Dr. E. J. Holmyard and Dr. W. G. Palmer. Pp. ix+845. (London: J. M. Dent and Sons, Ltd., 1956.) 18s. 6d.

WHEN Dr. Palmer, of the University of Cambridge, was called in as collaborator to help with the production of the 1949 edition of this book, he revised the whole physical chemistry section forming Part 2. He also re-wrote the section on valency, making of it a first-class self-contained article. In preparing the present edition, for which he alone is responsible, Dr. Palmer has thoroughly overhauled the descriptive matter forming Part 3. He has replaced discarded explanations by modern ones; described new reagents, such as lithium aluminium hydride, thereby introducing better methods of preparing diborane and silane; described the use of deuterium and radioactive tracers in the elucidation of molecular structures; here and there deleted or added a few lines, occasionally recasting whole paragraphs. All the changes have been made so skilfully that the pagination is unchanged. There are few text-books of intermediate level combining in one volume both general and descriptive chemistry. Many will be pleased that one of the best of the few has once more been brought up to date.

G. FOWLES

The World of Learning, 1957

Eighth edition. Pp. xxxii+1038. (London: Europa Publications, Ltd., 1957.) 120s. net.

"THERE is little room for ornament or artifice in a work of reference. It relies for its effect on the austere beauty of facts." Thus claim the editors of this book. It is doubtful whether there is another volume with so much austere beauty between its covers. "The World of Learning", which has run to eight editions in ten years, lists the academies, learned societies, museums, universities, art galleries and libraries of the whole world, together with their professors, members, curators, presidents and secretaries. One can look up the number of books in the library of the Université d'Haiti or the date of foundation of the West African Cocoa Research Institute. There are a list of publications issued by each institution and a big section on Unesco. Unfortunately, owing to its size, this book omits an index of names—it is possible to look under the University of *X* and find Dr. *Y. Z.* works there, but not to look up Dr. *Y. Z.* in order to find where he does work. Nevertheless, there are few other books with so much readily available, useful and up-to-date information about the world of learning.

RADIO OBSERVATIONS OF THE RUSSIAN EARTH SATELLITE

By THE STAFF OF THE MULLARD RADIO ASTRONOMY OBSERVATORY, CAMBRIDGE

History

WHEN the news of the launching of the first Earth satellite was received early on October 5 it was realized that accurate optical or radar observations would be extremely difficult unless reasonably accurate local predictions of the track could be obtained from observations of the radio transmissions from the satellite. No plans for such radio observations were known to us, and we therefore decided to modify an existing radio telescope normally used for the study of radio stars on a frequency of 38 Mc./s.

The first recordings were obtained on the night of October 5–6, and on the following day an improved interferometric aerial system was installed so that the transits of the satellite across the Cambridge meridian could be timed more accurately. A second receiver was also installed to measure the Doppler frequency change. Both instruments were tuned to the 40 Mc./s. transmission to reduce errors caused by ionospheric effects. Similar measurements were afterwards made on the 20 Mc./s. transmissions because a detailed study of these effects seemed likely to be of great value in determining the structure of the ionosphere. Some observations were also made at 80 Mc./s. using the second harmonic of the satellite transmission, to reduce ionospheric effects still further.

With this apparatus we have recorded nightly since October 6 the six to seven transits of the satellite which are observable from the latitude of Cambridge; for each of these transits the track was found, and an approximate orbit of the satellite has been computed. Some new methods of ionospheric investigation have been developed and preliminary results obtained.

The Observational Methods

(*a*) *The Interferometer.* Two aerials were set up on an accurately surveyed east–west line with a spacing of 4λ, and were used with a phase-switching receiver. The choice of spacing was a compromise between the requirements of angular accuracy and the difficulty of establishing the correct lobe identification. The aerials were simple full-wave dipoles mounted at a height of λ/2, so that all tracks passing within the visible horizon would be observed.

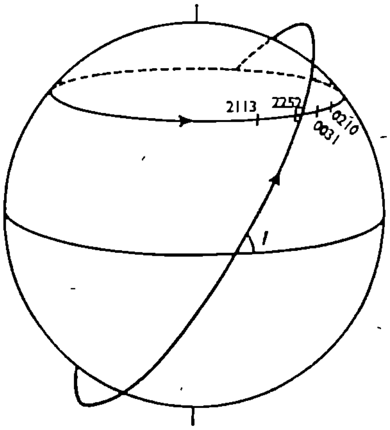

Fig. 2. Diagram showing the orbit in relation to the latitude of Cambridge. The times indicate the approximate position of Cambridge during the successive transits

The interference pattern produced by this system intersects any horizontal plane in a system of hyperbolæ, the form of which will depend upon the height of the plane. The passage of the satellite across these grid lines is obtained from the records as in Fig. 1, from the times at which the trace crosses the central zero.

During the middle of the night, the satellite passes far to the north of Cambridge (Fig. 2).

The linear distance of these tracks may be found by observing the rate of transit across successive grid lines and assuming initially the velocity appropriate to a circular orbit.

This observation provided a measure of the most northerly latitude of the track and thus allowed a preliminary value of the inclination (i) of the orbit to be derived.

From this inclination the angle at which the track crossed the latitude of Cambridge could be calculated and it was then possible to use the observed times of crossing the grid lines, in the manner shown in Fig. 3, to select a unique track and height.

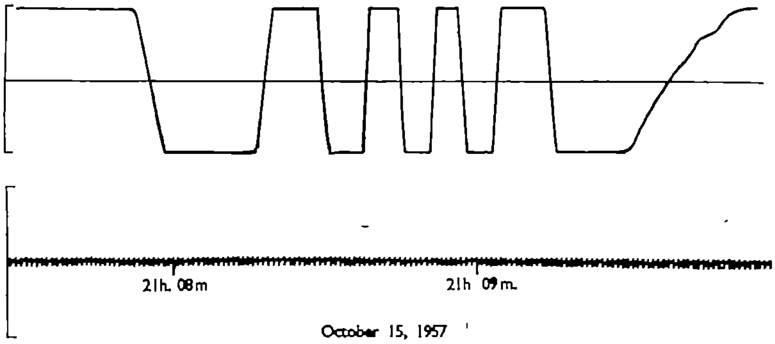

Fig 1. Record of transit of the satellite observed on the interferometer

For the more distant tracks it is necessary to take account of the Earth's curvature, and when a preliminary elliptical orbit had been derived, the variation of the velocity was also included.

(*b*) *The Doppler Method.* In the second method the apparent frequency of the 40 Mc./s. transmission was recorded during each transit, by mixing the received signal with that from a local 40 Mc./s. oscillator, and measur-

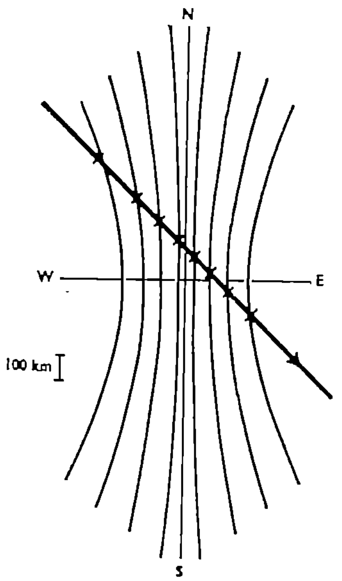

Fig. 3. Grid lines for a height of 630 km. showing the derivation of the track relative to Cambridge

ing the beat note of approximately 6 kc./s.; the latter measurement was done by comparison with a variable audio-frequency oscillator using ear and cathode-ray tube presentation. The readings of the frequency were recorded at intervals of about 3 sec.

The maximum rate of change of the received signal occurs at the time of closest approach of the satellite and is given by fv^2/cr, where f is the transmitted frequency, v the satellite velocity and r the distance of the observer from the track. In practice small corrections must be applied to allow for the curvature of the track and the effect of the ionosphere. The 'slant range' to the track could usually be measured with an accuracy of about 5 per cent, and the time at which the satellite was closest to about 5 sec.

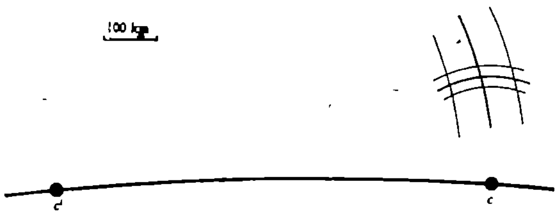

Fig. 5. Derivation of track from slant ranges measured for two successive transits. C' represents the projected position of Cambridge for the previous transit

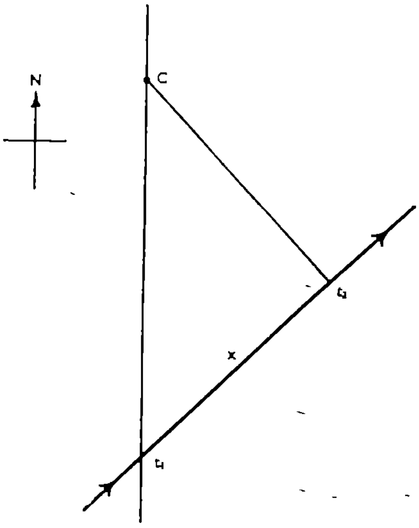

Fig. 6. Determination of the track by combining the two methods

Examples of records obtained for tracks passing within 650 km. and 250 km. are shown in Fig. 4.

By making measurements of the slant range to the track on two or more successive transits, it is possible to determine the true track and height by triangulation. Fig. 5 shows the graphical method used in

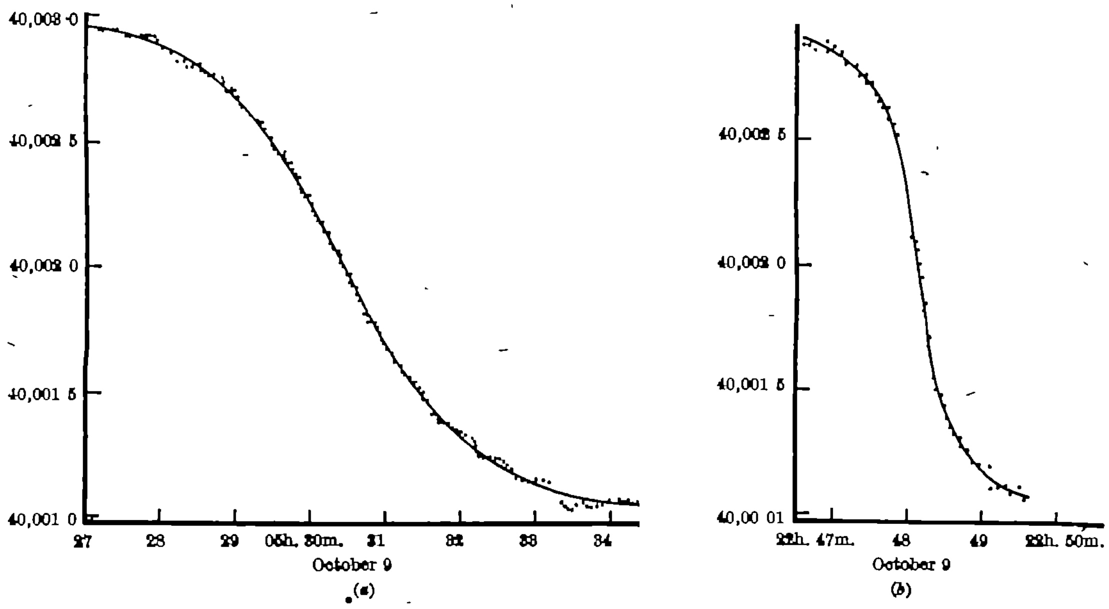

Fig. 4. Variation of the received frequency for tracks having slant ranges of (a) 650 and (b) 250 km.

which the measured slant ranges are projected on to a plane perpendicular to the direction of the orbit at the latitude of Cambridge; the lateral movement of Cambridge between successive orbits allows a normal range triangulation method of plotting to give the height and track of one of the chosen transits.

A similar method based on the measurement on the same transit of the slant ranges from two or more spaced receiving stations was also used; for this method the observations made by the Post Office receiving stations at Baldock and Banbury were combined with our own.

In most of our observations, the results of both interferometric and Doppler methods were combined; the time of meridian transit (t_1) (Fig. 6) and the time of closest approach (t_2) allow a determination of the intervening track x, and hence of the latitude at which the meridian is crossed.

Derivation of an Approximate Orbit

The ground range at closest approach may then be combined with the measured slant range to give the height independently of that derived by fitting the recorded times of crossing the grid lines.

Measurements made during the period October 6–20 have been reduced to provide the following details of the orbit; these figures differ slightly from those published earlier¹ because more detailed corrections have been applied and additional observations have become available.

Full details of the observations have been communicated to the Superintendent of the Nautical Almanac Office, who has undertaken the calculation of the orbit, but in the meantime we have derived a provisional orbit for October 15·0 the details of which are given below:

Inclination	64° 40′ ± 10′
Period between successive northward crossings of lat. 52° 12′	5750·0 solar sec. ± 0·3 sec.
Rate of decrease of period	2·2 ± 0·1 sec. per day
Height at latitude 52° 12′ on northward passage	223 km. ± 10 km.
Height at latitude 52° 12′ on southward passage	470 km. ± 15 km.
Semimajor axis	6,937 km.
Eccentricity	0·053 ± 0·001
Latitude of perigee	36° N. ± 3°
Longitude of ascending node	306° 09′ ± 15′
Retrograde motion of ascending node	3° 33′ ± 5′ per day
Meridian passage at Cambridge on October 15	21 06 41 U.T.
Height above mean radius of Earth at perigee	197 ± 10 km.
Height above mean radius of Earth at apogee	934 ± 10 km.

Because of its interest in connexion with the fall-in of the satellite, the measurements of the true period are plotted in Fig. 7; the present change of period corresponds to a decrease in height at apogee of about 3·5 km. per day.

By extrapolation from the observations, it has been possible to provide predictions of transits over the British Isles for one or two days in advance, with an accuracy of about 50 km. in track, 10 km. in height, and 3 sec. in time of meridian transit.

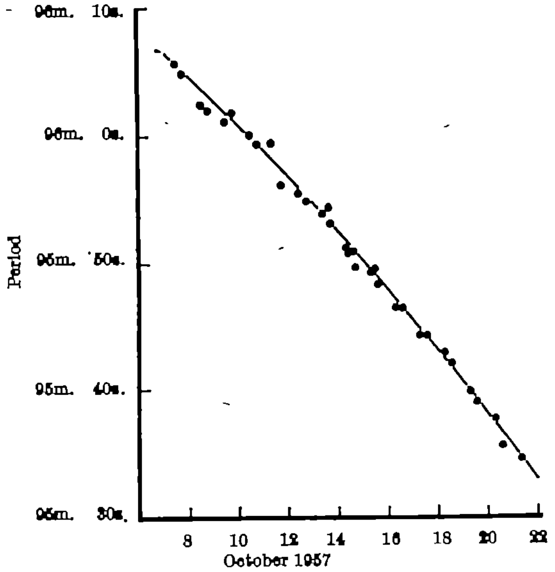

Fig. 7. Variation of the true period

Variation of the Intensity of the Received Signal

The strength of the signal frequency shows remarkable and complicated fading patterns in which regular variations having periods between 0·5 and 10 sec. may be seen. Typical examples are shown in Fig. 8.

A number of effects could contribute to such variations:

(a) Spinning of the satellite could cause a variation of the intensity due to the polar diagram of the transmitting aerial. Such variations might have a frequency f or $2f$, where f is the frequency of spin; the magnitude of the effect will depend on the aerial system and the inclination of the spin axis relative to the aerial axis and the line of sight.

(b) Any plane-polarized component of the emitted signal would produce a variation in the signal received by a linearly polarized aerial if the satellite were spinning; this variation might also have a frequency f or $2f$, depending on the aspect, and its magnitude would also vary markedly with aspect.

(c) The Earth's magnetic field will cause Faraday rotation in the ionosphere, and as the satellite moves

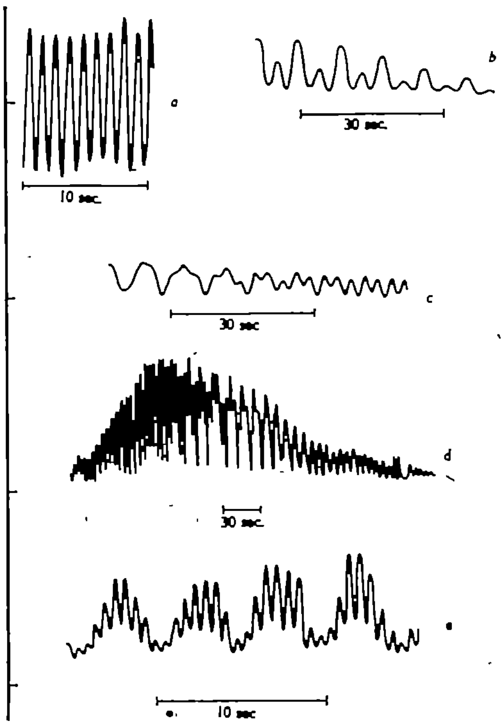

Fig. 8. Examples of fading records

the rotation angle will vary; a plane-polarized emitted wave will therefore be received as a varying signal on a linearly polarized aerial.

In order to distinguish between these possible effects, observations were made on a number of occasions with aerials having mutually perpendicular planes of polarization; we found that the fading patterns of the signals received on the two aerials differed in phase by $\pi/2$, indicating that rotation of the plane of polarization was the predominant cause of the variations.

In order to distinguish between rotation due to spinning and that due to the Faraday effect, observations were made on different frequencies; the Faraday rotation is proportional to λ^2, and will therefore produce faster fading on the lower frequency transmission, while the effect of spinning would be independent of frequency. We therefore made observations on the 20 Mc./s. and 40 Mc./s. transmissions, and also on the second harmonic of the 40 Mc./s. transmissions where the Faraday rotation is only 1/16 of that at 20 Mc./s.

These observations indicated that the satellite is spinning at seven revolutions per minute; the axis of spin could in principle be deduced from records such as Fig. 8 (*b*), which may show the transition of the line of sight through the cone angle traced out by the aerial axis. In practice it is not possible to find the true axis of spin, because it seems probable that owing to the aerial systems the atmospheric drag deduced under the heading "Other Investigations" will not act precisely through the centre of gravity of the satellite. If the effective centre of the frontal area is displaced by more than about 1 mm. from the centre of gravity, the couple exerted by the air drag will cause a precession of the axis of spin of at least ¼ radian per orbit. It is therefore impossible to relate the observed fading curves on successive transits.

Having determined the spin frequency, it is possible to find the true rate of change of the Faraday rotation, and this may be used in the manner described below to investigate the structure of the ionosphere.

Investigation of the Ionosphere

The presence of a transmitter at varying zenith angles and at various heights over Britain between 200 and 500 km. offers the possibility of entirely new methods of ionospheric investigation.

We have considered a number of possible methods, and for most of them we have made preliminary observations. A full study of the potentialities of the different methods has not yet been made, and only preliminary results have so far been abstracted from our records.

The methods we have considered may be summarized briefly:

(*a*) Measurement of the angle of arrival of the 20 Mc./s. and 40 Mc./s. signals by comparing the apparent times of crossing the grid-lines of similar interferometers working on the two frequencies. This measurement allows the deduction of the angle of refraction at different zenith angles.

(*b*) Measurement of the rate of rotation of the plane of polarization due to the Faraday effect; knowing the track and the inclination of the Earth's field to the line of sight, it is then possible to deduce the rate of change of $\int N dh$ up to the satellite.

(*c*) Measurement of the shape of the Doppler curve gives the rate of change of phase path; from a knowledge of the true track, or better from a comparison of the rates of change at two frequencies, $\int N dh$ can again be derived.

Methods (*b*) and (*c*) are considerably simplified if the rays can be supposed to be undeviated; it is therefore desirable to use high frequencies, especially when observing at large zenith angles. In method (*b*) we have therefore made observations on the 40 Mc./s. transmission and on its harmonic at 80 Mc./s.

By making such observations at large zenith angles where effects associated with the Earth's curvature become pronounced, it may also prove possible to determine the distribution of electron density with height, $N(h)$.

Owing to the ellipticity of the orbit, the height of the satellite changes appreciably during the period of observation; it is therefore possible to derive $N(h)$ over a limited range of h directly from the observations of $\int N dh$ throughout the transit. In the present observations this method has not been used extensively, because that part of the track over which the height is changing rapidly occurs at present near sunrise and the satellite is therefore moving in a region which cannot be supposed to be uniform horizontally.

A further possible method of deriving $\int N dh$ has been suggested by the observation that fading which we associate with the spin of the satellite is frequently accompanied by a marked irregularity in the Doppler curves. This effect may be caused by the periodic reversal of the sense of the circularly polarized component of the satellite transmission as it spins; observation of the apparent change of frequency then allows a direct measure of the difference in phase path of the ordinary and extraordinary waves.

We have as yet made no study of the additional variations of signal strength which occur when the satellite is near or below the optical horizon.

Preliminary Results. Some preliminary results have been obtained from the interpretation of the fading curves in terms of Faraday rotation; in this analysis simple curves of the type shown in Fig. 8 (*a*) were selected, and it was found that many of these showed fading speeds at 20 Mc./s. and 40 Mc./s., which were closely proportional to λ^2, as

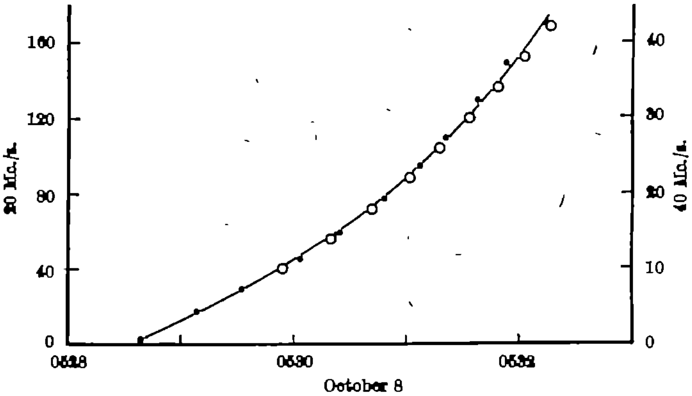

Fig. 9. Variation during the transit of the speed of fading at 20 Mc./s. (●, left-hand scale) and 40 Mc./s. (○, right-hand scale), showing that the speeds are closely proportional to the square of the wave-length

would be expected if the fading were due to Faraday rotation. An example of fading curves in which the spin of the satellite produced a negligible effect is shown in Fig. 9.

From computations of the geometry of transits for which such curves have been obtained it has been possible to determine $\int N dh$ up to the height of the satellite.

For example, observations at 0330 on October 20 when the satellite was at a mean height of 475 km. indicated a total electron content up to this height of $1 \cdot 8 \times 10^{13}$ cm.$^{-2}$.

Other Investigations

(*a*) *Density of the Atmosphere.* The observed decrease in the period of the orbit allows an estimate to be made of the air drag. We have used the published mass of 84 kgm. and diameter of 58 cm. and have neglected the cross-section of the aerials; on the assumption that the gas particles adhere temporarily to the surface of the satellite and leave with thermal velocities, we have estimated that the mass of air encountered in each orbit is 1·8 gm.

Because the orbit is elliptical, this result can only be used to derive the air density if the scale height is known. Assuming a temperature of 1,000° K., the density at a height of 200 km. was found to be about 4×10^{-13} gm. cm.$^{-3}$.

Continued observations of the changes in the orbit should allow the determination of both density and temperature as functions of height.

(*b*) *Precession of the Orbit.* The observed retrograde motion of the ascending node over the period October 8–18 was found to be 2° 33′ ± 5′ per day. For comparison we have computed the expected precession for the observed orbit and the accepted figure of the Earth using the relationship given by Davis, Whipple and Zirker[2], and find a value of 3° 45′.

It does not seem possible to account for this discrepancy in terms of secondary effects of the air drag, or by electromagnetic forces. It is possible that a more detailed analysis of the expected precession may resolve the difficulty, and it is clear that an improved measurement of the precession by continuing the present observations is of great interest.

The work described here has involved practically the whole staff of the Mullard Radio Astronomy Observatory, as well as several of the members of the Ionosphere Section of the Cavendish Laboratory.

Besides our own observations we have been able to make use of a large number of valuable recordings provided by the Post Office receiving stations at Banbury, Baldock and Brentwood, by the Marconi Research Laboratories at Great Baddow and by Mr. F. W. Hyde of the Radio Section of the British Astronomical Association. We are most grateful for their co-operation, and would like to thank all those whose advice we have sought, in particular the Superintendent and the staff of the Nautical Almanac Office.

UNDERWATER SWIMMING AND DIVING

A SESSION of Section I (Physiology) of the British Association, held on September 11, was devoted to the problems of underwater swimming and diving. The meeting was opened by Dr. H. J. Taylor (Royal Naval Physiological Laboratory, Alverstoke), who discussed the physiological aspects, and he was followed by Capt. W. O. Shelford, R.N. (retd.) (Siebe Gorman and Co. Ltd.), who gave an account of apparatus development. M. Frederic Dumas of the Groupe d'Etudes et de Recherches Sous-marines, Toulon, then presented three films illustrating some of the activities of underwater swimmers.

Dr. Taylor opened with a warning against the indiscriminate use of underwater apparatus by the uninitiated. He urged those interested to join recognized clubs, to become well acquainted with the apparatus, to acquire as much information as possible about the hazards of underwater swimming and never to dive alone but always with a companion. In particular he emphasized the serious dangers in the use of oxygen sets by amateurs.

Dr. Taylor said that the problems raised by diving and underwater swimming, quite apart from the technical and engineering aspects, are those of the effect upon the body of exposure to increased pressure.

It is a remarkable fact that in the recent British world record deep dive a man tolerated an exposure to a pressure of 17 tons per square foot. This is because the body, except for some sealed air spaces, is made up of solids and fluids which are, for all intents and purposes, incompressible. Pressure is transmitted to all parts and equalized. This of course implies that air must be breathed at the pressure to which the diver is subjected. A swimmer who makes a dive to 100 ft. (that is, to a pressure of 4 atm. absolute) merely by holding his breath will have his lung volume compressed to about one quarter of its original volume. This is approximately the volume of the residual air, that is, the air left in the lungs after the greatest possible expiration. Any further increase of pressure will produce a condition known as a 'squeeze', and fluid and blood may be forced into the lungs; this damage may be severe. Further increase of pressure may cause the chest wall to collapse. This 'squeeze' may also occur if the pressure of air within the helmet of a diver falls below the external pressure. The shoulders and body will be pushed with great force into the rigid helmet with, usually, fatal results. The ear is very susceptible to damage by pressure, which, when applied to the ear-drums, must be equalized otherwise rupture will occur. This equalization is accomplished by allowing air to pass up the Eustachian tube to the middle ear. This is a procedure which the diver himself must carry out and is known as 'clearing the ears'. Difficulties are sometimes encountered in equalizing the pressure in the accessory sinuses and severe pain may result.

Problems can also arise when the pressure on a diver or swimmer is reduced, particularly when he comes to the surface. Normally, on rising towards the surface the pressure of the air in the lungs is maintained almost equal to the external water-pressure by means of a relief valve on the helmet or breathing apparatus. If the relief valve fails to function or if the ascending man holds his breath a positive pressure may be built up inside the lungs. The lungs would become over-expanded and some air sacs and blood vessels become torn. Air could be forced into the ruptured tissues or blood vessels producing spontaneous pneumothorax in one case or air embolism in the other. The results of this may be serious in the extreme, and recompression to the original depth or deeper is essential in order to prevent fatal consequences. Death has occurred after an ascent from only fifteen feet. These dangers can be overcome only by experience and careful training, and this fact cannot be over emphasized.

There are, however, more hazards due to physiological processes concerned with the respiration of gases under pressure. Almost all gases, even the so-called inert ones—nitrogen and the rare gases—exert their own special effects, when breathed at higher partial pressure than normal.

Oxygen is probably more important from the military aspect than it is from the purely recreational. If it is essential that an underwater swimmer must not give his position away with bubbles, then pure oxygen must be breathed in association with an absorbent for carbon dioxide. The hazards of breathing this gas are, therefore, almost entirely confined to operational duties.

Oxygen produces two effects—the Lorrain–Smith or chronic effect and the Paul Bert or acute effect. The former, in the main, is produced by the irritant effect of oxygen, when breathed at between 0·6 and 2 atmospheres, on the delicate membranes of the lung. Much research on this problem has been carried out, but since the effect only occurs after breathing oxygen for many hours it is not looked upon as being a hazard of diving or other underwater operation.

The Paul Bert or acute effect is much more important. This appears when oxygen is breathed at a partial pressure in excess of 2 atmospheres. The greater the pressure the shorter the time of onset of signs and symptoms of the toxicity of oxygen. In man and other mammals this is characterized by a convulsion, epileptiform in character, and the onset of such an effect in an underwater swimmer can be most dangerous. The depth and duration of underwater operations involving oxygen breathing is therefore severely limited.

Much research has been carried out on the cause of this phenomenon, without, it must be admitted, a great deal of success. This is not surprising since comparatively little is known about epilepsy itself. One of the main theories postulates interference in oxygen breathing with the dual function of hæmoglobin. If oxygen at partial pressures greater than two atmospheres is breathed, then there is sufficient oxygen dissolved in simple solution in the plasma to satisfy the needs of the body under conditions of comparative rest. No reduced hæmoglobin is available, therefore, for transport of carbon dioxide and one might expect an accumulation of this gas in the body tissues. It is suggested, therefore, that the effect is really due to excess carbon dioxide in the tissues. Experimental evidence is available which appears to confirm this idea, since the tension of carbon dioxide in the tissues during oxygen breathing shows a marked rise. In addition, it is known that the respiration of a low proportion of carbon dioxide with the oxygen greatly enhances the effect. However, more recent experiments by some workers in the United States show that there is reduced hæmoglobin available in the brain and the normal removal of carbon dioxide can take place. If it is assumed, as is generally the case, that the brain is the source of the manifestation of oxygen poisoning, then a blow has been dealt at the Gesell hypothesis. The American work is, however, open to some criticism. Other theories are (*a*) that oxygen interferes with brain metabolism, for example, that it affects enzyme systems; (*b*) that neuro-muscular transmission is impaired.

The Royal Navy has been seeking a suitable drug which can be given to an underwater swimmer to increase his resistance to oxygen poisoning, and some success has been obtained.

There is another effect characterized by sudden lack of consciousness at comparatively shallow depths which has been ascribed to breathing oxygen. This is sometimes called 'shallow-water black-out' or 'oxygen syncope'. The cause is obscure, but experimental work is proceeding. It may be due to a cerebral vaso-constriction by oxygen.

Nitrogen, when breathed under pressure, exerts a narcotic action. There is a slowing up of mental processes, and fixation of ideas is a characteristic response. Frequent errors are made in simple arithmetic and in the recording of information. These responses may be similar to those associated with anoxia or with alcoholic stimulation. If nitrogen in the oxygen–nitrogen mixture is replaced by helium, then the effect is much reduced. It may be that the fact that the oil/water solubility ratio for helium is much less than that for nitrogen has some bearing on the problem (cf. the Meyer–Overton law). It has also been suggested that decreased elimination of carbon dioxide due to decreased pulmonary ventilation produced by the heavy gases might be a factor, but measurements of alveolar carbon dioxide under conditions of high pressure have shown this to be normal and have disproved this hypothesis.

Recent work, involving electro-encephalograph records, has been rewarding. Normally the occipital alpha-rhythm shows an abrupt fall in amplitude (blocking) when a subject concentrates on a problem. After exposure to a pressure of four atmospheres in air the time to give an answer to a simple calculation is increased and further exposure leads to abolition of the blocking. On returning to atmospheric pressure, this process is reversed. Using different pressures it is found that the time to abolition of the blocking is inversely proportional to the square of the pressure, suggesting a diffusion process. On replacing nitrogen by helium, blocking is not abolished. It seems, therefore, that nitrogen is responsible for these effects. Consequently, for deep dives a helium–oxygen mixture replaces air.

Nitrogen and all the inert gases produce an effect, only observed when the pressure drops, due to the quantity of gas dissolved in the body. Exposure to these gases under pressure produces an increased tension in tissue, dependent on the depth and duration of the dive and on circulatory efficiency. When a certain quantity of inert gas in the tissues is exceeded, direct decompression to atmospheric pressure will lead to the formation of bubbles and the so-called 'bends'. This has led to the introduction of diving tables; so that a man is not brought directly to the surface but has a series of stops at different depths and times depending on the nature of the original dive.

Several of these diving tables have been produced, but all have some unsatisfactory features. This is because of a lack of fundamental information regarding inert gas exchange in tissue. Research is therefore proceeding at the Royal Naval Physiological Laboratory on this subject and some success has been achieved. It would appear that only one type of tissue is involved, and that saturation and desaturation are not reversible, as has previously been assumed. The removal of dissolved gas on decompression is retarded by the presence of bubbles which may not be of sufficient size to produce signs of bends. The fact that exposure to pressure appears to produce these silent bubbles must be taken into account in the calculation of safe decompression tables.

As regards carbon dioxide, if the absorbent canister is working efficiently in a closed-breathing set there should be no danger from this gas. Nor should it be a hazard in deep diving if the flow of gas is sufficient to wash out the carbon dioxide.

Naturally, there was not sufficient time to enlarge on all the problems arising from diving and underwater swimming. Such a one as protection from the cold was not mentioned, but it has its importance. There is, however, one phenomenon which is becoming more and more important as dives become deeper and deeper, and that is the voice-change produced by increased pressure and also by breathing helium. Communication thus becomes more and more difficult, and the audience was asked to listen to a tape recording of a man speaking under pressure. The explanation of this effect is not yet clear, but in the recent world deep dive to 600 ft. it was found almost impossible to understand what the diver said.

This recording was of an Irishman repeating the well-known verse, "In Dublin's fair city . . . singing, cockles and mussels alive, alive O !" at a pressure of 132 lb./sq. in. (about 264 ft. of sea water). The euphoria and speech distortion produced by nitrogen under pressure were well illustrated.

Capt. W. O. Shelford spoke next; he classified diving apparatus into four types: (1) self-contained closed circuit; (2) self-contained open circuit; (3) surface-supplied open circuit; (4) surface-supplied closed circuit.

The best known set of the first group is that designed by Sir Robert Davis for submarine escape. This involves the use of pure oxygen, carbon dioxide being absorbed by 'Protosorb'. Other forms of oxygen diving apparatus were greatly used during the Second World War for all types of offensive operations. The great advantage of oxygen is the compact nature of the set and the absence of tell-tale exhaust bubbles. It also gives great endurance, for example, that used by human torpedo-men had a tested endurance of six hours in 25 ft. of water with a considerable margin of reserve. One of the greatest problems in this sort of set is the absorption of carbon dioxide. Much valuable research work was carried out at the Chemical Defence Experimental Establishment, Porton, both on canister design and in the control of the absorbent chemicals.

A great advance was made during the Second World War in the use of mixtures of oxygen and nitrogen for breathing in a semi-closed circuit apparatus. The theory of mixture breathing was developed by Prof. J. B. S. Haldane and Dr. K. W. Donald and the idea is to give as much oxygen as possible in the mixture (and so provide maximum endurance) consistent with the least danger of oxygen poisoning. The optimum concentration of oxygen depends upon the depth of the dive. The set is a semi-closed circuit one giving partial rebreathing with a flow fixed according to the depth by a regulator which is compensated automatically for change in sea pressure. The regulator delivers a constant mass of gas at any diving depth. Mixtures have been used in Britain for many years with success, and Norway and the United States are now beginning to experiment with their use. The French have recently developed a mixture breathing set which supplies gas on demand without the use of a regulator.

Possibly the greatest interest since the War is in the compressed-air open-circuit apparatus. This is commonly known as the aqualung and its use has been popularized by Capt. Cousteau, M. Frederic Dumas and their associates. Air is stored in bottles at high pressure and delivered to the diver at the pressure of the surrounding water to be compensated instantly as the diver descends or ascends. This has to be done by a demand valve capable of supplying sufficient air to a diver even when he is making the maximum possible inspiratory effort. Being an open-circuit apparatus, the endurance varies with the depth. As regards surface-supplied open-circuit apparatus, there is the standard rigid-helmet type which has been in use for more than a hundred years. No change in principle—which is to compress air on the surface and supply it to the diver by a hose at a pressure equivalent to his depth—has been made, but naturally, suits, compressors and all ancillary equipment have improved. A recent variation is to supply air to the diver at about 100–50 lb./sq. in. and he regulates his own supply by breathing from a demand valve.

This last class of diving is that using the partial self-contained closed-circuit system, almost exclusively in very deep diving. On open circuit it was found that carbon dioxide tended to accumulate in the helmet due to pocketing. This led to the adoption of the Siebe-Gorman injector re-circulating system which was applied to the standard diving dress. In this system, air is supplied at a pressure higher than the ambient sea pressure, sufficient to maintain a constant flow through an injector. This injector feeds into a Venturi tube, creating a partial vacuum in a carbon dioxide absorption canister worn on the back of the diver. The air containing carbon dioxide is therefore drawn through the canister and back into the helmet. Very much less air from the surface is therefore required. As diving depths become greater so the problem of nitrogen narcosis becomes more important. Nitrogen is therefore replaced by helium. At first considerable difficulties were encountered and the construction of the helmet had to be improved still further and, since helium is so much less dense than nitrogen, new injectors and venturis had to be designed.

World record dives to 540 ft. in 1948 from H.M.S. *Reclaim* under Capt. Shelford's command and to 600 ft. from the same ship in 1956 testify to the success of these developments.

Another field in which considerable advance has been made is that of divers' clothing. Two-way stretch nylon, proofed with neoprene, is being used to give a supple suit with maximum protection properties. Despite much research, it is still thought that the standard diving woollen undergarments are the best for protection against cold.

Capt. Shelford went on to predict further developments. He foresaw a time when all suits would be of rubber- or neoprene-proofed 'Terylene' fabrics fitted with light-weight ball-race shoulder and waist joints. The special copper helmet inside which the diver rotates his head may be replaced by a comparatively tight-fitting helmet rotating and elevating at the neck joints so that its volume and buoyancy can be greatly reduced. There could be considerable development in the open-circuit aqualung set if new materials, allowing for greater charging pressures, were allowed by the authorities for the construction of cylinders. Capt. Shelford ended by saying that he had no doubt that industry would supply any equipment which the scientist needed to provide for deeper and deeper depths.

The last part of the meeting was devoted to the showing by M. Frederic Dumas of three films. The first, in black and white, was of some of the experiences of cave diving. The film started by giving an insight into the organization required before such a project could be undertaken, how the interest of the local population was aroused and how the morale of the divers was maintained in the local cafés. In the caves themselves the pictures were most fascinating, particularly when attempts were made to find the sources and direction of flow of the water.

The second film, in colour, was an account of an exploration for oil in the Persian Gulf carried out for the Kuwait Oil Company. Fine seascapes and pictures of fish and animal life were shown. A cage for protection against sharks was a reminder of one of the special hazards in this sort of work.

The third film, again in colour, showed the discovery and investigations of some Roman galleons sunk in the Mediterranean. Marble pillars and other portions of buildings which were being transported in the galleon when it sank were in a remarkable state of preservation. Later, the film showed how an underwater swimmer can help in tunny fishing. This looked particularly hazardous, but M. Dumas assured his audience that this was not so.

During the subsequent short discussion members of the audience gave accounts of the work of their own sub-aqua clubs, endorsing the warnings that Dr. Taylor gave earlier on. Questions were asked about the reported failure of some men to carry out quite simple tasks at shallow depths, when nitrogen narcosis could be ruled out. It was suggested that this was probably due to apprehension and anxiety.

H. J. TAYLOR

THE ORIGINS OF LIFE

MOSCOW SYMPOSIUM

THE Academy of Sciences of the U.S.S.R. acted as generous host to the first of the specialist symposia that the International Union of Biochemistry has decided to arrange in years when there is no international congress. The symposium was organized by Prof. A. I. Oparin; it was on "The Origin of Life on the Earth", and this is also the title of the new edition of a book by him that Dr. Ann Synge has recently translated into English.

About sixty papers were circulated, read in summary, and then discussed during three and a half well-filled days. This was certainly the most ambitious attack on the problem that has as yet been made, but, contrary to the claim that was often made at the symposium, it was by no means the first serious scientific attack on it. At the end of last century and the beginning of this one the British Association dealt with the subject regularly. Huxley, Tyndall, Schafer and others had a clearer grip on the nature of the problem than most contemporary writers. They also often have priority. If participants in future symposia on biopoesis would read the old literature we might be spared the embarrassment of hearing eminent scientists portentously making suggestions that were familiar 50–80 years ago.

There is now general agreement that life can arise from non-living matter but there is disagreement about how often it does so. The possible points of view are set out in Table 1. Possibilities 1 and 2 are not now often advocated, but 1 will soon become amenable to experimental test when astronauts set out to look for what Haldane calls "astroplankton". Possibility 5 was effectively disproved during last century, not so much by the work of Pasteur as by the existence of the food-canning industry. That leaves 3 and 4. Many people advocate 3 because they claim that the biochemical uniformity of present-day life, and the preponderant use in proteins of amino-acids of only one of the two antipodal series, suggests a common origin. This point of view was maintained at the symposium by R. L. M. Synge; but it does not seem to me to pay sufficient attention to the operation of food chains in Nature. If any group of organisms started to use one antipodal series it would be advantageous for any other group, even slightly dependent on the first, to come into line. And there are obvious advantages in using one series only. Though biopoesis is probably a rare event it is probably not a unique

Table 1. BIOPOETIC THEORIES

	No. of biopoeses	General character
1	None	Life has always pervaded space and an apparent origin is simply a transfer from place to place
2	One	Creation by divine intervention
3	One	Evolution on Earth by the action of inevitable, normal processes
4	Several	Repeated co-ordination of eobionts or sub-vital units
5	Innumerable	Classical and medieval idea that life appeared whenever there was a suitable environment

one. Disproof of this point of view will be difficult. It is hard to experiment on rare events and, as Darwin long ago pointed out, any new intruder into the living domain would now be immediately used as food by a longer established organism.

The Moscow discussion, like most similar discussions, got bogged down from time to time in metaphysics about the nature of life. In spite of official adherence to a Marxist materialist philosophy, a surprisingly large proportion of the Russian participants appeared to be Platonic Idealists. They realized that they could neither define nor unequivocally recognize 'life', but they were none the less certain that there was such an entity to be recognized. This was also the attitude of many members of the group from the United States. Even the 'cold war' cannot contend with Idealism. My attitude, which might be labelled Empirical Nihilism, is that the statement that a system is or is not alive is a statement about the speaker's attitude of mind rather than about the system, and that no question is scientifically relevant unless the questioner has an experiment in mind by which the answer could be approached. When we are concerned with extreme states, such as the higher plants and animals on one hand and rocks and chemicals on the other, there is little uncertainty. It is when the borderline is being considered, as with viruses or some metabolically active fragments from cells, that definition could be useful and is impossible.

The size of the atomic symbol is an indication of the contribution that element may have made to the process at the time.

Fig. 1

But the history of science offers many examples of useful discussions on ill-defined or undefinable themes. The Moscow symposium was another. The first few papers were on the chemical nature of Earth's probiotic atmosphere and surface; they demonstrated that there is no basis for dogmatism. Of particular interest was the revival by P. N. Kropotkin of the idea that petroleum could have a non-biological origin. The case that was made out was so convincing, although the idea has been condemned by most authorities for half a century, as to suggest that many other possibilities that are now neglected might be re-investigated. There were then several papers on the types of synthesis that proceed when mixtures of the various substances that have been postulated in the primitive environment are exposed, in the laboratory, to energy sources as diverse as heat, electromagnetic radiation and radioactivity. These demonstrate, what most biochemists have been prepared to assume, that there is no difficulty in postulating a chemically complex 'probiotic soup'. If a theory of biopoesis demands the presence initially of any particular type of chemical compound it would be foolhardy to deny the possibility of its synthesis. It is good to have our assumptions justified; but the main value of this type of experimentation now seems to lie in the possibility that these syntheses may have industrial applications.

The greater part of the symposium was taken up with papers the relevance of which depended on the assumption that life can only exist as a result of the activities of proteins, nucleic acids, high-energy phosphates or whatever type of compound is at the moment fashionable. Undoubtedly all the present-day organisms that have been studied contain all these substances; they also contain fats, carbohydrates and so on. In these circumstances it seems invidious to pick any one as the *sine qua non* of life. We are not even justified in assuming that there was any single type of substance in this unique position. It is just as likely that primitive forms of life, or eobionts, made use of many different mechanisms, and that the mechanisms we see now are the end result of an immense process of evolution and selection. Proteins may be the most efficient rather than the only vehicle for living. On this view a detailed discussion of the contemporary metabolic behaviour of amino-acids, nucleic acids or proteins may have no more to do with the origins of life than a study of the mechanism of a cigarette lighter has with the origins of fire making. Extending this type of scepticism, there is also no reason for the general assumption that life has, at all epochs, been predominantly the affair of the carbon compounds. Small, atypical regions, in which elements that no longer play a large part quantitatively were concentrated, may have been the sites of biopoesis.

This outlook is illustrated crudely in Fig. 1. There are two cones set apex to apex and the diameter of a cone (the abscissa) at any level of time (the ordinate) represents the number of different ways in which systems with living or lifelike properties worked. The lower cone represents an immense chemical diversity narrowing down as a result of biochemical selection to give a few forms of life operating on a more restricted group of efficient chemical mechanisms. From that point on there has been little or no increase in biochemical complexity but there has been the immense increase in morphological complexity with which we are familiar and of which fossils give evidence. The great difficulty of discussions on the origins of life is that they are attempts to describe events long before the beginning of the fossil record; metaphorically, they are attempts to see through the apices of the double cones.

Two courses are open. One is an intensification of geochemical studies, and if they are to be useful it is important that they should not be conceived narrowly but keep all the biopoetic possibilities in mind. The other is to follow the course of evolution backwards to see if the apparent direction, in the period about which we have evidence, can be used to give hints about the period before that. M. Florkin attempted this for aspects of the metabolism of complex molecules, and I did so for some of the elements. Florkin showed how often a substance that seems perfectly adapted for one role appears in more primitive organisms filling an entirely different one. Thus oxytocin exerts uterine control in mammals but controls water metabolism in amphibians. Furthermore, as evolution proceeds there is good evidence for biochemical simplification. Haldane, who unfortunately was not at the symposium, has already argued that the only exception to this generalization is protein synthesis, which seems to get more elaborate in the higher organisms. If this is indeed so, and if we follow the logic of the generalization, it suggests that proteins, far from being the original essential vehicles of life, are a relatively recent innovation. The efficiency given by proteins may have made them dominant. Thus it is the vertebrates that use them for nearly all purposes, structural as well as catalytic. As we descend the evolutionary scale their structural and protective functions are increasingly taken over by polysaccharides and matrices loaded with mineral crystals. The use of the elements suggests a similar trend. It is primitive organisms and not the most highly developed that have the most catholic approach to biochemistry and use vanadium, selenium, the halogens, aluminium, silicon and so on, most readily. That is why I give all these elements an equal status with the contemporary bio-elements on the base of the lower cone of Fig. 1.

If this approach to the problems of biopoesis is valid it follows that the most relevant contributions that comparative biochemistry could make would come from a detailed study of the most primitive contemporary organisms and of those organisms which, although able to live in an environment free from other metabolizing systems, nevertheless have extremely limited synthetic capacity. The first group includes such things as sponges, ferns and liverworts; a study of their peculiarities would give us more information about the range of activities of which the now extinct forms of life may have been capable. The second group includes those saprophytic bacteria that need the most elaborate media for growth, for they probably have the smallest range of intrinsic metabolic ability and so would give us information about how small a group of co-ordinated metabolic activities is needed to satisfy at least some of our æsthetic requirements for a living system. It is unfortunate therefore that most attention was devoted at the symposium to viruses and autotrophic bacteria. The former are irrelevant because they do too little and only exist by courtesy of the synthetic mechanisms of a highly evolved host; the latter because they do too much. They are indeed able to carry out almost all the general biochemical operations. All these capacities could scarcely have developed simultaneously in an early form of life. It is more probable that they are a response to the competitive stresses of more recent times.

Argument about evolution presents many intellectual pitfalls for the imprudent. J. D. Bernal fell into some of them with consequent inversion. This was the position in which, according to Engels, Marx found Hegel. Marx put Hegel on his feet and put posterity in his debt by making the Dialectic useful; I would like to perform a like service for my friend. In the course of making some valuable points about the relationships that will necessarily exist between particles as systems get more complex, he erected the principle of "structural conservatism or inertia" and resurrected L. J. Henderson's old illusions about the "Fitness of the Environment". "Inertia" only amounts to the fact that, when selection has operated efficiently enough to give an organism mechanisms or structures well adapted to the circumstances in which it lives, any change is likely to be a change for the worse. This is a consequence of having achieved reasonable success and it obtrudes itself of necessity in the activities of organisms with a long evolutionary history. The concept of "Fitness" led Henderson towards God; Bernal is a Materialist so it only leads him into trouble. The proposition is that the chemical and physical properties of water, carbon dioxide, etc., are uniquely fitted to give organisms a comfortable environment: and the argument seems plausible until we realize that that is why organisms have evolved with the properties we know. The environment selects those that fit it. It is no accident that the environment suits proteins; had it been different another group of substances would have assumed the dominant role that proteins have in this one. Thus in an environment of liquid ammonia and methane, such as is postulated by some on Jupiter, there would be less need to have macromolecular catalysts, like proteins, because Brownian movement would not be jogging the catalyst's elbow all the time. The reactions there on which life, if any, depends will be slow, but the universe does not seem to be short of time. If Jovial scientists are not very thoughtful they have probably concluded that nothing resembling life can exist on Earth except perhaps in the middle of Antarctica where the sort of molecules that evolution may have selected on Jupiter could be stable. The basic illusion is to assume that ours is the only way of living.

The symposium was valuable because it gave an opportunity for discussion and produced some papers with new relevant information and points of view, and some that may not have been strictly relevant but were sound. It also produced some new nonsense and some nonsense that was not even new; the paper by W. M. Stanley, with the modest title "On the Nature of Viruses, Genes and Life", was outstanding in the last category; he decided that multiplication was an infallible index of the living or non-living status of a system.

Now that the initial step has been taken, it is very much to be hoped that further symposia will be held on themes related to the origins of life. They will produce no succinct answers to the more general questions; but they are essential if the problem is to be defined and if people working in all the different relevant sciences are to see the bearing that their work has on it.

N. W. PIRIE

OBITUARIES

Sir John Parsons, C.B.E., F.R.S.

JOHN HERBERT PARSONS, who died on October 7, was born in 1868. He was educated at the University of Bristol, where he won many distinctions, and at University College, London. In 1890 he obtained the B.Sc. (Lond.) with honours in physiology. This subject remained his main interest, especially that part of it which concerned visual and cerebral function.

He qualified from St. Batholomew's Hospital in 1892 with the M.B. (Lond.). In 1900 he obtained the B.S. (Lond.) and the F.R.C.S. Eng. In 1901 he was granted a British Medical Association Scholarship and in 1904 obtained the D.Sc. (Lond.).

Parsons decided to become an ophthalmic surgeon, and his first appointment was as curator and librarian to the Royal London Ophthalmic (Moorfields Eye) Hospital. In this post he had control of the pathological laboratory and there laid the foundation and did the necessary research for his great work, "Pathology of the Eye", published during 1904–8. This became the standard work on this subject, and even to-day is a much-used work of reference.

In due course he became surgeon to the Moorfields Eye Hospital and ophthalmic surgeon to University College Hospital and also for a while to the Hospital for Sick Children, Great Ormond Street, London.

Parsons's private practice was carried on at 54, Queen Anne Street, in the house previously occupied by his senior colleague, Mr. Marcus Gunn. The practice grew rapidly, but in spite of this and his ordinary work at the hospitals, he continued his laboratory and research work. In 1903 he was Arris and Gale lecturer at the Royal College of Surgeons. In 1904 he was awarded the Middlemore Prize in ophthalmology and in 1907 the Nettleship Gold Medal. In 1907 he published a small text-book, "Diseases of the Eye". This became very popular, and its tenth edition appeared in 1942.

In the last years of the First World War he was appointed consulting ophthalmic surgeon to the Army in the United Kingdom, and was given the rank of colonel A.M.S., with the task of co-ordinating and regulating the ophthalmic work of the Army. The result was as perfect an eye service as could be managed with the available resources.

All this special knowledge was of use to various ministries and institutions. In 1919 he served on the Advisory Committee of the Air Ministry and in 1922 at the Admiralty; at the Board of Trade on various subjects—sight tests, factory lighting, prevention of blindness; and on the Royal Society's Committee on Glass Workers Cataract. In 1928–32 he was a member of the Medical Research Council. In 1919 he was appointed C.B.E., and in 1922 he was knighted.

In 1919 he was president of the Illuminating Engineering Society and many will remember his inaugural address on "Glare".

In 1917 the *British Journal of Ophthalmology* was founded by the amalgamation of several small publications, and Parsons became the chairman of the editorial board. He devoted much time to this, and it is due to him that this journal obtained and maintained such a very high standard. He continued this work until his retirement from practice in 1939.

In 1936 he was awarded the Howe Medal (United States), and this was a tribute to his international standing as a scientific ophthalmologist. It was during these years that many honours came to him—Hon. LL.D. Edin., Hon. D.Sc. Bristol, Fellow of University College, London, Fellow and president of the Royal Society of Medicine, president of the Ophthalmological Society of the United Kingdom, honorary member of the American Medical Association and of the Australian Ophthalmological Society. Then came the theoretical books, "Mind and the Nation" in 1918 and "Introduction to the Study of Colour Vision". These earned him election to the Royal Society in 1921, and in that year came the "Introduction to the Theory of Perception", which set the seal on his eminence as a philosopher and scientist.

Parsons was a tall, thin man, very modest, rather shy, and he eschewed publicity. He appreciated economy in the use of words, and this sometimes made his published works difficult to follow. He was a shrewd judge of people, no respecter of persons and possessed a mordant wit. The outstanding feature of his character was his intellectual honesty: no hypocrisy, no humbug, no attempt at placating people, no dubious compromises and no pretence. Altogether a life devoted to science and to the welfare of humanity.

A. HAROLD LEVY

Dr. Kathleen M. Drew

THE death of Dr. Kathleen M. Drew (Mrs. Wright Baker) on September 14 has brought to a tragically early close a career of distinguished and devoted work in phycology in the very difficult field of the red algae. Most of this work was associated with the Department of Cryptogamic Botany in the University of Manchester, where she graduated in 1922, and later worked as a member of staff and as research fellow, first with Prof. W. H. Lang and later with Prof. C. W. Wardlaw; she received the degree of D.Sc. of the University of Manchester in 1939. Dr. Drew was one of the earliest of the Commonwealth Research Fellows and spent two years in the United States, chiefly at the University of California, where some of her early systematic studies on the red algae culminated in the publication of her monograph, "A Revision of the Genera *Chantransia*, *Rhodochorton*, and *Acrochaetium*"; in later studies of this period of her work, for example, on *Spermothamnion* and *Plumaria*, she developed the cytological techniques which formed a basic part of her later work.

After her marriage with Prof. H. Wright Baker, she maintained and developed her interests in the red algae with singular success alongside those of her very happy family life. With the publication in 1944 in *Biological Reviews* of her review on the nuclear and somatic phases in the Florideae, she set the stage for the later developments in her work, where she made notable advances in linking morphological and cytological observations with cultural and physiological investigations into the life-histories and inter-relationships in the Rhodophyceae, that most varied and interesting group of algae. Perhaps one of the most striking results of this experimental attack was the identification of *Conchocelis rosea* as a deep-water, shell-inhabiting phase in the life-history of *Porphyra umbilicalis*, on which she was preparing a further series of investigations.

Dr. Drew's numerous publications have appeared in many scientific journals. She was planning to start work on a book; and though we shall not now have this wider expression of her views, it is indeed fortunate that from time to time she had written articles such as those which have appeared in the *Botanical Review*, *Biological Reviews*, *Phytomorphology*, and in the chapter which she contributed to the "Manual of Phycology", which have reviewed the contemporary position as she interpreted it for the field which she had made so notably her own. She was a familiar figure at international congresses and meetings, which she often attended as an invited speaker.

Dr. Drew was much concerned with the future of phycology in Britain, and felt strongly the need to train younger workers in this field. With this aim in mind, she was one of the prime movers in the formation in 1952 of the British Phycological Society and was its first president. The Society owes much to her enthusiasm and wise guidance during its early years; she was regular in her attendance at its field meetings, and there are many younger botanists who will miss her critical and kindly help on these occasions. For colleagues and research students alike, her place can never be filled. Her work was characterized by outstanding integrity of mind and purpose, and unsparing devotion to the exacting demands of difficult techniques; and these same qualities gave a special value to her advice or help in a variety of fields. To her research students, who came from many parts of the world, Dr. Drew was a stimulating and readily accessible supervisor, as keenly critical of their work as she was of her own; and all of them will have grateful memories of her kindly hospitality and sympathetic friendship.

MARY CALDER

NEWS and VIEWS

The Artificial Earth Satellite: Observations at Jodrell Bank

AFTER the Russian announcement of the artificial Earth satellite, emergency arrangements were made at Jodrell Bank Experimental Station (University of Manchester) to bring the steerable radio telescope into action as a radar instrument for the detection of the rocket and satellite. Success was achieved on October 11 when both the rocket and satellite were located by radar. Afterwards, measurements were made on two frequencies, out to ranges limited by the Earth's curvature. In addition to this radar work with the telescope, the radio emissions from the satellite have been studied with interferometric and pencil beam systems. It is hoped to publish a detailed account of this work in the near future.

The Schmiedeberg Award: Dr. E. P. Pick

DR. ERNEST PETER PICK, of the Merck Institute for Therapeutic Research, New York, has received the Schmiedeberg award of the German Pharmacological Society for significant contributions to the progress of pharmacological science. Dr. Pick, who was born in Jaromer, Bohemia, in 1872, and graduated from the German University of Prague in 1896, starting his career as a biochemist in the laboratory of Franz Hofmeister at the Strassburg Physiologico-Chemical Institute. Here Dr. Pick made major contributions to the chemistry of proteins by isolating and characterizing pseudoglobulin and euglobulin, (now known as gamma globulin).

In 1899 he joined the Austrian State Serum-Institut in Vienna, where under Paltauf he became familiar with bacteriology, serology and immunology. It was here that, jointly with Obermeyer, Dr. Pick investigated the chemical properties of antigens and laid the groundwork for Landsteiner's later researches on blood groups. In 1911 Dr. Pick joined Hans Horst Meyer's still young Experimental Pharmacological Institute, where he remained as an assistant until 1924, when he became professor of pharmacology in the University of Vienna. From 1932–33 he was dean of the Vienna Medical Faculty and chief of the Austrian Federal Pharmacological Drug Research Institute.

In 1939 Dr. Pick joined the Merck Institute for Therapeutic Research, which enabled him to continue his scientific research at its laboratories in Rahway, New Jersey. To-day, at eighty-five years of age, he continues as a consultant to the Institute, travelling twice a week to its laboratories to continue his researches, which at present relate to the effect of vitamin B_{12} on cholinesterase. During this period he has also been clinical professor of pharmacology at the College of Physicians and Surgeons, Columbia University, New York City, and associate pharmacologist at the Mount Sinai Hospital, New York. Dr. Pick has made fundamental contributions to research problems in a variety of fields, including the fractionation of proteins, mechanism of shock ('Lebersperre'), and the site of action of hypnotics in the brain.

Edmund Davy, F.R.S. (1785–1857)

EDMUND DAVY, who died one hundred years ago on November 5, 1857, made many original contributions to chemistry, but his fame has been completely overshadowed by that of his cousin, Sir Humphry Davy. He was born in 1785 at Penzance, where he received his early education. In 1804, through the influence of his cousin, who was the first professor of chemistry and director of the laboratory at the Royal Institution, he was appointed operator and assistant in the chemical laboratory. The director's laboratory book on September 13, 1809, contains this entry: "The laboratory must be cleaned every morning. . . . It is . . . the duty of Mr. E. Davy to see that it is done and to take care of and keep in order the apparatus". In 1813 Edmund became professor of chemistry at the Royal Cork Institution, and in 1825 he was elected to the chair of chemistry at the Royal Dublin Society. His scientific merits were recognized when on retiring after thirty years he was awarded his whole salary. His honours included fellowship of the Royal Society and honorary membership of the Société Française Statistique Universelle. An enthusiastic advocate of the extension of scientific knowledge, he founded popular lectures in most of the provinces of Ireland. He was interested in the application of chemistry to agriculture and wrote "An Essay on the use of Peat or Turf, as a means of promoting the Public Health, and the Agriculture, of the United Kingdom" (1850). Among his original work in organic chemistry may be mentioned early experiments on oxymuriatic acid in 1811 and his discovery in 1836 of a hydrocarbon with the molecular formula C_2H_2. Acetylene was obtained synthetically in 1862 by Marcel Berthelot. In a letter dated January 13, 1817, Sir Humphry Davy wrote that he had received the credit for his cousin's process of improving bread by magnesia. Edmund Davy died at Kimmage Lodge, County Dublin, at the age of seventy-two.

Biophysics Research at King's College, London

THE University of London (King's College) has accepted a grant from the Rockefeller Foundation of 121,000 dollars, to be used over the next three years for research in biophysics under the general direction of Prof. J. T. Randall. The new grant marks the continuation of the Foundation's support for this field of research at King's College initiated in 1947. The grant is a recognition of the increasing importance of the contribution of biophysics to the fundamental understanding of biological processes and to the scientific basis of medicine. During the past ten years the Wheatstone Laboratory at King's College has made outstanding contributions[1] to our knowledge of the nucleic acid of the cell (DNA) under Dr. M. H. F. Wilkins, who is deputy director of the Biophysics Research Unit; and Prof. Randall's own group has led the way to the solution of the structure of the collagen of connective tissues and its fibrogenesis. Dr. Jean Hanson's studies (in collaboration with Dr. Hugh Huxley at University College, London) of muscle structure have developed new conceptions of the mechanism of contraction (see *Nature*, 173, 973; 1954). Dr. D. M. MacKay has recently been engaged on problems of visual perception (see *Nature*, October 26, p. 849) which may well be of clinical value and are expected to add to existing knowledge of the working of the cerebral cortex. The Foundation's new grant will be used to maintain and amplify the effort in all these fields of research, which have a fundamental bearing on several important aspects of medicine.

Royal Society of Arts Endowed Prizes

THE following awards have been made by the Royal Society of Arts as a result of its offer of Endowed Prizes for 1957: Howard Prize of £50 for a treatise on some aspect of the subject of motive agents to Mr. A. E. Johnson, of East Kilbride, Lanarkshire, for his work on "Turbine Disks for Jet Propulsion Units: an account of Work of the Disk Panel of the Ministry of Supply, Gas Turbine Collaboration Committee, during the years 1941–49"; Fothergill Prize of £20 for fire prevention or fire-fighting to Mr. P. B. Smith, of Chapel-en-le-Frith, Cheshire, for his essay "A New Method of Suppressing Fires in Mines". In the opinion of the judge, this entry records the most novel suggestion that has appeared for a number of years.

Expansion of the Imperial College of Science and Technology

THE number of students at the Imperial College of Science and Technology has risen by 235 since last year and now stands at 2,450. Since the College's expansion programme was started in 1953 the number of students has increased by 800. The rector, Dr. R. P. Linstead, speaking at the College's Commemoration Day ceremony held in the Royal Albert Hall on October 24, said that fifteen new professorships and readerships in the University of London have been established and filled at the Imperial College in the past twelve months. Plans for new halls of residence are well advanced; approval has been received for the clearance of existing derelict properties on the south, east and part of the north sides of the Princes Gardens site to make way for the new halls (*Nature*, 179, 613; 1957), among which is to be Weeks Hall, for which a gift of £150,000 by Messrs. Vickers, Ltd., was announced in March.

Festival of Films in the Service of Industry

THE premier award in the "Films for Use in Schools" section of this Festival, recently held in Harrogate, was won by "Mirror in the Sky"—a film intended to stimulate scientific interest among pupils of the middle-school age group. "Mirror in the Sky" was sponsored jointly by Mullard, Ltd., and the Educational Foundation for Visual Aids, and produced by Realist Film Unit, Ltd. It is part of the United Kingdom's contribution to a series of modern science films being produced by countries of Western European Union. The subject is the ionosphere and its significance in radio communication; the work of Sir Edward Appleton in proving the existence of the second, higher atmospheric layer which bears his name is outlined.

Exhibition of New University Architecture

AN exhibition of examples of new university building, admission free, will be held in the Chancellor's Hall, Senate House, University of London, during November 2–15. More than £12 million a year is at present being spent on a programme of reconstruction of universities in the United Kingdom, and it is of great importance that the new buildings should have lasting architectural merit and make a visual contribution to the education of students who live and work in them. The exhibition, which consists of photographs, plans and original drawings of university buildings in Britain and overseas, is roughly divided into sections dealing with lay-out, science buildings and residential areas. At the end of the exhibition the scale is brought down to individual objects that explain in a more tangible way the standard of quality that should obtain throughout universities. The exhibition, which has been arranged by the University Architecture Exhibitions Committee with the support of the Arts Council of Great Britain, will later visit the following university cities: Oxford (November 25–December 10), Cambridge (January), Birmingham (February), and Leeds (March).

"From Coal to Coke"

IN the Sixth Coal Science Lecture, organized by the British Coal Utilization Research Association, and given at the Institution of Civil Engineers on

October 16, M. Cheradame (of the Centre d'Etudes et Recherches des Charbonnages de France) gave an insight into some of the problems affecting the production of coke in France, and described the researches which his organization had undertaken in an effort to solve them. For many years the French have found it difficult to use certain of their indigenous coals to produce a coke suitable for the blast furnace. Hence, a major task facing the research organization of the nationalized French coal industry has been the investigation of means for producing a good metallurgical coke from the highly swelling coals of the Lorraine, where most of France's iron ore occurs. M. Cheradame recalled that early research into coke-making was largely of an empirical kind. Since 1950, however, basic researches carried out at the Verneuil Laboratories had been supplemented by practical tests on full-scale ovens erected for the purpose at Marienau in the Lorraine coal field. In M. Cheradame's view, three main ideas would dominate future research on coking. These were, first, that the chemical use of hard coal in the form of metallurgical coke was advantageous and should be developed; second, that anthracite and, more generally, smokeless fuels should be used for solid fuel domestic heating; and third, that the range of coals which could be coked corresponded, in many countries, to too small a proportion of coal output and should be extended.

World Directory of Crystallographers

The Philips Laboratories of Irvington-on-Hudson have recently published a "World Directory of Crystallographers" compiled by Dr. W. Parrish. It lists the names, titles, places of graduate study, addresses and fields of interest of 2,260 crystallographers in fifty-four countries; a preface includes a brief statistical analysis of this information. Much credit is due to Dr. Parrish for his initiative and industry in preparing this work, and to Messrs. Philips for their encouragement and generous contribution to editorial and clerical expenses. Inevitably the first edition suffers from omissions and other shortcomings, but it is satisfactory to learn that if support is adequate the Directory will be published at regular intervals by the International Union of Crystallography. Copies may be obtained at a price of 1·50 dollars post paid from Polycrystal Book Service, 84 Livingston Street, Brooklyn 1, New York.

Philips Gas Refrigerating Machine

The new Philips *P.W.* 7000 gas refrigerating machine is now available (cf. *Nature*, 176, 623; 1955). It is a compact, electrically driven, single-cylinder unit, capable of producing five litres of liquid air or liquid nitrogen an hour within 15 min. of starting up. The design of the equipment is unique in that the gas to be liquefied does not undergo compression or pass through any working parts; by this means an exceptionally pure product is assured. The machine will produce liquid gas from those gases which will liquefy at above − 200° C., and temperatures of − 80° C. to − 200° C. can be achieved in a single stage. Under normal conditions, the machine requires only an hour for defrosting and draining of the freezer after 16–20 hr. production. Moisture and carbon dioxide are removed simply by freezing.

Acceleration of Life-cycle of Southern Pine

An important advance in scientific forestry may be marked by experiments at the California Institute of Technology in which the life-cycle of pine trees has been accelerated more than five-fold. In the Earhart Plant Laboratory, seedlings of the southern pine, commercially the most important pulp wood in the United States, have flowered (produced cones) in a period of only two years. In the forest, this process takes 12–15 years. Selected seeds from single trees of the southern pine were planted in the Earhart Laboratory, where various climatic conditions can be reproduced and controlled. Some of the seeds were placed in conditions of continuous summer, so that the seedlings grew rapidly. Some were planted under conditions of alternate winter and summer, so that several yearly growth cycles were completed in each 12-month period. Finally, some of the trees were first grown to large size in continuous summer, then given a long winter period of dormancy before being returned to summer conditions in which they resumed their growth. Two years after the seeds were planted, this third group of trees produced three female flowers, or pine cones. This is believed to be the first deliberate induction of flowering in a pine tree. The fact that cones have been produced in the southern pine in two years instead of the usual 12–15 years means that it may now be possible to hybridize the trees through repeated generations in the time-span of a single human generation. This will greatly speed up the breeding of trees for faster growth, for better wood, for resistance to diseases and pests, and for growth in climates where they do not now grow.

Pink Shrimps and Red Prawns

Since the War, prawns of the genus *Pandalus* have been increasing in commercial importance. Earlier in the century they were scarcely fished, since the major grounds of most species of this genus lie in deep water, but modern boats and tackle have made their exploitation feasible. Recently, two important works on the biology and fishery of species of *Pandalus* have appeared. Both species, like most but not all of the species of Pandaloidea which have been investigated, are protandric hermaphrodites, but whereas in *P. borealis* all individuals apparently reverse sex from male to female (a fact which has been attracting some experimental studies recently), in *P. montagui* (*Fish. Invest.*, Lond., Ser. 2, 21, No. 4; 1957) Mistakidis has shown that there is a proportion, about 30 per cent, which are primary females, showing no sex reversal. *P. montagui* is unusual too in inhabiting, during part of the year, shallow inshore waters, in the Thames Estuary and Morecambe Bay, so that the fishery is of long standing. The fishery for *P. borealis*, on the contrary, is recent and rapidly expanding, and Horsted and Smidt have presented an extensive study of the actual and potential fishery in Greenland waters, with accounts of the natural history of the prawn and of the fishing grounds in Greenland (*Medd. Komm. Havundersøg., Kbh.*, New Ser., 1, No. 11; 1956).

Exhibition of Nature Photography

The Royal Photographic Society's annual autumn Exhibition of Nature Photography will be opened at 16 Princes Gate, London, S.W.7, at 4 p.m. on November 28 by Mr. David Attenborough. It will be open to the public during November 29–December 20 (not Sundays). The Exhibition will consist of prints, transparencies and stereoscopic work, in monochrome and colour. A special feature of this year's Exhibition will be a panel of prints by Mr. Oliver Pike, an honorary Fellow of the Society, who this year has reached his eightieth year and his fiftieth year of membership of the Society. After the London showing, the whole Exhibition is to go to Exeter, where it will be shown during January 6–February 1, in the Royal Albert Memorial Museum.

Plant Breeders' Rights

A JOINT announcement by the agricultural departments in the United Kingdom says that the Committee on Transactions in Seeds, which is inquiring into the rights and remuneration of breeders of new varieties of plants, is prepared to receive written evidence and views on the subject of the inquiry. These should be addressed to the Secretary of the Committee, 1/3 St. Andrew's Place, Regent's Park, London, N.W.1, to reach him before December 31.

University News: Queen's University, Belfast

DR. H. B. HENBEST, reader in organic chemistry at King's College, London, has been appointed to the chair of organic chemistry at the Queen's University, Belfast, in succession to Prof. R. A. Raphael.

London

DR. P. T. MATTHEWS, lecturer in the University of Birmingham, has been appointed to the University readership in applied mathematics tenable at the Imperial College of Science and Technology.

Sheffield

THE following appointments in the University of Sheffield are announced: P. H. Blundell, as director of the Electronic Computation Laboratory; Dr. B. Stevens, as lecturer in physical chemistry; M. S. Clements, as lecturer in civil engineering; Dr. Russell Brown, as lecturer in electrical engineering. The following appointments to fellowships have also been made: C. J. Edmonds, to the Boots research fellowship for work in the Department of Pharmacology and Therapeutics; D. J. Williams, to the C. H. Desch research fellowship in metallurgy; and P. L. Chambers, to the John Stokes research fellowship to be held in the Department of Physiology.

Announcements

MR. E. J. MANN, formerly assistant director of the Commonwealth Bureau of Dairy Science and Technology, has been appointed director of the Bureau. He succeeds Mr. A. W. Marsden, who left the Bureau in July 1957 in order to take up his new appointment as organizing secretary of the Fifteenth International Dairy Congress.

THE Reith Lectures for 1957, entitled "Russia, the Atom and the West", will be given by George F. Kennan, professor of history at the Institute for Advanced Study in Princeton and leading American historian of Soviet Russia. This is the first time the Reith Lectures have dealt with the immediate problems of international relations. The lectures will be broadcast on successive Sunday evenings in the B.B.C. Home Service at 9.15 p.m. The first is on November 10.

A BANQUET to celebrate the golden jubilee of the Royal College of Surgeons of England will be held at Lincoln's Inn Fields, W.C.2, on November 12. H.R.H. the Duke of Edinburgh will be present.

A MEETING, organized jointly by the Acoustics Group of the Physical Society and the North-Eastern Branch of the Institute of Physics, is to be held at Newcastle on Tyne during November 15–16 on the subject of "Flow Noise". Further information can be obtained from the Secretary, Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7.

A SYMPOSIUM on "Vacancies and other Point Defects in Metals and Alloys" is being arranged by the Metals Physics Committee of the Institute of Metals to be held at Harwell during December 9–10. Further information can be obtained from the Secretary, Institute of Metals, 17 Belgrave Square, London, S.W.1.

A TWO-DAY meeting on water pollution in the iron and steel industry will be held by the Iron and Steel Engineers Group at Church House, Westminster, London, S.W.1, during December 11–12. The meeting will be open to all those interested whether they are members of the Iron and Steel Institute or the Iron and Steel Engineers Group or not.

A CONFERENCE on "The Band Theory of Metals and the Structure of the Fermi Surface", organized by the Physical Society, will be held at the Imperial College of Science and Technology, London, during December 19–20. There will be four sessions on: theoretical aspects of the band structure of metals; experimental results related to band structure; experimental examination of the Fermi surface; and the Fermi surface and related topics. There will be a limited amount of accommodation available. Non-members may attend the conference on payment of a fee of one guinea. All inquiries should be addressed to the Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7, marked for the attention of Miss Miles.

A CONFERENCE, organized by the Institute of Fuel, on "Science in the Use of Coal" will be held in Sheffield during April 15–17, 1958. There will be six sessions: "Physics and Chemistry of Coal"; "Coal Preparation and Breakage"; "Coal Carbonization"; "Combustion and Gasification": "Reactivity of Cokes and Chars"; "General Discussion". Brief opening surveys will be presented at the first five sessions. Advance copies of these will be supplied to authors who intend to submit communications. Further information can be obtained from the Secretary, Institute of Fuel, 18 Devonshire Street, Portland Place, London, W.1.

ERRATUM. Dr. K. Mendelssohn writes: "My attention has been directed to the fact that in my article on the Russian Low Temperature Conference (*Nature*, 180, 460; 1957) I omitted to mention that two observers, one from Poland and one from Hungary, had also attended. They were not low temperature physicists but hoped to initiate this type of work in their respective countries. Omitting their presence from the list of foreign visitors may give rise to the misinterpretation that I have considered their countries as parts of the U.S.S.R.".

INTERNATIONAL CO-OPERATION IN MARINE RESEARCH

MARINE science is growing in usefulness and begins to attract more support from international as well as national authorities.

Unesco initiated a Marine Sciences Programme in 1955 with the establishment of an International Advisory Committee on Marine Sciences chosen from countries in all parts of the world to represent all aspects of the subject. The main object of the programme is to cultivate interest in the oceans, particularly in countries where scientists are not being very active about them, and while this work takes shape limited funds are available from time to time to stimulate international or regional co-operation in work likely to increase world interest and to make the early stages of the work more effective.

The advisory committee tries to hold its meetings in countries where there is a small nucleus of marine scientists ready to take advantage of the influx to discuss work being done in the region, and symposia on regional problems are arranged. One of the most direct methods of achieving the educational and cultural aims is to provide visiting lecturers and travelling fellowships. Short courses have been held at suitable laboratories, for example, a three-weeks course in planktology at Nhatrang in 1956, and more ambitious schemes are being planned.

While these plans are taking shape, grants have been made to a number of symposia arranged by organizations such as the Association of Physical Oceanography and the International Council for the Exploration of the Sea on the most prominent topics of the day. They have included symposia on ocean circulation and on the measurement of primary productivity in the ocean. The Association of Physical Oceanography has been granted a useful sum to facilitate participation by Norway in a joint operation with the United Kingdom and United States to develop and use techniques for measuring deep currents in mid-Atlantic Ocean. Another sum is being used to help scientists from Australia, New Zealand and New Caledonia to lay the foundations for a study of the surface currents and water circulation in the south-east Pacific Ocean and the Tasman Sea.

Unesco is also organizing practical study of the feasibility of joint ownership of research vessels by groups of countries. This seems to be the only answer to the growing cost of maintaining ocean-going research ships. Sooner or later it must be done, and the possibility of a trial venture in the Indian Ocean is being explored. Further tasks have been the assembly of advice and material from competent organizations and scientists on the oceanographic problems bearing on sea and ocean disposal of atomic wastes, and a similar assessment of the scientific considerations relating to international laws designed to govern continental shelves.

Unesco is an ideal organization for cultivating enthusiasm in subjects of educational and cultural value, and the liberal study of the oceans is as good a discipline as any. There is no better field in which to promote mixing of ideas and free exchange of views, and the headquarters and area offices of Unesco know how to go about it.

The International Council of Scientific Unions, to which Unesco makes a large annual grant, is just as suitable for advancing research at higher levels. It encourages and co-ordinates activities of the international scientific unions and furthers common effort in subjects inadequately covered by existing arrangements.

The International Council of Scientific Unions has responded to the needs of marine science by setting up a Special Committee on Oceanic Research, which met for the first time in Woods Hole Oceanographic Institution, Woods Hole, Mass., during August 28–30. The following were present: Dr. A. Bruun (Denmark), Dr. G. Böhnecke (Germany), Cdr. R. A. Capurro (Argentina), Dr. G. E. R. Deacon (United Kingdom), Dr. M. N. Hill (United Kingdom), Dr. C. O'D. Iselin (United States), Dr. N. B. Marshall (United Kingdom), Dr. Y. Miyake (Japan), Prof. H. Mosby (Norway), Dr. N. W. Rakestraw (United States), Dr. R. Revelle (United States), Prof. Steemann Nielsen (Denmark) and Prof. L. Zenkevitch (U.S.S.R.). Prof. Y. Le Grand (France) and Dr. N. K. Pannikar (India) were unable to attend. Two days were spent discussing outstanding problems in all aspects of the subject with the purpose of finding which could be most helped by planned co-operation between many countries. Although the Committee sometimes regretted the absence of one specialist or another, it was adequate, with some timely reinforcement from the Woods Hole Laboratory and its wealth of visiting scientists, to make the occasion a memorable one.

The outcome was a general agreement that there is a real need for international collaboration in studying the deep oceans. Theoretical studies and the development of new techniques are likely to succeed well enough in individual laboratories and in co-operative effort between major institutions bordering on common ocean areas and having joint interests, but the task of sending expeditions to distant parts of the ocean, even to areas which promise the best conditions for studying basic problems, becomes increasingly difficult for any country. We know something of every ocean, but there are large fairly blank areas where modern ideas and methods are not likely to be applied until the cost and effort are widely shared.

Among the new techniques which should be used are: (1) measurement of salinity of the deep and bottom waters with the new order of precision made possible by electrical conductivity measurements; (2) direct measurement of the deep currents with free-drifting floats or moored current meters; (3) use of the distribution of naturally occurring radioactive substances as indicators of circulation and mixing; (4) quantitative biological, chemical and physical studies of the sediments; (5) measurement of heat flow from the earth to the water; (6) studies of the carbon dioxide content and the exchanges between ocean and atmosphere. The well-tried methods so far used in biological studies must also be supplemented by recent photographic and acoustic techniques. These and other advances that can be expected during the next few years require the use of ships fitted for deep-sea exploration. This is the most expensive kind of oceanographic research, and an adequate programme is beyond the resources of any one country.

The Special Committee on Oceanic Research judged that the best way to start is to devote the next two or three years to organized attempts by working groups to review the special problems that will be tackled, to widen the acceptance and use of promising techniques and to fill gaps so far as possible. By the end of this preparatory period it should be possible to gather sufficient ship-time and funds together to make a combined assault on one of the least-known and most promising areas. The Indian Ocean was thought to fill this requirement. Its submarine topography and water circulation are not very well known; the complete reversal of wind in two halves of the year affords a unique opportunity for studying how quickly the currents and water layers respond to wind changes, and there is much biological and geological work to be done.

Such a programme cannot be carried out without enthusiastic support of existing national and international organizations, and fairly immediate practical aims must be urged as well as long-term need for better understanding of the oceans. One growing need is for a better appreciation of the effect of using the oceans as a receptacle for the waste products of industry. Even now we need to know what effects the water circulation and the migrations of marine animals are likely to have on the transport of radioactive material deposited in the ocean. We no longer look on the oceans as infinite and readily available sources of food, but we are more and more conscious that better understanding of their physics and biology will be a great help to the successful use of their tapped and untapped resources. The study of climate and weather has also advanced to the stage where it begins to need more understanding of the circulation of heat in the oceans and their interchanges with the atmosphere.

The idea of making a start in the Indian Ocean is likely to receive the approval of most international authorities interested in the oceans. Unesco will have opportunities to arrange the training of scientists from countries around the Indian Ocean, and to make the possibilities known to more countries. The Food and Agriculture Organization is very interested in the striking fluctuations in the fisheries in the northern part of the Ocean, and their effect on the local populations. The scientific unions will recognize the value of new and widespread measurements to basic as well as to the regional problems.

The idea will not go unchallenged. There are not many oceanographers, and they are not likely to welcome new obligations. It was not easy for oceanography to take part in the International Geophysical Year. The scheme that is gradually being formulated is, however, a reasonable plan, with plenty of encouragement for individual effort and inter-laboratory collaboration, as well as measures for promoting co-operation on a larger scale than can be achieved without special organization. The plan is also arranged to take full advantage of the knowledge and experience of existing organizations such as the scientific unions, which are mainly concerned with basic studies of particular aspects of the subject, and the regional associations such as the International Council for the Exploration of the Sea, the Pacific Science Council, and others, which grow in importance but are primarily concerned with regional problems. One of the fears most expressed is that there is too much overlapping between all the new and old interests, and too many conferences. As the subject grows we must work for some unification, but it is only fair to admit that there has been so far no forum in which specialists in all aspects of the subject meet together, and we already see growing enthusiasm and sharing of responsibilities. G. E. R. DEACON

THE TECHNICAL ASSISTANCE BOARD

REPORT FOR 1956

THE annual report of the Technical Assistance Board for 1956* to the Economic and Social Council of the United Nations records that a higher initial earmarking of funds for the participating organizations and the secretariat—up to 97·3 per cent of the approved programme, compared with only 56 and 71 per cent, respectively, in 1954 and 1955—with consequent smoother implementation of the programme, was possible; also that 93 per cent of the programme was delivered to the centres requesting assistance during the year. Of the 25·3 million dollars expended on field operations during 1956, 18 per cent was for the 2,128 fellowships, including study grants awarded, for which 88 countries served as hosts; 13 per cent on equipment and supplies for training and demonstration; and the remaining 69 per cent to finance the 2,346 experts supplied. These experts were drawn from sixty-seven nationalities, and despite difficulties in recruitment in certain specialized fields, this total is 238 higher than in 1955; the professional standard was maintained at a high average level, although there are indications that the Expanded Programme does not offer conditions of service adequate to attract men and women of the quality desired in the absence of idealistic motives.

Technical assistance was provided in fifty-six sovereign States and in forty-seven dependent territories; but soundly based requests for technical assistance greatly exceed in volume the possibilities of meeting them, and the report suggests that even if increased resources become available it may be wise to concentrate on the neediest countries and territories. Some adjustments in the geographical distribution have already been made: in 1954, Viet-Nam, Cambodia, Laos, Sudan, Tunisia, Morocco and Ghana received technical assistance under the Expanded Programme amounting to 240,000 dollars; in 1956 they received 780,000 dollars, and for 1957 it will be about 1·5 million dollars. In many of the less-developed countries, requests for assistance place increasing emphasis on the development of administrative and technical services. The ability of a country to develop its resources and to take full advantage of technical assistance depends largely on the stage of development of its government and administration, and increasing attention is likely to be given to this aspect as the resources of the programme expand.

The Technical Assistance Board is examining the high proportion of continuing projects—915 out of the 1,334 projects in operation in 1956 were started in 1955 or earlier—with reference to the possibility that the programme as a whole is becoming rigid. The continuing programmes accounted for 85 per cent of the expenditure on the field-programme, but this was largely due to the overlapping of programme years, although there are a few genuine long-term projects. Nevertheless, the chapter on evaluation of the programmes introduced this year is intended to be a regular feature of future annual reports, and it is hoped that governments will co-operate in providing the material on which an effective annual review can be based. The number of pledged contributions again increased: for 1956, seventy-seven countries pledged 28·8 million dollars, and for 1957 some eighty countries have already promised about 30·8 million dollars. Nevertheless, as already noted, the financial resources fall far short of what is required to meet the demand, and financial uncertainty still hampers orderly planning. It would be difficult to over-estimate the gain for the Expanded Programme if the Board and Participating Organizations could reasonably count on the expansion of its resources over the next five years to the 50 million dollars a year envisaged.

---

* Annual Report of the Technical Assistance Board for 1956. Pp. 244. (New York: United Nations, 1957.)

In evaluating the programme, the report this year emphasizes the increasing effectiveness of co-ordination between the Expanded Programme and other multilateral and bilateral programmes in the assisted countries, and the recipient countries were also agreed as to the value of the contribution made to their national development, and that had more funds been available the three types of assistance—experts, fellowships and equipment—could have been combined more effectively to produce a better balanced economy. With few exceptions, the international experts proved not only technically competent but able also to acclimatize themselves quickly and to collaborate effectively. Of the 530 fellowship holders in some eighteen countries, all but 6 per cent now occupy positions where their training can be put to effective use; and although many had fairly recently returned, 45 per cent were already occupying positions of greater responsibility. The Board was also satisfied that all the equipment and supplies provided under the Expanded Programme were effectively utilized.

Almost a third of the report, apart from the appendixes, is occupied by accounts of some projects in operation in 1956. Many of these are of real interest to the scientist and technologist, but only a few can be selected to illustrate what is being done. In view of the direct relation between the development of potato blight and the meteorological environment of the growing crops, the Government of Chile requested help from the World Meteorological Organization to apply meteorological science to the control of potato blight in particular and to other problems of agriculture, and an expert from the Meteorological Service of Ireland was assigned to advise the Chilean Government. While the main purpose of the Chilean authorities was to lay the foundations for an advisory service on the application of fungicides, it also sought answers to other questions on the relation between blight and weather conditions and the areas suitable for testing or growing seed potatoes. Partial answers were provided to these questions which can be amplified and confirmed when more complete data on weather and the incidence of disease are available, criteria used in Ireland for detecting and forecasting blight weather proving equally applicable in Chile, and the Chilean authorities are setting up a network of agro-meteorological stations at their agricultural experimental farms.

At the request of the East Africa High Commission a mission of two meteorological experts was appointed to investigate the meteorological factors in the control of the desert locust and advise on the application of meteorological science to that end. Excellent progress is being made in a detailed and critical synoptic analysis of locust events in co-operation with all the meteorological services concerned, as well as in collaboration with the Anti-Locust Research Centre in London. A Unesco mission on arid-zone research at Recife in Brazil has led to many other requests for such assistance, including a geological and hydrogeological study for a dam on the River Paraguay and the creation of a diploma in hydrogeological studies at the Engineering School at Recife. The establishment of a forest research laboratory for the Philippines, assistance in vocational and technical education in Turkey which led to the production of a five-year-plan for the vocational and technical education of men and boys, assistance given to Indian industry in the improvement of efficiency and productivity, the development of civil aviation services in Indonesia, technical as well as legal assistance to civil aviation in Salvador, the eradication of malaria in Mexico and tuberculosis surveys in Africa are other projects briefly described in the report which can only be mentioned.

THE NUFFIELD FOUNDATION

REPORT FOR 1956–57

THE wide range of the projects which the Nuffield Foundation supports is once again illustrated by the twelfth report of the Foundation, which covers the year ended March 31, 1957. The introduction to the report reiterates that the Foundation's aim is to assist promising work which for some reason is not attracting support from elsewhere and, after enumerating various purposes which the policy of the Foundation does not allow it to assist, points out that the Foundation subscribes to the view that the pursuit of new knowledge is as much the duty of a university as is the dissemination of existing knowledge. Accordingly, the Foundation does not feel called to assist the everyday investigational work of a university department.

Of the grants for science in the United Kingdom, those for biological research, which totalled £54,545, included two further grants of £725 and £2,500 to Dr. Dorothy Crowfoot Hodgkin's unit in the Laboratory of Chemical Crystallography, Oxford, for work on X-ray analysis of large molecules; £5,000 in support of work in the Department of Zoology, Liverpool, on the initial causes of mucosal damage in patients with peptic ulcer and on the evolution of mimicry in polymorphic butterflies with a view of showing how much the effect of major genes can be modified as a result of the evolution of a new gene-complex by natural selection; a further grant of £14,000 over five years in support of the two units in the Department of Zoology and Comparative Anatomy, Oxford, working on evolution in wild populations, industrial melanism, analysis of the causation of behaviour (with emphasis on sensory perception prior to learning and on motivation), the survival value of various anti-predator devices and adaptive radiation in evolution; £7,400 over three years in support of Prof. H. E. Street's work at the University College of Swansea on the nutrition and metabolism of excised root cultures; and £2,000 over three years to the University of Durham for work on the hatching mechanism of the potato-root eelworm. The grant towards the work on non-specific immunity at the Lister Institute of Preventive Medicine has been renewed for a further five years at the rate of £3,000 a year. Other grants for scientific research include £1,135 to Dr. N. R. Hanson to enable him to write a book, "The Positron: a Chapter in the History of Ideas", illuminating the interplay of theory and observation at the frontiers of scientific discovery as shown in the discovery of the positive electron, and an additional £2,000 to the Research Laboratory for Archæology, Oxford, towards increases in expenditure during 1956–57.

Of the £125,000 allocated for technology, the largest grant is £3,300 over two years for an investigation—into the effectiveness of existing experiments in removing hindrances to the application of science—which the Science and Industry Committee, formed jointly by the Royal Society of Arts, the British Association and the Nuffield Foundation, now proposes to undertake. Besides a grant of £1,200 over three years towards an investigation into the training of design engineers at the Department of Engineering, Cambridge, another grant of £400 was made to the same Department for a further experimental course to study the application in a different environment of techniques developed for training graduate engineers for junior executive posts and to experiment with a technique of examining the relations within a group of managers, while a grant of £1,000 a year for three years was offered to the Borough Polytechnic for research scholarships in food chemistry.

In the field of medicine, the Foundation, with the help of the Oliver Bird Fund, continued to concentrate its support of research in rheumatism in a few centres where fundamental research is under the direction of men of proved ability. The final results of one long-term chemical trial of cortisone have shown that cortisone is no better than aspirin in the treatment of early rheumatoid arthritis. A grant of £9,595 over three years was offered to the University of London for research on hypnosis by Prof. H. J. Eysenck at the Institute of Psychiatry, and £6,330 over three years for Dr. J. G. L. Williams's investigation at St. Thomas's Hospital Medical School of the possibility of using the measurement of cardiovascular responses in the diagnosis or classification of psychiatric patients and in measuring the efficiency of the therapy they undergo.

A further grant of £1,400 a year over two years was provided for Dr. Honor Smith and her team at the Radcliffe Infirmary, Department of Neurology, Oxford, to study in greater detail the abnormal immunological patterns in disseminated sclerosis, while a grant of £10,000 was made to assist the erection and equipment of a rehabilitation unit for the disabled agricultural worker, consisting of a hostel for twelve patients and a remedial therapy section which provides occupations which the agricultural worker is likely to need. The Foundation is also providing £16,000 to carry the industrial health service being set up at the Central Middlesex Hospital by the North-West Metropolitan Regional Hospital Board through its first three years and has set aside £7,150 over three years in support of Mr. R. H. Hunt Williams's research at the Royal Berkshire Hospital, Reading, on problems of hearing and deafness in early infancy. An offer of £9,000 over three years has been made to the University of Leeds and the United Leeds Hospitals in support of research on problems of screening in diagnostic radiology, including the use of television techniques.

No large grants were made during the year in the social sciences, to which £81,975 was allotted, but special attention is directed to two projects. The first of these is the pilot study being made at Leeds University Library, of how it is used for borrowing by undergraduates and scholars, for which the Foundation has set aside £2,000. It is hoped that something will be learnt of how many titles are required for the undergraduates of a large mixed university and of gaps in the collection, from an examination of loans obtained from other libraries. Some of the material may form the basis of further studies in connexion with the use of the library for research purposes. The second project, which may also lead to further investigation, is into the wilful damage which is being done to social amenities by young people in the new towns. Dr. James Macintosh is in the first place collecting the facts with the ultimate object of suggesting what action might be taken or what further studies are required, and he will also study the methods of education in citizenship of children, adolescents and their parents provided by official and unofficial bodies: the Foundation has allocated £2,350 for the first year of the investigation. A further grant of £3,915 was offered to the Shoreditch project for the revised version of its family service unit to help families which appear to be in danger of breakdown, on condition that the final design of the research is approved by Prof. R. M. Titmus.

The University of Manchester received £2,000 to enable Prof. S. Devons to carry out a pilot experiment with young physicists in part-time university work combined with part-time science teaching at local grammar schools. A grant of £950 to The Queen's University of Belfast was to enable Mrs. J. M. Alexander to continue her study of factors which affect the supply and training of scientists, such as the problem of schoolchildren capable of advanced scientific work, who either leave school early for non-scientific fields or who are directed to arts subjects at an early age, and the difficulties which seem to exist in the full use of women in scientific and technical employment.

The Royal Institute of Public Administration has been assisted in its comparative and critical study of the organization of building construction and maintenance in local authorities with a grant not exceeding £2,250 a year for up to two years. Mr. J. G. G. Wootton's study of the organization and working of the Association of Engineering and Shipbuilding Draughtsmen is being assisted by a grant of £375 over two and a half years, and a grant of £6,000 over three years was made to the University of Leicester in support of an eight-volume agrarian history of England. A brief progress report from the Division for Architectural Studies notes that the team engaged in the study of laboratories has completed its survey into the utilization of space and services and also the studies of daylight conditions in laboratory rooms, made jointly with the Building Research Station; that the first stage of the building programme at the Imperial College of Tropical Agriculture, Trinidad, was designed during 1956; and that the Division is to prepare plans for a small Agricultural Research Council Laboratory at Cambridge.

A grant of £3,000 a year for three years was offered in support of Mr. P. Townsend's study at the London School of Economics and Political Science of the institutional care of old people, and a further £9,000 has been set aside for Prof. K. J. Franklin's work on the ageing effects of ionizing radiation at St. Bartholomew's Hospital Medical College, in continuation of his studies on the physiology of ageing.

The grant to the University of Bristol for field studies on the employment of elderly workers has been renewed for two years at the rate of £3,700 a year.

Among grants for the Commonwealth overseas, which totalled £32,741, may be mentioned a further £800 to the Departments of Anthropology and Anatomy, University of Sydney, in support of the expedition to the Western Highlands of New Guinea; £20,000 over three years to the Central Pedagogical Institute, Allahabad, in support of its work in teaching English; a further £3,500 to enable the Smuts Archive Trust to complete its work; £3,600 over two years to the University of the Orange Free State in support of research on soil organic matter; £1,800 over three years to the Plant Physiological Research Institute, University of Pretoria, for research on amino-acid metabolism and other aspects of the assimilation of nitrogen; £2,450 over three years to the University College of the West Indies for marine biological research; and £8,000 to the Uganda Foundation for the Blind for capital expenditure and maintenance costs over two years of a scheme for the training and employment of the rural blind.

Travel grants included one to enable Dr. L. Guttmann to visit cities in six of the Australian States to advise on the development of spinal centres and on facilities to be provided for vocational training of the physically handicapped.

Only one medical fellowship was awarded in 1956, but the dental fellowships and scholarships scheme continued to attract a high standard of applicant and three fellowships and two scholarships were awarded. The schemes for biological and sociological awards continued unchanged. One bursary in biology was given and one scholarship in sociology. The regulations for the Royal Society and Nuffield Foundation Commonwealth Bursaries have been slightly altered to make it clear that applicants should hold salaried posts to which they will return and that they will draw their salary while away. The Foundation arranged with the Indian and Pakistan Governments to provide two travelling fellowships annually from each country to members of the administrative class of the Civil Service for study in the United Kingdom, but otherwise policy for awards from the Commonwealth countries was unchanged. The scheme for overseas farmers is to be enlarged by an additional award, and with the National Research Council of Canada, the Foundation is to provide travel grants to enable senior lecturers or professors to visit the smaller Canadian universities.

THE DEFENCE STANDARDS LABORATORIES, AUSTRALIA

ANNUAL REPORT

THE broad function of the Defence Standards Laboratories in Australia is the application of scientific knowledge and research within the fields of chemistry, physics, metallurgy and engineering to the problems arising in the design, development, manufacture, inspection, storage and use of defence material. In addition, as the name of the establishment indicates, it is concerned with the maintenance of standards of measurement and of quality, its own being based on the national standards held by the National Standards Laboratory, Sydney, and on the specifications prepared and issued by the Standards Association of Australia. In the annual report of the Laboratories for the year ended June 30, 1956*, an account is given of the general activities of the establishment and of the more important projects and investigations either completed, or in which significant progress was made during the period under review.

Recruitment during the year both in the professional and other staff was not sufficient to maintain strength, and the total staff at Maribyrnong, Victoria, and the two inter-State branches (Alexandria, New South Wales, and Finsbury, South Australia) decreased from 594 to 577, reflecting the general shortage of scientific and technical man-power in Australia. The organization consists of a chief superintendent, Mr. A. E. Dawkins; deputy chief superintendent, Dr. F. A. Fox, appointed in February 1956; and four divisions—materials and explosives, protective chemistry, metallurgy and engineering, and physics.

In the Chemistry Division work was done on the analysis of gases by interference refractometry; the determination of small quantities (of the order of two micrograms) of acetone in air; the determination of oxygen and nitrogen in metals and alloys and the recrystallization of barium sulphate. New forms of titanium esters were developed for use in paints, and standard soils for the testing of dishwashing detergents and for metal-cleaning preparations were investigated. In biochemistry a study was made of the organophosphorus compounds which are used as insecticides and plasticizers and in medicine.

The Metallurgy Division was mainly concerned with the production and processing of pure chromium and chromium alloys. Investigations of their properties and structure were largely confined to attempts to elucidate the nature and cause of the lack of ductility of the chromium-base alloys at room temperature. A study was commenced of the embrittlement of the metastable beta-phase alloys of titanium. Other investigations included the lost wax process, corrosion problems associated with iron and steel in cooling waters, cadmium plating, and lead in chromic acid.

The diverse activities of the Physics Division covered the fields of chemical physics, radiological physics, metrology and temperature measurement. Improvements were made to the microwave spectroscope and nuclear spectrometer parts were constructed and tested. The new technique of microwave observation of detonation announced in the 1954–55 annual report was further improved. An apparatus was devised which enables the thermal conductivity of gases and vapours to be determined from the equilibrium temperature attained by a platinum spiral immersed in the fluid, and measurements were made on pure gases and on binary mixtures. In connexion with the study of the accuracy and reproducibility of temperature measurement at the triple point of water, the performance of the Laboratories' Smith resistance thermometry bridge was improved by the use of a stable decade resistor for calibration purposes. A new type of multi-cell inert dry battery composed of ordinary cells made inert by dehydration under heat and vacuum was developed and this is discussed in some detail in the annual report.

Various other miscellaneous investigations included research on xerography; the effects of climates in different parts of Australia on the durability of paint.

---

* Annual Report of the Defence Standards Laboratories for the year ended 30th June, 1956. Pp. iv+44. (Maribyrnong, Victoria: Defence Standards Laboratories, 1957.)

films; the priming of wood; the weathering of textiles; viscometry; and mathematical studies. The report concludes with lists of the various personnel and their status, the numerous publications by members of the staff of the Laboratories and the names of the various governmental and other committees on which the establishment has been represented.

GEOGRAPHY IN JAPAN

THE International Geographical Union normally sponsors a World Congress every four years, the last two being held at Rio de Janeiro (1956) and Washington (1952). Although much scientific work is being carried on continually through a series of a dozen Commissions, the Executive tried the experiment of holding a Regional Conference of more limited scope than a main Congress, and with a definite field of work. Following the success of the first such Regional Conference on Africa at Makerere in 1955, the Executive gave its support to the proposal of the Japanese National Geographical Committee under the chairmanship of Prof. Fumio Tada (University of Tokyo) that it should organize a Regional Conference in Japan. The Conference was held during August 28–September 3, with the support of the Science Council of Japan and of numerous universities and municipalities at Tokyo and Nara. The programme, which also included a symposium on South-East Asia and a range of papers in nine sections, centred on the problems of monsoon Asia in general, and Japan in particular, and afforded to the eighty delegates from overseas an opportunity of seeing and appreciating the work of Japanese geographers.

The Conference was preceded by two long excursions, to Hokkaido and northern Honshu, and followed by three others to central and western Japan. The substantial guide books prepared for these excursions were arranged to form a complete regional geography of Japan which, together with a summary volume, afforded the first geographical description of Japan in English written entirely by Japanese authors. Although summaries of original papers in Japanese have long been added in a Western European language (in recent years usually in English), the main work of Japanese geographers has remained little known to Western workers. A comprehensive exhibition of the maps published officially by the Geographical Survey Institute under the direction of Akira Watanabe (one of the secretaries of the Conference) showed examples not only of the large range of geographical and geological maps, but also of many specialized cartographical experiments which have scarcely been seen outside Japan, including a number still in manuscript. The delicacy of old Japanese art is reflected in the many beautiful examples of modern map production and printing. In a country where pressure of population on limited land resources is so extreme that each acre of cultivated land must support six or seven persons in food, it is natural that special attention should be paid to the accurate portrayal of land forms and land use.

In particular, Japan has accepted the principle that to map accurately the existing use or non-use of land is an essential prelude both to understanding the present position and to planning for the future. By mid-1957 no less than 300 sheets on the scale of 1 : 50,000 of the land use map had been completed —roughly a third of the whole country excluding Hokkaido. This work is financed in the main by the prefectural governments, and the maps, undoubtedly the finest and most detailed produced anywhere in the world, have not been placed on public sale. The classification of land use follows the scheme advocated by the World Land Use Survey and Commission of the International Geographical Union, but with many refinements to meet local conditions. In a country primarily dependent upon rice, there is an important distinction between paddy lands and land for other crops; the determining factor both in this case and in other forms of land use is often degree of slope. Accordingly, experimental maps have been produced, also on the scale of 1 : 50,000, of slope, land-form and valley-density. The slope map displays seven categories of slopes ranging from more than 40 deg. to less than 3 deg. The valley-density maps shows valleys revealed by air photographs to be suffering from gullying and degradation, and records the number of such valleys per square kilometre. The land-form classification map is an ambitious attempt, combining a classification based primarily on different types of hill lands, uplands and terraces and lowlands with a symbolic representation of surface geology and a scheme of minor physiographical regions. An explanation published (in English) in the *Bulletin* of the Institute in March 1955 urges that such work must precede soil surveys as understood in other countries and of which Japan has published also one experimental sheet (1953). The dependence of Japan for protein on fish has led to much attention being given to the mapping of details of the sea floor and of marine deposits around the islands. The numerous other fields of original study were well shown in the 130 papers contributed to the nine working sections.

A volume of abstracts was printed in advance, and it is planned to publish a comprehensive report of the Conference. Among the foreign participants were the president of the International Geographical Union, Prof. Hans Ahlmann (Sweden), the two immediate past-presidents, Prof. L. Dudley Stamp (United Kingdom) and Prof. G. B. Cressey (United States), the secretary-treasurer, Prof. Hans H. Boesch (Switzerland), and the past vice-president, Prof. G. Kuriyan (India).

L. DUDLEY STAMP

MAKING AND BREAKING POLYMER MOLECULES

RECENT advances in polymer chemistry of especial current interest were reviewed under the title "Making and Breaking Polymer Molecules" at the second session of Section B (Chemistry) of the British Association held in Dublin on September 9. At the invitation of Dr. J. W. Cook, president of the Section, Prof. C. Kemball took the chair and introduced the following contributions: "The Mechanico-chemistry of Polymers", by Dr. L. Bateman (British Rubber Producers' Research Association); "Stereospecific Polymerizations", by Prof. H. F. Mark (Polytechnic Institute of Brooklyn); "Synthetic Polypeptides as Models for Natural Proteins", by Dr. C. H. Bamford (Courtaulds, Ltd., Maidenhead); and "Plastics for Use; Designing Molecules for Particular Purposes", by Dr. C. W. Bunn (Imperial Chemical Industries, Plastics Division).

In some introductory remarks, Dr. Bateman noted that the present familiarity with rubbers, plastics, and fibres and with the essential part they play in everyday life tends to obscure the fact that they are largely products of the twentieth century and quite considerably of the past twenty years. Rubber production, for example, increased from 29,000 tons (all natural) in 1900 to 2,900,000 tons (35 per cent synthetic) in 1955, and rayon showed a still greater proportionate increase (from 1,000 to 2,200,000 tons). Even wool, which as an age-old natural fibre might be regarded as an exception to that generalization, increased in usage from 740,000 to 2,200,000 tons in the period stated. Polyvinyl chloride and nylon, two examples of wholly synthetic materials, were scarcely known in 1935 but were produced to the extent of 630,000 and 113,000 tons respectively in 1955. The scientific basis of the remarkable growth thus illustrated is two-fold: increasing mastery of the transformation of simple compounds into large and complex molecules similar to those of natural origin, and more efficient and extensive adaptation of these polymeric substances, natural and synthetic, to practical purposes. The overall result has been less the replacement of the natural by the synthetic materials, as is often supposed, than mutual augmentation to satisfy a rapidly expanding world demand.

Turning to the main subject of his address, Dr. Bateman pointed out that solid polymers are invariably subject to mechanical treatment during their processing from the raw state into finished products. Grinding, mixing, and extruding typify such treatments, which are generally looked upon as purely utilitarian procedures of little or no chemical significance. However, studies of the mastication of rubber—a basic process in the rubber industry—have recently shown that chemical reactions similar to types encountered conventionally are involved. A new branch of polymer chemistry—the mechanicochemistry of polymers—can be recognized, with many theoretical and practical ramifications. Common mechanical treatments of polymers can be looked at afresh and their purpose and practice more critically appraised, and the making and modifying of polymers can be approached in an entirely new way.

The breakdown of rubber on mastication normally requires the presence of oxygen and is peculiar in proceeding more readily at temperatures both above and below about 110° C. W. F. Watson first clearly recognized that this behaviour is due to two distinct mechanisms of breakdown. One mechanism, dominant above about 110° C., involves direct interaction of oxygen with the rubber, which is known to take place at these temperatures and to lead to molecular scission; the other, dominant at lower temperatures, is a mechanically promoted reaction in which the primary act is the literal tearing apart of polymer molecules into free radicals, the oxygen participating afterwards to prevent recombination of these fragments. Distinctive of this second mechanism is the negative temperature coefficient, which arises from the increase in bulk viscosity as the rubber is cooled, causing the applied force to be utilized more in shearing molecules than in merely displacing them.

This basic picture enables other diverse features of the mastication process to be correlated, and also suggests possibilities for utilizing mechanically generated free radicals for synthetic purposes. Thus, if two polymers are suitably masticated together then cross-combination of the radical fragments so formed can give a block co-polymer. Similar products can be obtained by masticating a polymer with a polymerizable monomer, the free radicals generated from the former initiating polymerization of the latter. This reaction is readily realized in practice and is extremely versatile. Monomers of different chemical and physical type can be employed with a variety of base polymers—plastics, polycondensates such as nylon, and natural carbohydrate and protein polymers can be used as well as rubbers. The reaction conditions are very simple—the reactants have not to be brought into a solution or emulsion, no catalyst or other ingredients need to be added, and no recovery procedure is required to isolate the product. Provided the base polymer can be suitably sheared—and this is the critical factor—high conversions of many monomers can be obtained in the space of minutes at room temperature. A demonstration of such a reaction was given on a laboratory masticating machine specially designed for this purpose.

Prof. Mark began his address by observing that the plastics industry has developed on the basis of an understanding of addition polymerization, which proceeds by a chain process comprising three stages: an initiation step in which a vinyl monomer is converted into a highly reactive intermediate; a propagation step in which the polymer chain is extensively built up from the primary intermediate, and a termination step in which polymer growth is stopped by conversion of active intermediates into inactive molecules. Control of the overall reaction has hitherto been restricted, however, to the first and last of these steps, with two important consequences. First, certain simple vinyl compounds such as ethylene and its alkyl derivatives have either not been polymerized or have only responded to abnormally vigorous conditions; secondly, the addition of each monomer unit to the growing polymer chain has proceeded randomly with little regard to any structural or stereochemical pattern.

It might be expected *a priori* that control of the propagation step would require the reactive locus of the growing polymer, whether free radical or ionic, to be complexed so as to confer more highly selective reactivity both dynamically and stereochemically. The new class of polymerization catalysts, recently discovered by Ziegler and extensively exploited by Natta and others, would appear to function essentially in this manner.

These last outstandingly important developments stem from Ziegler's observations that a very limited degree of polymerization of ethylene at room temperature and pressure induced by certain metal alkyls can be remarkably enhanced by certain metal halides, notably of titanium, to yield a polyethylene of high molecular weight. Not only are the reaction conditions so different from the high-pressure process developed by Imperial Chemical Industries, but the product also differs from commercial polythene in being harder and of considerably higher softening point—now known to be due to its more regular linear structure.

The high activity of Ziegler catalysts and the stereochemical control they exert on polymer synthesis are strikingly apparent with substituted ethylenes. Alkylethylenes hitherto resistant to extensive polymerization have been converted into high polymers, in many cases with the substituent groups strictly oriented with respect to each other along the polymethylene chain. Several such hydrocarbon polymers, in which the molecular configuration results in compact structures showing high crystallinity, have melting points above 300° C. Butadiene and isoprene also polymerize easily under similar conditions, and by subtle changes in catalyst composition 1 : 2- and 1 : 4- attachment can be selectively promoted, in the latter case to give either the *cis* or *trans* forms. The different isomers have been isolated in fairly high states of purity, the essential constituents of natural rubber and gutta-percha (*cis*- and *trans*-polyisoprenes) being synthesized in this way.

Prof. Mark concluded by referring to the immense impact of this work. Industry had responded vigorously to the potentialities of using some of the cheapest and most abundant organic compounds as sources of polymers, with technical qualities promising to make them formidable competitors to established materials. Large-scale plants for producing some of these new polymers are already on the point of coming into operation. At the same time, the singular achievement of effecting polymerization with a stereospecificity comparable to natural processes has greatly stimulated further research. New types of stereospecific catalysts are being discovered and their range of applicability steadily widened.

In the third paper, Dr. Bamford first explained that the complexity in number and type of the amino-acid units in proteins not only makes it extremely difficult to determine the details of protein structure—so difficult in fact that this has only been achieved for one relatively simple protein, insulin—but impedes correlation of the properties of proteins with specific molecular features. For this latter purpose, synthetic polypeptides derived from one amino-acid are valuable model compounds, since they simulate proteins in essential structural and functional character and yet possess polymeric symmetry which permits various physical measurements to be more decisively interpreted.

After referring to the preparation of high-molecular weight polypeptides by polycondensation of *N*-carboxy-α-amino-acid anhydrides, Dr. Bamford went on to describe their main structural features and especially how these had been investigated by modern physical techniques.

Polypeptides synthesized from single amino-acids such as L-alanine and γ-methyl-L-glutamate behave like some proteins (such as hair keratin) in existing in two inter-convertible forms. In the α-form the molecular chains are folded and coiled into a helix which models show to form a compact, closely packed structure. In the other (β) form, the molecules are extended linearly with the chain atoms forming a nearly planar zig-zag. These two forms give different X-ray diffraction patterns, from which, for example, the dimensions of the helix and the number of amino-acid units per turn can be determined. Detailed structural information has also been obtained by the use of polarized infra-red spectroscopy, which permits the directions of certain bonds in the molecule to be ascertained with respect to the molecular axis. In the α-form of polypeptides the C=O and N—H bonds are found to be parallel, and in the β-form to be perpendicular, to the axis. It can therefore be deduced that an important, indeed essential, feature of the helical structure is a series of hydrogen-bonding 'struts' between groups on neighbouring turns of the helix. In the β-form, however, hydrogen bonding occurs between imino and carbonyl groups in different molecules. This difference of *intra*- and *inter*-molecular bonding is understandably reflected in physicochemical behaviour, as was demonstrated in a simple experiment. The α-form of a polypeptide was rapidly swollen and eventually dissolved by benzene, which had little effect on the β-form, the macrostructure of which is preserved by the extensive polar network. The denaturation and insolubilization of proteins are accompanied by a partial transformation of folded into extended chains, and the nature of this phenomenon has been clarified by work with the synthetic polymers. Silk provides a striking example ; a cast film of silk fibroin in the molecularly folded form was shown to be readily soluble in water, whereas the ordinary (β) form is, of course, insoluble. An example of a polypeptide which 'denatures' on heating in water (poly-DL-alanine) was also demonstrated.

The study of chain configurations in solution by optical rotation measurements was next described. This technique depends on the fact that a helical polypeptide chain itself gives rise to optical activity which may be reinforced or opposed by asymmetric carbon atoms present, and has already given interesting information about the interaction of polypeptides and proteins with solvents of different types.

Finally, the 'kinetic chain effect', in which a polypeptide appears to simulate enzyme action, was mentioned ; this raises the possibility that polypeptides may be useful models for kinetic as well as structural studies.

In presenting the final paper, Dr. Bunn said he wished to emphasize that all the important synthetic polymers so far produced had been discovered by accident or by acute empiricism rather than design, and this approach would certainly continue as a major path of progress. However, the principle of trial and error is becoming more laborious and expensive to apply comprehensively as the possibilities for synthesis continue to multiply, and rational guidance on how to make polymers of given properties will play an increasing part in deciding the main lines to follow. To a considerable extent this is happening to-day, and many qualities of a new polymer can be predicted fairly precisely.

A fundamental difficulty in designing a polymer for a given application is that not one single property is involved, but a number of interdependent properties some of which are mutually antagonistic. The problem, therefore, is to select the most advantageous balance of properties, and this is not easy to do *a priori*, first because the resultant effect of properties considered singly is complex and secondly because the conditions of service may not be directly related to measurable properties of the material.

The bulk properties of polymers may be considered in terms of three fundamental factors : (1) intermolecular interaction ; (2) molecular flexibility ; and (3) crystallization. The influence of the first is well known qualitatively : in non-polar substances such as hydrocarbons, intermolecular attraction is weak, the molecules can readily move past one another, and such polymers will be soft and prone to flow on deformation ; as polar groups which give rise to stronger attractive forces (for example, OH, Cl, CO_2R, CN) are introduced, so the polymer will become harder and more rigid. The second factor is associated with the ease of rotation of segments of the molecule about bonds in the chain. This is partly controlled by steric effects, and partly by more deep-seated effects associated with bonding electrons. Exactly how these determine molecular flexibility is still uncertain, but it is now recognized which groupings confer flexibility and which rigidity. An interesting feature is that certain unsaturated hydrocarbon polymers (*cis*-polybutadiene and natural rubber) are more rubbery than a simple saturated hydrocarbon such as polyethylene, despite the fact that rotation about double bonds is highly restricted and might be expected to increase stiffness. This apparent anomaly reflects, however, the extra flexibility of C—C bonds adjacent to double bonds which more than compensates for the rigidity of the latter. The third factor, crystallization, depends on the detailed nature and regularity of polymer structure and also on physical conditions. No high polymer is wholly crystalline, but certain fibres are nearly so; natural rubber, which is amorphous when unextended, owes its strength to the considerable degree of crystallization which develops on stretching to breaking point. Crystallization is a particular and powerful form of intermolecular interaction and therefore parallels the first factor considered in producing stiffness and hardness and especially strength. It is important to remember that all these factors are dependent upon temperature—as must be borne in mind in any classification of a substance as a rubber, plastic, or fibre. Working conditions 100 deg. C. hotter or cooler than conventional temperatures call for major changes in the usual designations.

Dr. Bunn then proceeded to illustrate how knowledge of this kind can be applied and how variations in the above factors can be traced systematically. Some effects of modifying linear chains with 'branches', of cross-linking, and of co-polymerizing different monomers in different proportions were described. Attention was directed to the 'non-additivity' of the properties of co-polymers with respect to the individual components owing to the complex interplay of the structural factors. This is apparent even in the simplest hydrocarbon systems, where a co-polymer of ethylene and propylene, being non-crystalline, is a soft, rubbery material very different from crystalline polyethylene and polypropylene, which are quite hard and rigid plastics.

L. Bateman

PSYCHOLOGICAL AND OCCUPATIONAL ASPECTS OF AGEING

THE aim of the symposium on ageing arranged at the Dublin meeting of the British Association by Section J (Psychology) on September 5 was to present a sample of the work being done in Great Britain by psychologists and sociologists. Prof. L. S. Hearnshaw (professor of psychology in the University of Liverpool and honorary director of the Medical Research Council group for research on occupational aspects of ageing) was in the chair, and in his introductory remarks gave a brief historical sketch of the development of research into the psychology of ageing in Great Britain, and an outline of the work in progress at the Medical Research Council group at Liverpool. Prof. Hearnshaw referred to the presidential address, delivered to Section J by Dr. Wynn Jones at the Norwich meeting of the British Association in 1935, on "Personality and Age", which was the first contribution to the subject by a psychologist in Britain; to the work of the Nuffield Foundation; and in particular to that of the Cambridge unit directed by Mr. A. T. Welford during 1946–56. The rising interest in ageing was a natural outcome of the changing age-structure of the population. Not only is the number of persons over sixty-five increasing, but the proportion of the working force between fifty and sixty years of age is also rising. Research must be directed, therefore, not only to the study of old age, but also to the process of ageing from middle life onwards.

Prof. Hearnshaw concluded with a brief progress report on the main lines of work of the Medical Research Council group in Liverpool, which is concerning itself with three matters in the first instance. First, it is attempting to get reliable information, which at present, surprisingly, does not seem to exist, on changes in the main sensory modalities with age. Work is at present in progress on hearing. It is hoped to establish norms of deterioration with age, and to throw light on the effects of such deterioration for general psychological and occupational adjustment. Secondly, the group is concerning itself with those problems included under the general heading of 'rigidity'. There is a certain amount of miscellaneous evidence, partly anecdotal, on the increasing rigidity and lack of flexibility in the ageing person; but the psychological processes remain obscure, and their elucidation seems to be of both theoretical and practical importance. Thirdly, the group is concerned with industrial studies of ageing with especial reference to the attitudes of the ageing person himself and of others towards him.

D. B. Bromley (Liverpool) followed, with an account of his investigations on the effects of age on intellectual processes. Lehmann in the United States has demonstrated that the peak years for creative intellectual output are in the age-range 30–35, that thereafter output decreases faster for quality than for quantity, and that very high-grade intellectual achievement falls most rapidly of all. In Bromley's experiments various tests of intellectual performance were administered to 256 subjects, ranging in age from the twenties to the eighties and forming three matched age-groups with mean ages of approximately 27, 47 and 67 years, respectively. The results were broadly in agreement with Lehmann's conclusions. High-grade intellectual output appears to decline with age, unlike low-grade output (namely, illogical, bizarre or other types of erroneous response), which shows a relative increase. Not only do older people tend to have fewer good ideas, but they also show a diminution of critical capacity and are less able to judge the value of the ideas they do have. Though capable of reproducing acquired knowledge and skills fairly satisfactorily, the older person is inferior in tasks involving new learning, speed of response, and complex material. There is also a decline in 'incidental memory' or 'latent learning', that is, memory for details incidental to and not required by the main task in hand. Bromley suggested that this finding, if valid, might be of some significance, since a great many advances in scientific research had been made as a result of incidental observations. One of the reasons why older people make fewer outstanding and original contributions to intellectual achievement may be that their capacity for benefiting from incidental experiences is reduced.

Bromley ended his paper with a word of caution. He pointed out that the conclusions reached by psychologists investigating adult intelligence are at best only poor approximations; the tests used are not wholly reliable nor altogether suitable for the purposes to which they have been put; and theories and explanations at present scarcely more than guesswork. Nor are the practical consequences of the findings at all easy to appraise.

The second speaker, S. Griew (Bristol), reported on some recent findings on age and industrial performance obtained by the Unit for Research on Employment of Older Workers, a team which is financed by the Nuffield Foundation. Analysis of the age structure of the workers in a number of light engineering firms showed a remarkable degree of agreement between the rankings of jobs by age, both between different firms and between two different periods (1947 and 1955) in the same firm. There seemed to be a tendency for jobs manned by workers of a certain age in one firm to be manned by workers of a similar age in other firms. Some of the findings of the investigation ran counter to generally accepted views. Thus it is commonly believed that older workers tend to be engaged in non-productive processes, such as work in the tool-room and maintenance. In fact, however, men in these jobs proved to be no older and in some cases significantly younger than those on production work.

The main purpose of the investigations now in hand at Bristol is to determine what is responsible for the differences in average age on various jobs. The unit is following up about 450 men who have required changes of job, trying to discover the reasons for their wishing to change. Secondly, it is comparing the views of younger (20–30 years) and older (45–55 years) men on their work, their equipment and their firms. Thirdly, samples of work being undertaken by older and younger groups are being subjected to detailed analysis.

Griew referred to a number of points that have already emerged from these investigations. The amount of bodily activity in which younger workers engage is significantly higher than that in which older workers engage, and this applied irrespective of the 'load' of the job. The amount of attention paid visually by older workers to their work seemed to be substantially lower than that paid by younger workers. Another finding, rather hard at present to interpret, is that in the case of older machinists the ratio of the numbers of controls used to the total number present on the machine is invariably higher. He concluded by urging the importance of a sound theoretical foundation for research into the occupational aspects of ageing.

The third speaker in the symposium, C. Fleming (Sheffield), was unfortunately prevented by illness from reading his paper in Dublin. He was to have surveyed community attitudes to population ageing in Great Britain, and the gaps in the present plans for research. In Great Britain attention is still on 'old age' rather than on 'ageing'. Hospitals have developed geriatric services and there has been an increased provision of voluntary and statutory social services for the aged, but preventive geriatrics and constructive medicine are still in an early stage. Research on ageing is still fragmentary and unco-ordinated, and there has as yet been little contribution from sociology, social medicine, and economics. Education for ageing has been lacking in Great Britain in comparison with the United States. There is need for adequate organization in Great Britain for promoting research and community education on ageing. An institute of gerontology, suitably constituted and financed, would facilitate contributions from all disciplines involved. L. S. HEARNSHAW

BIOGEOGRAPHICAL SIGNIFICANCE OF ANEITYUM ISLAND, NEW HEBRIDES

By Miss L. E. CHEESMAN, O.B.E.

Department of Entomology, British Museum (Natural History), London, S.W.7

ANEITYUM, southernmost of the New Hebrides Archipelago, is a small island, about nine and a half miles wide and seven miles long. It is accounted of no economic importance to the Condominium, but is of exceptional value to taxonomists owing to its position between the ancient land of New Caledonia to the west and other Pacific islands to the east. Thus it constitutes a link for those who study the dispersal of species in that region.

Erromango, Tanna and Aneityum, the three southern islands, presumably formed one land-mass in the past, and that this was connected with New Caledonia is evidenced by their Australasian flora and fauna. This refers particularly to Erromango and Aneityum, because Tanna has been subjected to severe volcanic disturbance, and the plants and insects are comparatively uninteresting. There is an active volcano on Tanna to-day. Aneityum is also volcanic but possesses a far richer fauna and flora, suggesting the permanence of older land. There is a Papuasian element in the southern group attributable to a connexion with the northern group during the folding movements of the Miocene–Pliocene Periods. The northern islands, on the contrary, are basically Papuasian with an Australasian element due to that same interchange of species. There exists in that archipelago, therefore, a zoo-geographical line analogous to Wallace's Line, and similarly not sharply defined. Aneityum is the crossroads of two distinct trends of migration.

It is an advantage to taxonomists to recognize this line because Pacific species can be traced back to the country of their origin, via the northern New Hebrides and the Solomon Islands to New Guinea in one direction, and via the southern New Hebrides and New Caledonia to Australia in the other.

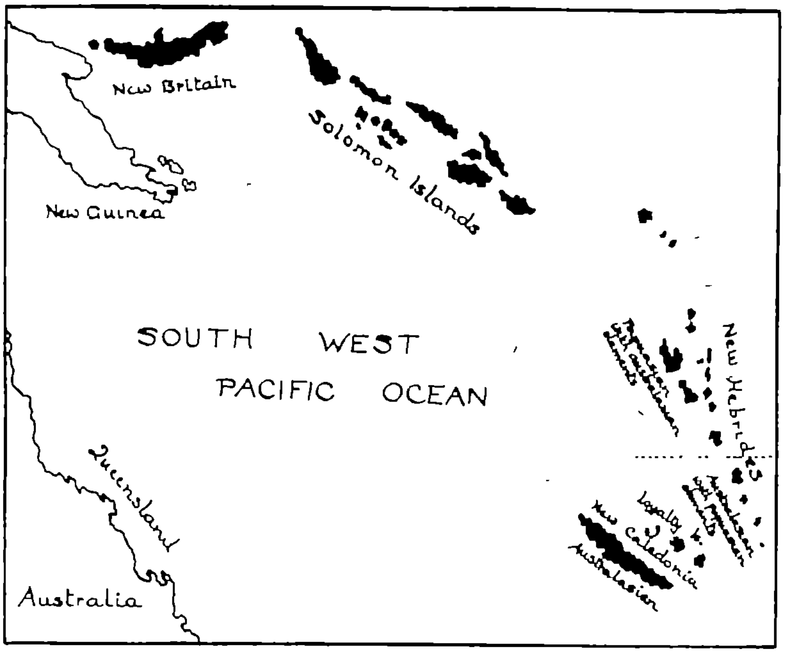

Fig. 1

other groups has been systematically studied, but already we have here a working hypothesis.

The very peculiar forms of New Caledonia, including two endemic families of plants and one endemic family of birds, the *kagy*, are neo-endemic, due to isolation of old land over a long period. These would not be expected to occur outside that island.

We thus find most interesting support biologically for palæogeologists who postulate the first fracture in this eastern section of the Australian shelf as having separated New Caledonia from Queensland during the late Cretaceous Period. Biological evidence suggests that the existing land-mass then included the southern islands of the New Hebrides, until further dislocation took place with subsidence of land throughout the late Miocene and early Pliocene Periods, which isolated New Caledonia and formed the New Hebrides Archipelago.

Botanists have established the close affinity between the flora of the southern group and that of New Caledonia. Species which had been considered endemic to the latter are now known to occur on the former, including *Araucaria columnaris* Forster (= *cookii* Br.), nine other flowering plants and seven species of ferns. My collections made on Aneityum have added eleven species of insects derived from Australia which are either conspecific with those of New Caledonia or are island races. The list will doubtless be augmented when the distribution of

It must not be ignored with regard to the Papuasian forms which are present on the southern islands that these can derive from New Guinea either via the northern group or from tropical Queensland—which is also Papuasian owing to former land bridges—via New Caledonia. Expert knowledge of any particular zoological group can differentiate between species belonging to these two migrations. But if the colonization of islands could be considered due mainly to adventitious means of introduction, there would not exist such distinct faunal areas.

INTERACTION BETWEEN ORGANIC HYDROXY ACIDS AND SILICIC AND GERMANIC ACIDS IN AQUEOUS SOLUTIONS

By E. R. CLARK and J. A. WADDAMS

Department of Applied Science, Wolverhampton and Staffordshire College of Technology

DURING recent years, much work has been carried out in European and American laboratories on the etiology of silicosis. One result of these studies has been the accumulation of an increasing number of observations which are opposed to the formerly widely held solubility theory of silicosis[1,2]. It is maintained by those supporting this theory that silicic acids dissolved from inhaled siliceous dusts are responsible for the initiation of fibrosis in this disease. The presumed biochemical processes underlying this action have been speculated upon in a few cases, but very little experimental work has been carried out on the postulated reactions.

Exploratory work on possible reactions of biochemical significance between silicic acid and α-amino-acids, hydroxy acids, etc., was initiated in these laboratories some time ago. Considerable experimental difficulties were encountered in this work, to which reference is made later. More recently, we have made parallel studies on germanic acid derived from the crystallographic modification of germanium dioxide isomorphous with quartz in the hope of throwing light on the less tractable systems containing silicic acids. This work has utilized solubility, conductimetric, polarimetric, *p*H and viscosity measurements to follow the interactions occurring between germanic acid in aqueous solution and a wide range of hydroxy acids. The formation of a number of definite stoichiometric complexes has been revealed in these systems. The more important of these are summarized in Table 1.

No evidence of complex formation was found using tropic acid, diglycollic acid, glyceric acid, ascorbic acid, and γ-hydroxybutyric acid.

Of the complexes recorded in Table 1, only those derived from tartaric acid have previously been reported. G. V. R. Mattock[3] studied the reactions of tartaric, malic and succinic acids with solutions of germanium dioxide and described the 1 : 1 and 1 : 2 germanotartrates for the first time.

Mlle. O. Vartapetian and M. A. Tchakirian[4] also demonstrated the formation of the 1 : 1 germanotartrate complex by *p*H, conductivity and optical activity studies.

Diagrams illustrating the kind of results obtained in the work here reported are shown in Figs. 1–3. In each case the curves show the results obtained (*a*) in the presence of germanium dioxide and (*b*) in its absence. These curves were obtained using gluconic acid, but essentially similar plots were given by each of the substances in Table 1.

In certain cases it is possible to separate the complexes recorded in Table 1 in crystalline form. That formed between germanic acid and mandelic acid has been obtained in a pure form and has been shown to give an X-ray diffraction diagram markedly different from those yielded by the parent materials.

+ Qualitative evidence only. The specific rotation of *l*-malic acid is too low to give conclusive results.

Potentiometric titration of the aqueous solutions of the complexes with sodium hydroxide solution indicates that all the carboxylic acid groups of the original acid are not available for neutralization in the complex. It would therefore seem that hydroxyl and carboxylic acid groups are involved in the formation of these complexes.

Further studies on the structures of these substances and the possibility of producing insoluble salts of the complexes with bases such as procaine, quinine, etc., are in hand.

The investigation of the possible formation of related complexes involving silicon in place of germanium is rendered difficult, first because of the extremely low conductivity of solutions of pure monosilicic acid, and secondly because one must work at a concentration below that at which polymerization of this substance occurs. This limit has been shown in these laboratories[5] to be equivalent to 13–15 mgm. silica per 100 ml. An extremely sensitive a.c. bridge method using a cathode-ray oscilloscope for the determination of the balance point has been used which is capable of detecting conductivity changes smaller than those to be anticipated in complex formation. Using monosilicic acid prepared in a variety of ways, no evidence of complex formation between this substance and the hydroxy acids examined could be obtained. Negative results were also obtained in polarimetric studies.

It must therefore be concluded that silicic acid does not yield the type of complexes to which its germanium analogue gives rise even at concentrations appreciably higher than those encountered in the tissue fluids of the silicotic lung.

STRUCTURE OF SMOOTH MUSCLES

By Dr. JEAN HANSON and Dr. J. LOWY

Medical Research Council Biophysics Research Unit, and Wheatstone Physics Laboratory,
King's College, London

DURING the past few years, it has become possible to analyse the structure of muscle fibres in sufficient detail to obtain a picture of the behaviour of their submicroscopic protein filaments during contraction. The methods which have made this feasible have been applied almost exclusively to cross-striated muscles. In order to understand the mechanism of contraction, it will be essential to analyse in similar detail the structure of fibres which lack striations and are perhaps less specialized. Material with outstanding advantages for this purpose is available in the smooth muscles of molluscs. A comparative study is being made of these and other smooth muscles, and in this account we shall summarize some recent results and describe in rather more detail a particular type of fibre where the myofibrils are helical and consist of two kinds of cross-linked filaments resembling those found in cross-striated muscles.

Methods

It is well known that smooth muscle fibres are very thin: none that we have examined measures more than about 10μ across. Intact isolated fibres can therefore be studied with the highest resolving power of the phase-contrast microscope; the images seen are very helpful for the interpretation of electron micrographs.

The structure of fibres at various lengths has been investigated in a phase-contrast microscope with an objective of *N.A.* 1·3. The fibres were isolated by teasing from muscles which had been stabilized at defined lengths either by glycerol extraction (using a modification[1] of Szent-Györgyi's technique) or by fixation in 5 per cent formaldehyde buffered at *p*H 7·0. The structural changes during contraction were also followed in glycerol-extracted fibres (suspended in 0·1 *M* potassium chloride, 10^{-3} *M* magnesium chloride, *p*H 7·0) under the microscope while the preparation was irrigated with a solution of about 10^{-4} *M* adenosine triphosphate in the same potassium chloride solution.

Glycerol-extracted muscle offers great advantages for electron microscopy[2] because it can be separated into extremely small fibre bundles for fixation. Fresh muscles were also used. In both cases fixation was for 30 min. or 1 hr. in a 1 per cent osmium tetroxide solution containing 0·12 *M* sodium chloride and veronal–acetate buffer[3] at *p*H 7·4. The material was washed for 30 min. in 0·1 *M* potassium chloride at *p*H 7·0, and then dehydrated in a series of ethanol solutions (50, 70, 90, 95 per cent: 2 hr. in each) and stained for 12–18 hr. in 1 per cent phosphotungstic acid dissolved in ethanol. Methacrylate or 'Araldite'[4] was used for imbedding. Thin sections were cut on a microtome designed by Dr. H. E. Huxley (prototype described in ref. 5), mounted on carbon films and examined in a Siemens 'Elmiskop I'.

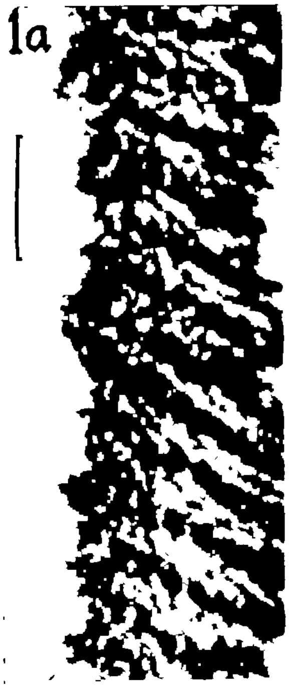
The Diversity of Smooth Muscles

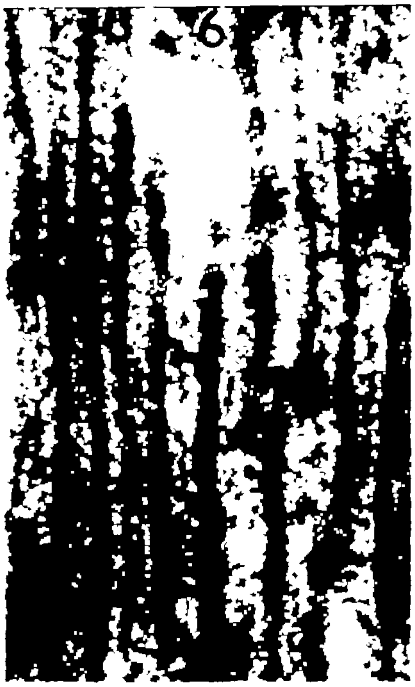
Smooth muscles from a variety of molluscs and also from annelids, *Phascolosoma* and vertebrates have been examined. The only feature they have in common to distinguish them from cross-striated muscles is that the filaments are not aligned into *A* and *I* bands. Some of the more interesting results of this survey will now be summarized. (The work on the white adductors of lamellibranch molluscs was done with Mr. G. F. Elliott.)

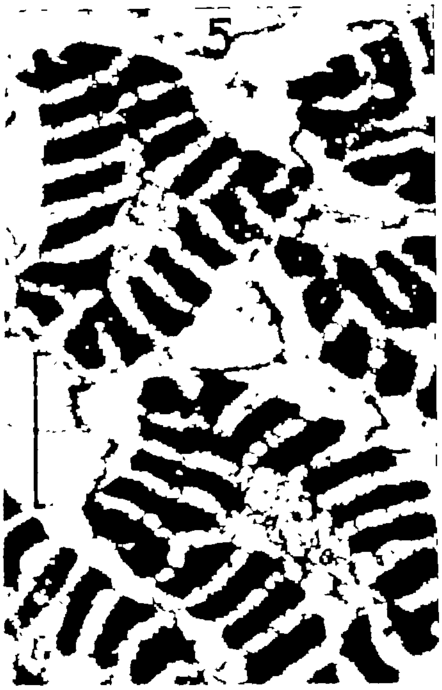
The myofilaments vary greatly in size and arrangement, and they may or may not be grouped together into fibrils. In the bladder muscles of the frog all the filaments are very thin—about 50 A. in diameter; no regularity can be discerned in the way in which they are packed side by side; and although the interior of the muscle fibre is not completely uniform in appearance, it is not possible to point to any differentiated groups of filaments (fibrils) separated from each other by regions free of filaments (sarcoplasm). Other vertebrate smooth muscles appear to be similar[9,14,15].

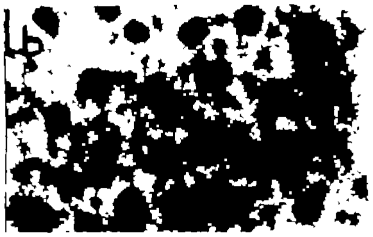
In striking contrast to these vertebrate muscles, the smooth muscle fibres of cephalopods (which have about the same diameter) contain distinct myofibrils, separated from each other by sarcoplasm with a highly organized 'reticulum'[10] system. Moreover, the fibrils consist of closely packed arrays of large filaments (diameter about 120 A.) between which lie small filaments (diameter about 50 A.) cross-linked to the large ones. A similar double array of filaments exists in cross-striated muscles[6,7] and in the smooth muscle fibres of the pharynx retractor of the snail, *Helix pomatia*[8]. But the snail muscle differs from the cephalopod muscle in several respects. The big filaments are larger and more variable in size (average diameter 250 A.); their arrangement is rather irregular, and they are not organized into fibrils.

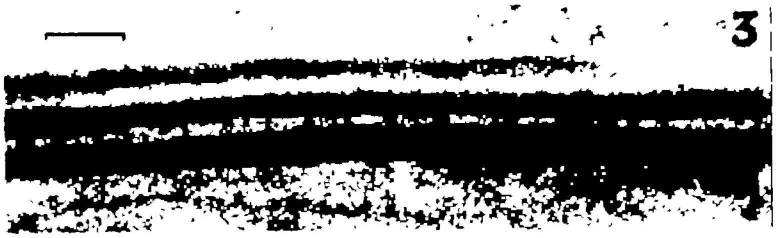
Yet another kind of smooth muscle fibre is found in the white (slow) part of lamellibranch adductors. It is already known[9] that here the 'filaments' are very large and highly variable in size (500–1500 A. in diameter) and randomly arranged in the lateral direction. We now find that these 'filaments' contain ribbon-shaped 'sub-filaments' which appear to be the paramyosin elements first isolated from blended muscles by Hall, Jakus and Schmitt[11]. We have been unable to identify any other filaments cross-linked to these very large and complex paramyosin-containing 'filaments'—perhaps the latter function as myofibrils.

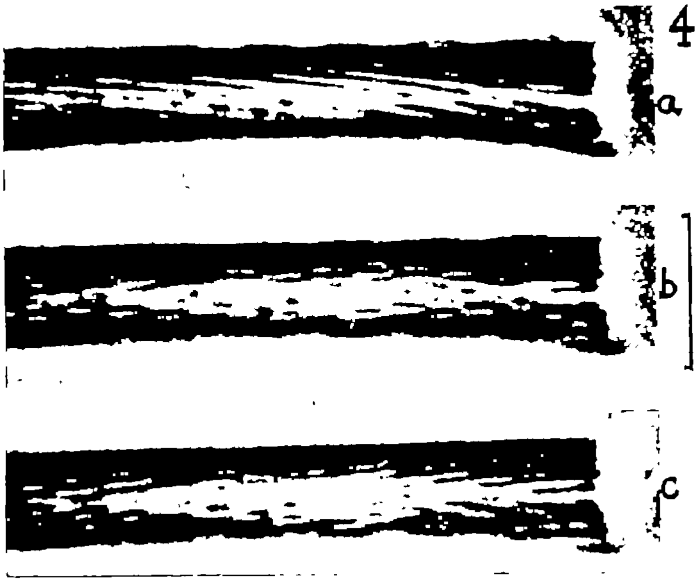


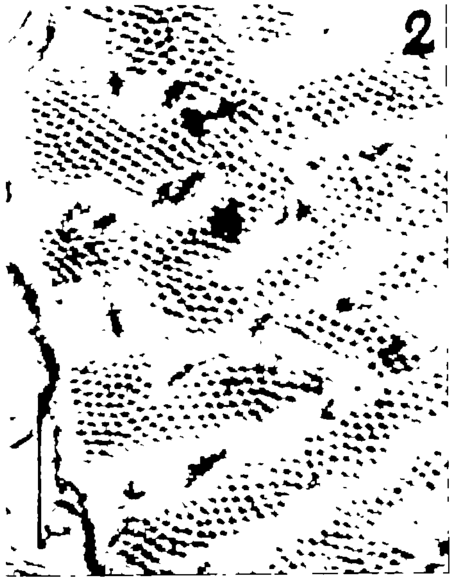












All the electron micrographs (Figs. 1, 2, 3, 5 and 6) are of material extracted with glycerol, fixed in osmium tetroxide and stained with phosphotungstic acid

Fig. 1, *a* and *b*. Transverse sections through fibrils in squid muscle Magnification mark, 0·1 μ

Fig. 5. Transverse section through squid fibres. Magnification mark, 1 μ

Fig. 6. Longitudinal section through a squid fibril. Magnification mark, 0·1 μ

It is known that paramyosin structure is not confined to slow lamellibranch adductors[10–13], but it may be even more widespread than has hitherto been realized. We have found an axial period like that of paramyosin in sectioned body-wall muscles of the earthworm (Fig. 3). This is of particular interest because these muscles resemble those of cephalopods in having well-differentiated myofibrils[9] which are helically arranged. The tinted (fast) parts of some lamellibranch-adductor muscles, for example in the oyster (Fig. 2), also have helical myofibrils, and here the presence of paramyosin has been shown by X-ray diffraction[14,15].

Helical Configuration of Moyfibrils

In the funnel retractor and mantle muscles of the squid, the myofibrils are helical. This can clearly be seen in the intact isolated fibre viewed at different focal levels in the phase-contrast microscope (Fig. 4). There is a single layer of fibrils lying in the periphery of the fibre. When the whole of the helix is in focus, the fibre shows the appearance known as 'double oblique striation'; but this is a misleading term, because the muscle is smooth. The helix is left-handed, and the angle it makes to the fibre axis depends on the degree of extension or contraction of the muscle. In mantle muscles tied at rest-length and fixed in formaldehyde, the angle was found to be small (6–12°); in other fibres allowed to shorten during fixation, the angles were greater (14–18°). Change of angle during contraction has been observed under the microscope in material extracted with glycerol and treated with adenosine triphosphate; in this case the angle can increase to as much as 60°.

The fibre is 5–10μ in diameter and has a core which is mostly occupied by a row of large mitochondria; the single nucleus lies among them. Around the core are arranged the myofibrils, which are ribbon-shaped and lie radially. The fibre is usually somewhat triangular in cross-section, and neighbouring fibres are closely packed together (Fig. 5).

The filaments composing the fibril always appear to follow the same direction as the fibril; unless they are rather short, they must be helical.

The appearance of 'double oblique striation' in the muscle fibres of many different invertebrate animals has been known for a long time. It has been variously interpreted, and in the most recent literature[17,18] on molluscan muscles it is regarded as an artefact produced by distortion in cross-striated muscles. Probably one reason for this mistaken interpretation is the fact that contractule elements are difficult to study in stained sections; moreover, alcohol fixation[16] shrinks the fibres and makes them so granular that the fibrils are obscured. Ballowitz[19] and Marceau[20] had previously published detailed accounts of the structure of cephalopod muscles, and they realized clearly that the fibrils are helical.

A helical configuration of myofibrils has been observed not only in cephalopod muscles, but also in the yellow part of the oyster adductor and in the adductors of *Ensis ensis*; in all these cases the angle made between the helix and the fibre axis increases as the fibre contracts, as can be seen when material extracted with glycerol is treated with adenosine triphosphate under the microscope.

Annelids also have helical myofibrils in their body-wall muscles[9]. In *Lumbricus*, *Nepthys* and *Myxicola*, it has been found that the helix is right-handed, whereas in the squid it is left-handed.

Dr. H. E. Huxley has pointed out to us that a muscle fibre with helically arranged contractile elements could develop tension and shorten if the core around which the helix is wound remains at constant volume and if the fibre cannot twist. This is a useful working hypothesis, because it may be assumed that the volume of the fibre remains more or less constant during contraction, and histological examination indicates that the fibres in the muscle are effectively anchored by connective tissue.

In many lamellibranchs (for example, *Cardium*) the yellow part of the adductor shows no signs of helical elements when it is at physiological lengths, but looks like a classical smooth muscle with numerous 'fibrils' parallel to the long axis of the fibre. When, however, it is allowed to shorten below physiological length—by breaking the hinge ligament, for example—then some very interesting patterns of dense bands appear in the fibres. These bands are obliquely or even helically arranged. Marceau[21] may in some cases have confused such appearances with helical myofibrils. Their configuration underlines the tendency for structures in molluscan muscles to be arranged helically. A similar tendency is seen in the cross-striated part of the scallop adductor.

Thus, at least three types of smooth muscles can be distinguished in molluscs by major structural differences discernible in the light-microscope. Some of these differences are only revealed when the muscles are allowed to shorten excessively, and they can be studied not only in fixed material but also during contraction induced by adenosine triphosphate in glycerol-extracted fibres under the microscope. The three types are: (i) smooth muscles of classical appearance which persists at all muscle lengths; for example, the slow, white parts of lamellibranch adductors; (ii) smooth muscles which have the classical appearance at physiological lengths, but develop oblique or helical dense bands on excessive shortening; examples are the fast, yellow parts of some lamellibranch adductors; (iii) smooth muscles with helical myofibrils which may or may not develop dense bands when they shorten; in the squid they do not, but in the yellow part of the oyster adductor, they do.

Double Array of Filaments

In two types of smooth muscles there is already good evidence[22] that the contractile apparatus is constructed in essentially the same manner as in cross-striated muscles[2]: it consists of two types of filaments cross-linked together.

In transverse section, a fibril in the funnel retractor or mantle of the squid shows a double array of filaments (Fig. 1). The larger filaments are angular, 100–140 A. thick, and lie about 350 A. apart in a hexagonal array. Enclosed within this array are smaller filaments, about 50 A. in diameter; their arrangement appears to be rather irregular, and there are frequently more than six around each thick filament. The bridges linking these two kinds of filaments are clearly seen in longitudinal sections (Fig. 6), where they are spaced about 150 A. apart in the axial direction, and arranged in the same manner as in rabbit psoas muscle.

In the pharynx retractor muscles of *Helix pomatia*, both the large and the small filaments are irregularly arranged, and there are many small filaments clustered around each large one and cross-linked to it; here the large filaments are thicker (usually 250 A.) than in the squid, but the small filaments are of about the same size. The axial arrangement of the bridges is the same as in the squid.

The whole length of one of these smooth muscle fibrils is therefore constructed in much the same manner as the *A* band of a cross-striated muscle[2,7]. It is not yet known, and it may be difficult to determine, whether the individual filaments in smooth muscles are continuous or discontinuous along the length of the fibril. It seems likely, however, that they are discontinuous. There are two reasons for this opinion. First, the existence of a double array of cross-linked filaments strongly suggests that these muscles contract by a 'sliding mechanism' like cross-striated muscles[23,24]. Secondly, the low-angle X-ray diffraction patterns of clam adductor muscles do not change when the length of muscle is altered[25]; in cross-striated muscles, a similar feature[26] is explicable on the hypothesis that the filaments slide past each other without changing their lengths[23,24].

Comparison between Smooth and Cross-striated Muscle

If the model we propose for these smooth muscles is correct, then certain features can easily be explained. The lack of cross-striation is clearly due to the absence of any transverse alignment of the filaments, as suggested earlier[22]; there are no regions consisting—like *I* bands—of thin filaments alone, and there are no regions where the thick filaments lie in transverse arrays, as in *A* bands. Moreover, the absence of *Z* and *M* lines should allow unlimited sliding of filaments relative to each other, so that such a muscle might be able to develop tension over a very wide range of lengths (as, indeed, it does in *Helix*[27] and *Holothuria*[28], for example) because cross-links could always be formed between the filaments, and, according to the theory[23] elaborated by A. F. Huxley[29] for cross-striated muscles, tension is determined by the number of cross-links.

Contraction bands in striated muscles develop when the *Z* lines meet the *A* band filaments[23]. Such bands would not be expected to occur in smooth muscles, and indeed we have not observed them within the physiological range of lengths. The nature of the dense bands described earlier in this article in certain excessively shortened molluscan muscles is now being investigated.

The fundamental similarity between cross-striated and smooth muscles is already becoming apparent from recent physiological investigations. Thus contraction is accompanied by similar optical[31] and thermal[32] changes; and force–velocity and length–tension relations are similar[27,30,34], as are the events accompanying stress relaxation[31]. Such differences as have been found are quantitative; smooth muscles are generally slower[33] and can maintain tension more economically[32]. Thus when measurements are made of the time to reach peak isometric twitch tension and of the half-decay time of this tension, it is found that in the smooth muscles from *Helix*, *Pinna*, *Mytilus* and *Pecten*, the ratio of these times of rise and fall ranges from 1 : 8 to 1 : 20, whereas in cross-striated muscles (and in squid mantle muscle) the ratio is no greater than 1 : 2 (Abbott, B. C., and Lowy, J., unpublished work). This finding cannot yet be explained in terms of structure; perhaps chemical factors are of even greater importance.

The significance of cross-striation remained unexplained. There is likely to be more than one reason for it. As regards the usual suggestion that cross-striation represents specialization for speed, it is well to remember that the gut muscles of arthropods are cross-striated. Similarly, the gut muscles in squid have the same helical arrangement of smooth myofibrils as is present in the mantle and retractor muscles, which are the fastest smooth muscles that have so far been studied.

We are much indebted to Dr. H. E. Huxley for help with electron microscope techniques, and for discussing this investigation with us at all stages. We are also grateful to Mr. H. R. Munden for technical assistance. We thank Prof. J. T. Randall and Dr. H. B. Fell for their encouragement of this work, and the director and staff of the Plymouth laboratory of the Marine Biological Association for supplying many of the animals and for laboratory facilities. One of us (J. L.) acknowledges the financial support of the Nuffield Foundation.

Electron Microscope Studies on Colloidal Silver Iodide employing Cinematographic Techniques

The examination of crystals of silver halides in the electron microscope is of considerable interest in view of their importance in photography. So far, most research has been carried out with crystals from photographic emulsions having sizes of the order of 5μ or greater. However, crystals of such magnitude suffer from the disadvantage that they are sufficiently thick to be opaque to an electron beam and usually decompose rapidly in the beam[1]; this is particularly so with silver bromide, which has been most investigated. This has led largely to the use of replica techniques for their examination[2]. Particles of colloidal dimensions seem to have received very little attention, possibly owing to the relatively low magnification and resolving powers of earlier electron microscopes.

Recently, in these laboratories, we have carried out extensive research on the formation and growth of colloidal particles using the Siemens Elmiskop I [3], which allows direct examination of specimens at instrumental magnifications of up to × 80,000 and × 160,000. The instrument was also modified for microdiffraction observations according to the method of Riecke[4]. Sols of silver iodide (negatively charged, stabilized by excess of iodide ions) may be produced having particles of various sizes[5] (10–5000 A.) and well-defined shapes and thicknesses according to the conditions of preparation; the thinner specimens to some extent transmit electrons. The predominant two-dimensional shapes are hexagonal and triangular; examination by microdiffraction shows them to be single crystals having a hexagonal structure.

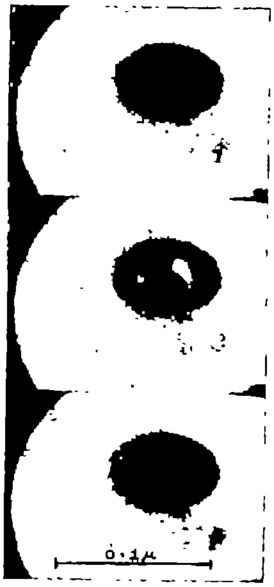

Fig 1 A sequence from a ciné film taken directly from the electron microscope screen showing a single crystal of silver iodide undergoing considerable contrast changes (× 200,000)

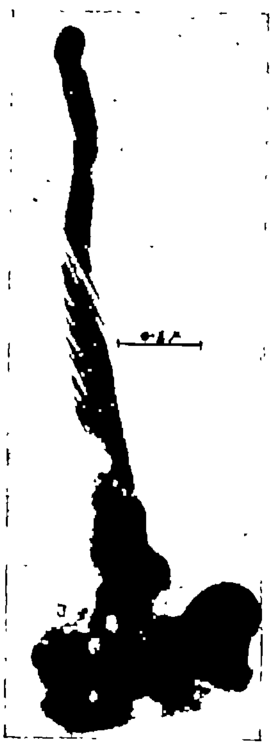

Fig. 2 Filament growth from a single tetrahedral particle of silver iodide after irradiation in the electron beam. (×100,000)

During our investigations, we discovered that silver iodide during electron irradiation shows several interesting features which appear to differ from those usually described in the literature for silver bromide; moreover, these features can be controlled. Two main types of behaviour are observed, namely, considerable changes of contrast which are mobile within the particle, and in some cases, notably with high beam intensities and certain crystal shapes, rapid filament-growth from the corners. Cinematographic recordings have been made of both these phenomena, and also of the microdiffraction patterns during these changes, by photographing directly the fluorescent screen of the electron microscope.

The nature of the contrast changes and the speed with which they occur is illustrated in Fig. 1, which shows a small single crystal of silver iodide (about 800 A. in diameter) that has undergone a considerable change in two consecutive frames of the ciné film (1/16 sec.). Regions formed during irradiation which are transparent to electrons move with great rapidity inside the crystal without effecting any change in external shape. By changing the illuminating intensity, the rate of movement can be controlled; by reducing it sufficiently, the effect can be stopped. The motion of the transparent areas continues indefinitely, without evidence of decomposition or the formation of small sputtered droplets around the particles (compare the behaviour of silver bromide[6]).

With certain types of particles a filament appears to be pushed outwards from the interior as the intensity of the electron beam is increased. It seems to form with the greatest frequency from the points of tetrahedral particles. Fig. 2 shows a filament formed from a tetrahedral particle. Closely spaced 'contrast bands' shown across the filament axis are frequently observed, and are often seen to move with great rapidity throughout the length of the extended region. Many of the filaments appear to be flat ribbons measuring as little as 30 A. across, yet remaining quite rigid. Preliminary micro-diffraction patterns of selected areas taken on single filaments indicate that they are silver iodide and not free silver.

The nature of the mechanism by which these effects occur has not yet been fully elucidated, and a full account of both the microscopy and diffraction of this system will be published elsewhere in due course. Such effects are, no doubt, closely associated with the mobility of the lattice units in silver iodide crystals and the charging effects and increase of temperature which occur in the electron beam. In the case of hexagonal silver iodide, a transition occurs at 145·8° to a cubic form[7]. However, so far no deviation in the micro-diffraction pattern from the hexagonal form has been observed; but an extension of the work to direct observations on specimens maintained at high temperatures in the electron microscope is in progress.

Finally, an important electron optical factor in these experiments is the use of a double-condenser lens illuminating system in the Siemens Elmiskop[3]. Illuminating probes of 5μ diameter were frequently used in the present work, and under these conditions the overall rise in temperature of the specimen is considerably reduced. It is difficult, therefore, to compare irradiation effects occurring during examination in the Siemens Elmiskop with work carried out on earlier electron microscopes fitted with a single condenser lens.

We wish to thank the Agricultural Research Council for financial aid to one of us (R. W. H.), Messrs. Ilford Ltd. for generous assistance with ciné film, and Mr. R. B. Collins, Dr. V. E. Cosslett and Dr. P. B. Hirsch, for valuable discussions.

Nature of the Lunar Surface

RECENTLY, Gold[1] has discussed the origin of the lunar craters and maria. He concurs in the meteorite impact theory of the origin of the craters advocated by Baldwin[2], and agrees in major conclusions on the impact of explosions with Gilvarry and Hill[3]. For strong reasons[4], Gold argues against lava as the agent producing the smooth dark surfaces of the maria (which he presumes to arise in the first instance merely as meteoritic craters considerably larger than the average). He proposes to explain the smooth surfaces by an erosion process creating dust in the highlands, coupled with a transport mechanism depositing it in the maria. The purpose of this communication is to point out the possibility of explaining simultaneously the erosion and transport required in Gold's theory, by a process known to be operative on the Earth on a large scale (in contrast to some suggestions by Gold and by Urey[4]).

It is a corollary to Gold's considerations that the Moon was formed cold; its strongly triaxial shape reflects the strength of the component materials, and it was never in hydrostatic equilibrium[1]. It follows that isostatic compensation is not, and never was, present. Terrestrially, a high level of earthquake activity of tectonic type is found where the isostatic gravity anomalies are large[5]. In spite of the approximate isostatic balance of the Earth, the total number of earthquakes is of possible order 10^6 annually; the corresponding release of energy[6] is about $1{\cdot}2 \times 10^{27}$ ergs. These considerations are consistent with a significant level of seismic activity of tectonic type on the Moon, sustained to the present throughout its history. It may be noted[5] that maximum gravity anomalies observed in the seismically active circum-Pacific belt are somewhat in excess of − 200 milligals. Assuming the maximum width and depth[2], a surface gravity anomaly can be computed of about − 450 milligals over the centre of the Alpine valley of the Moon, for no isostatic compensation[7]. Of the two figures, that for the Moon is greater in an absolute and relative sense, since the lunar gravitational acceleration is only one-sixth that of the Earth.

It will be postulated that seismic action represents a major erosive agent on the Moon, capable of reducing surface rock to rubble and (possibly with the co-operation of other agents) to fine particles and dust, in a time short compared to the lunar age. The seismic action will fill the bottoms of the craters with detritus eroded from the inner walls, as demanded in Gold's theory. To check sufficiency of such an erosive mechanism, it may be noted that the earthquake of 1897 in Assam caused complete destruction of buildings over an area[8] of 20,000 km.^{2}. For the same degree of destruction over the entire surface of the Moon, only 2,000 comparable shocks would be needed. Since the Moon's age is of order 10^9 years, these figures correspond to roughly one such extreme shock every million years (instead of the frequency observed on the Earth of possibly one every few centuries).

An effective transport process follows from the fact that the maria are on the average 2 km. lower than the lunar highlands[2]. The corresponding slope toward the maria is sustained only on the average, since it shows local elevations and depressions as does a mountain watershed. Intermittent moonquake activity permits the dust to escape over the rims of dust-filled depressions and to seek out the lowest gaps in obstructions, in order to slide and roll under gravity in the direction of the local slope. The seismic shaking prevents surface friction from arresting the flow, and no atmospheric resistance exists. The continual action of this process over the course of time will deposit dust from the lunar highlands in the lower maria, where its surface is maintained level by seismic agitation.

This hypothesis of seismic waves as the source of the agitation of the 'dust atmosphere' permits a considerably higher 'scale height' than does the thermal agitation suggested by Morrison[9]. Dust particles which have obtained a velocity from seismic acceleration can gain a vertical component of velocity by rebound from surface rock, to reach heights six times that possible on the Earth. A lunar seismic wave exhibiting the maximum amplitudes of ground acceleration (500 cm./sec.^{2}) and horizontal displacement (60 cm.) observed for an earthquake[10] could impart a horizontal velocity of approximately 200 cm./sec. to superficial dust. For perfectly elastic impact against massive rock, the maximum height of trajectory of a dust particle would be about 100 cm. These figures may correspond to an extreme assumption, but they imply that the levitation induced seismically may be sufficient for the dust to surmount minor asperities obstructing the flow. The transport mechanism suggested does not seem inadequate for the requirements of Gold's theory, in view of the low flow-rate necessary (to deposit dust to a depth of 1 mm. in 10^4 years)[1] and the large area which can be subjected to acceleration by an earthquake (about 5,000 km.^{2} for an acceleration greater than one-fifth that of terrestrial gravity, in the case of the earthquake of 1891 in Mino and Owari, Japan)[11].

I acknowledge valuable discussions with Prof. A. J. F. Siegert, of Northwestern University, and with Dr. R. B. Baldwin.

Internal Flaws in Bonded Cylinders of Soft Vulcanized Rubber subjected to Tensile Loads

It is not uncommon to subject rubber-to-metal bonded components to tensile loads lower than that required to break a well-bonded unit as a routine check of the bonding efficacy[1]. We have observed that internal fractures occur in soft vulcanized natural rubber cylinders bonded to metal end-pieces when subjected to comparatively low tensile loads. Such internal flaws may well pass undetected, but their presence might be expected to impair the strength, service behaviour and life. No previous account of their occurrence is known to us.

The rubber mixes used contained little or no carbon black, and gave vulcanizates having hardnesses in the range 30–45° British Standard. The test-pieces, in the form of cylinders 2 cm. in diameter and 0·07–0·50 cm. in height, were prepared by a moulding process and bonded by means of cements ('Ty Ply' *UP* and *RC*) to metal end-pieces during vulcanization. Load-deflexion relations in tension were determined using a Hounsfield tensometer, the deflexion being imposed at a speed of 0·16 cm./min.

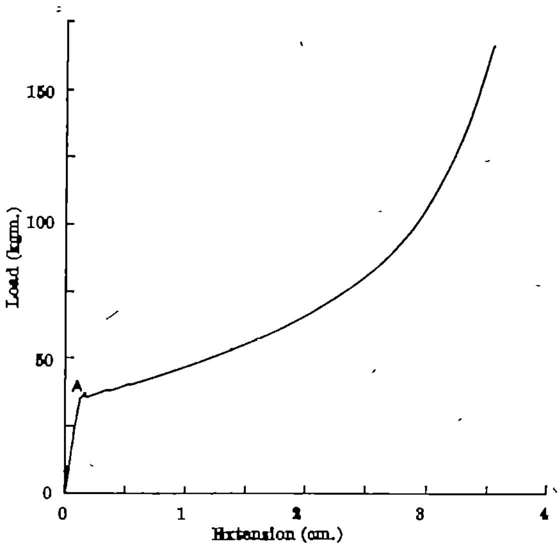

Fig. 1. Load-extension relation for a test-piece 2 cm. in diameter and 0·25 cm. thick, of hardness 45° British Standard

A typical load-deflexion relation is shown in Fig. 1. Similar relations were obtained for all the test pieces examined. Audible cracking was frequently evident from the point *A* onwards, and a cross-section of a test-piece cut open after a load of 57 kgm. had been applied is shown in Fig. 2. Several cracks about 0·3 cm. in length are visible in the central region. In thinner test-pieces a greater number of smaller cracks was found. The cracks often extended towards the bonded surfaces but did not appear to communicate with them, a thin film of rubber adjacent to the bond being unbroken.

It seems probable that the cracks are formed under the action of a negative 'hydrostatic' pressure, arising from the imposition of the present deformation on a substantially undilatable material, and analogous to the component of pressure proposed[2] to account for the load-deflexion behaviour of bonded units in compression. The magnitude of the negative pressure may be calculated in a similar manner; at the centre of a sufficiently thin test-piece it is found to be 2σ, where σ is the average tensile traction imposed on the bonded faces. From the load-deflexion relation shown in Fig. 1, therefore, cracking seems to have occurred when a negative pressure of 23 kgm./cm.^{2} was imposed. This value may be compared with the thresholds for cavitation reported[3] for water and for glycerine of 16 and 63 kgm./cm.^{2} respectively.

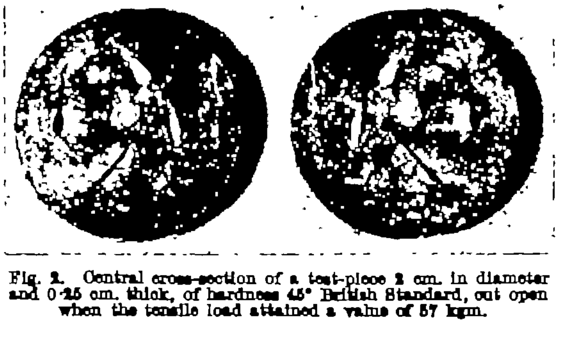

Fig. 2. Central cross-section of a test-piece 2 cm. in diameter and 0·25 cm. thick, of hardness 45° British Standard, cut open when the tensile load attained a value of 57 kgm.

It has been stated[4] that the presence of grit may lead to (unspecified) failures in the rubber when tests of rubber-to-metal bonded units are being carried out. It seems unlikely that grit was entirely responsible for the cracking reported above, since it was found in vulcanizates made from different batches of natural rubber, including one specially clean experimental sample.

This work forms part of a programme of research undertaken by the Board of the British Rubber Producers' Research Association, and will be reported in full elsewhere.

Preferential Ionization of Argon in the Presence of Air and its Application to Electric Discharge Devices

IN this Laboratory we have used the emission from electric discharges in gases, both for promoting fast reactions in photosensitive materials (for example, crystals of metallic azides), and for illuminating such events when recorded by the techniques of high-speed photography. For both requirements it is desirable not only that the discharge be of consistent and reproducibly high luminance and illuminating power, but also that it shall be reproducible in both space and time and in electrical properties. To these ends investigations are being undertaken here to determine the effects, *inter alia*, of variations of the principal parameters of the discharge gap, for example, length and diameter of discharge, type of gas, presence and type of discharge tube or surface, method of initiation, etc. Two types of discharge, (*a*) that of a duration of several milliseconds at approximately constant intensity, and (*b*) that of a duration of a microsecond or less possessing short rise and decay periods, are of particular interest.

It has already been shown[1,2] that the millisecond discharges of constant intensity may be started along any desired path by means of a vaporizing wire, and will continue for the duration of the applied energy pulse. It was therefore possible to match the potential drop (about 30 V./cm. in air or 15 V./cm. in argon) across a suitable discharge gap to the output voltage of the energy pulse from an electrical storage network. In a particular arrangement using a Guillemin network charged to 2,800 V., gaps of 14 in. in air and 19 in. in argon were crossed at pulse energies between 0·5 and 1·0 MW. Efficient energy conversion of about 25 lumens/W. was obtained. The system affords a convenient alternative to the silica envelope discharge tube where large dissipations of energy are involved, and would prove simple to extend to much higher powers, such as 5 MW., and longer durations, such as 100–1,000 msec.

An alternative method[3] has now been established for confining microsecond discharges to a desired, and repeatable, path. It was discovered that, in the presence of a stream of gas such as argon, flowing between the electrodes of a discharge gap, the discharge confined itself to a path within the argon. Spectrograms showed that the argon stream could be reduced to a cross-section having only 0·5 mm. diameter before there occurred any excitation of the surrounding gases (in this case air), when using a discharge energy of 2·5 J. It is convenient to construct the discharge gap (Fig. 1) with one electrode drilled axially, so that the argon may be introduced continuously and cross the gap axially. Provided that the axial hole and the electrode shapes are reasonably streamlined, a non-turbulent flow is readily established, while the low velocity of flow necessary involves a negligible consumption of argon. The ratio length/diameter of the gas stream, Fig. 2, may be as large as 60 : 1, though it is easier to achieve stable flow at lower ratios. In a particular case using a ratio of 18 : 1, a discharge was established across a gap of 9 mm. length. During the discharge, the luminous zone expanded to a diameter of approximately 2 mm., a volume change of 16 : 1. The wave-forms of the light emitted showed that emission rose to its peak value of 6×10^6 candles in 0·25 µsec.,

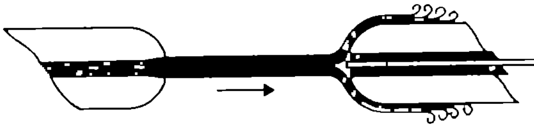

Fig. 1. An electric discharge gap blown with an axial, non-turbulent stream of argon injected through one electrode. The other electrode has been used to accommodate a trigger electrode

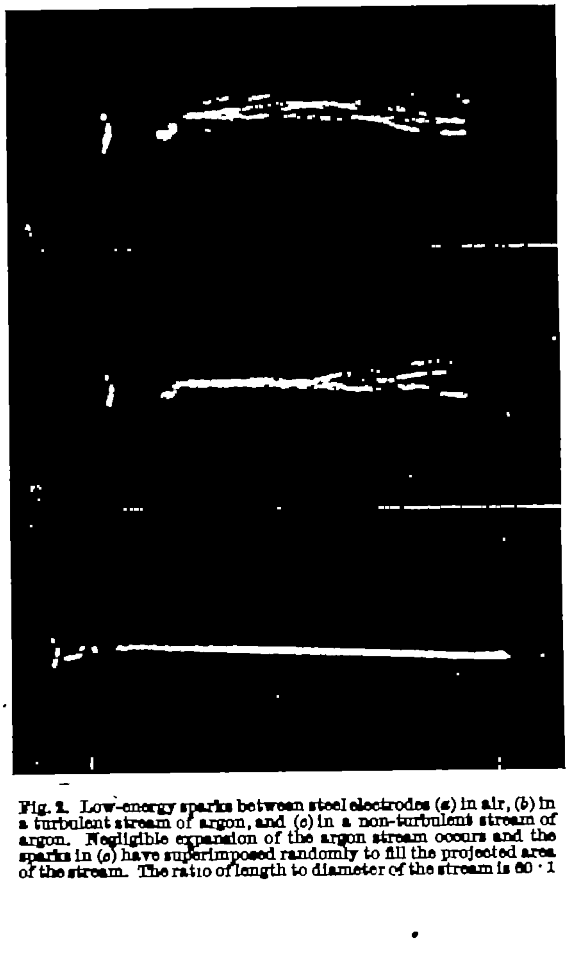

Fig. 2. Low-energy sparks between steel electrodes (*a*) in air, (*b*) in a turbulent stream of argon, and (*c*) in a non-turbulent stream of argon. Negligible expansion of the argon stream occurs and the sparks in (*c*) have superimposed randomly to fill the projected area of the stream. The ratio of length to diameter of the stream is 60 : 1

the duration at 50 per cent peak-level being about 0·5 μsec. This compares favourably with a similar discharge confined within a silica capillary tube, where the peak illuminating power was slightly less and the duration twice as long.

A considerable fraction of the emission appeared in the form of the argon 'blue' spectrum; so that, considered as a source, the electric discharge confined within an argon jet may have advantages beyond those associated with its stability of shape, size, position and emission. For example, in conjunction with a filter isolating the λ = 4345 A. region, it should prove an excellent source for high-speed interferometry.

No attempt has yet been made to establish the mechanism involved in the preferential ionization of argon in the presence of air. However, since the dielectric strengths of air alone and argon alone differ by a factor of about 2, the effect is perhaps not surprising.

Acknowledgment is made to Dr. J. S. Courtney-Pratt for his encouragement of the work and to Dr. F. P. Bowden for permission to publish this communication.

New Crystallite Orientations of Cellulose I in *Spirogyra* Cell-walls

During our work on barium sulphate in *Spirogyra*[1], clean cell-wall material was prepared, using methods applied earlier in isolations of cell-walls of fungi[2]. This induced us to pay some attention to certain problems concerning *Spirogyra* cell-walls. In the native state, these do not stain with chlor-zinc iodide, although Frey[3] definitely claims the presence of cellulose. Nicolai and Preston, discussing their X-ray examination of a great number of filamentous green algae[4], conclude that in very few families can it be claimed with certainty that the wall contains any cellulose common to higher plants, and that it is striking that such a well-known and often investigated genus as *Spirogyra* is still in doubt.

The main results of our X-ray and paper-chromatography investigations concerning these cell-walls may be briefly summarized as follows.

It was found that about 50 per cent of the cell-walls dissolves on successive treatments with hot 3 per cent potassium hydroxide and boiling 2 per cent hydrochloric acid. The acid dissolves about 23 per cent of the wall, and then contains galactose and xylose.

The residue yields an X-ray diagram which, so far as the spacings are concerned, corresponds to that of cellulose I and by its clarity suggests that the residue is comparatively pure cellulose.

In order to examine a possible orientation of the cellulose, cell-walls extracted as mentioned above were dried to flatness and heaped so as to form packets of nearly parallel walls. These were irradiated in directions parallel and perpendicular to the plane of the flattened cell-walls.

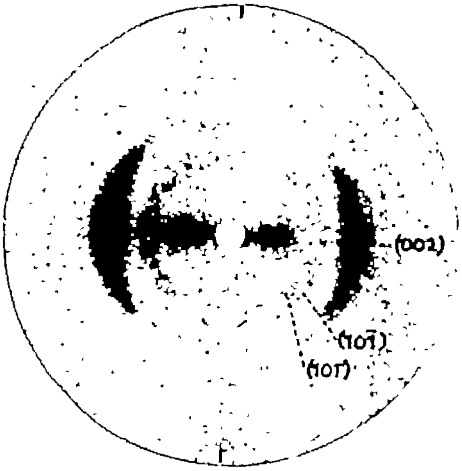

Fig. 1. X-ray diagram of packet of parallel *Spirogyra* cell-walls. X-ray beam in the plane of the walls; walls vertical and parallel to long edge of page. Note the diagonal position of the maxima of the $(10\bar{1})$ and (101) interferences

It could be concluded from the X-ray diagrams of these specimens and, as appeared later, also from similar specimens of native cell-walls, that the cellulose crystallites show a preferential orientation with a given crystal plane parallel to the wall. This has also been observed for other algae[5]. However, it is remarkable in my specimens that the oriented plane is not the one which is usually oriented parallel to the wall. So far, in both natural cellulose I membranes and membranes formed by drying down suspensions of particles of degraded cellulose I [6], (101) exclusively has been observed oriented parallel to the membrane. In my *Spirogyra* cellulose, I found the plane of orientation to be mainly (002), and also, in one species, it was observed that $(10\bar{1})$ is parallel to the wall. These orientations are shown in Figs. 1 and 2 respectively.

It has been reported that the crystallites of natural celluloses, or at least particles which probably represent the crystallites, are slightly flattened[6,7], (101) being the face of greatest extension. In my

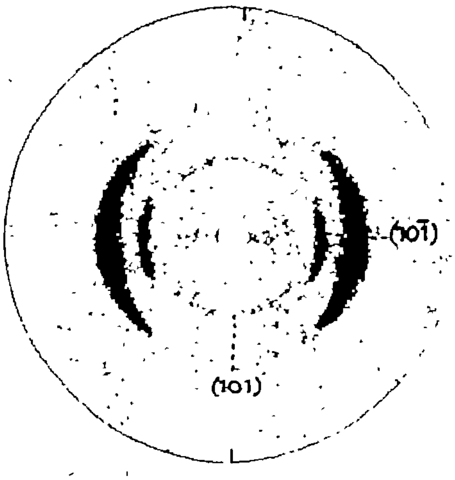

Fig. 2. Same as Fig. 1; but other species of *Spirogyra*. Note that the $(10\bar{1})$ interference arc has an equatorial position, whereas that of (101) is meridional

diagrams there is evidence suggesting that likewise in *Spirogyra* cellulose the crystallites are slightly flattened, with the face of greatest extension oriented in the plane of the cell-wall. This was supported by the low-angle scattering (not shown in Figs. 1 and 2). In other words, crystallites of natural cellulose I may also have, in addition to (101), either (002) or (10$\bar{1}$) as their face of greatest extension.

Frey-Wyssling[8] has directed attention to the fact that the OH groups on carbon atoms VI, VI′, XII and XII′ in the Meyer–Misch cellulose structure may freely rotate about the C—C bonds of these carbon atoms. He has pointed out that a given position of these OH groups, deviating from the position shown in the classical Meyer–Misch structure, could favour crystallite growth in (101). This could explain why thus far in natural celluloses (101) exclusively had been observed as the plane of lamination and growth in area of the crystallites, whereas on the basis of the Meyer–Misch model one would expect this plane to be (002).

In the light of Frey-Wyssling's considerations, our findings suggest that there might occur in Nature three structural modifications of cellulose I which differ by the position of the OH groups in question. These different OH positions might favour different directions of micelle growth.

Details of this work will be published elsewhere. It has been supported by the Netherlands Organization for Pure Research (Z.W.O.).

Degradation of Biologically Synthesized Lactose labelled with Carbon-14

AN investigation on the labelling of lactose-^{14}C from milk obtained from cows and goats was recently reported by Schambye[1]. The present communication describes a similar investigation on the distribution of carbon-14 in both hexose moieties of lactose obtained from the milk of a goat employing sodium formate-^{14}C as the lactose precursor (lactose-^{14}C was obtained through the courtesy of Mr. S. Misler, of these Laboratories).

A total of 123 mgm. of lactose-^{14}C were hydrolysed with 10 ml. of 0·5 *N* sulphuric acid in a sealed tube for 4 hr. at 100° C.[2]. The hydrolysate was adjusted to *p*H 4·5 with a saturated solution of barium hydroxide, filtered, the precipitate washed, and the filtrate plus washings concentrated to approximately 2 ml. using a current of warm air. The condensate was then chromatographed and scanned[3]. The scan showed the distribution of radioactivity between the two hexose moieties to be equal.

The galactose and glucose were separated and isolated using a coupled column of powdered cellulose (three sections, each diminishing in volume by one-half) and an eluting solvent consisting of ethyl acetate–pyridine–water (8 : 2 : 1)[4]. The total yield of the monoses was 46 per cent for glucose and 65 per cent for galactose.

The microbiological degradations of the hexoses were accomplished by a procedure similar to that of Bernstein *et al.*[5]. This degradation relies on the conversion of hexose to equimolar amounts of carbon dioxide, ethanol and acetic acid for each mole of hexose fermented as demonstrated by Gunsalus and Gibbs[6]. *Leuconostoc mesenteroides* cells required for Warburg fermentations were grown in the stock broth supplemented with separately sterilized 0·2 per cent glucose or galactose, depending upon the substrate to be degraded.

The fermentations employed for the initial step of the monosaccharide degradations were carried out at 30° C. under nitrogen in 125-ml. Warburg flasks containing 20 ml. of cell suspension in the main compartment with 0·03–0·05 m*M* substrate in the side-arm. At the conclusion of the fermentation, carbon dioxide was absorbed in alkali, removed, the cells inactivated by the addition of concentrated sulphuric acid and separated from the fermentation mixture by centrifugation.

Ethanol was isolated from the supernatant by distillation and then oxidized to acetic acid. Lactic acid was extracted from the distilland by ether extraction and treated with sulphuric acid and chromic oxide, yielding carbon dioxide and acetic acid. The step-wise degradation of acetic acid involved decarboxylation by the use of the Schmidt reaction as described by Phares[7] and the oxidation of the resulting amine to carbon dioxide.

Table 1. DISTRIBUTION OF CARBON-14 IN GLUCOSE AND GALACTOSE OF LACTOSE IN MILK

Carbon No.	1 × 10⁻⁶ µc./mgm. barium carbonate	Carbon No.	1 × 10⁻⁶ µc./mgm. barium carbonate
	Glucose		
1	3·3	2 + 3	1·8
2	1·5		
3	2·0	4 + 5 + 6	3·0
4	3·4	5 + 6	2·8
5	2·4		
6	2·9	1–6	2·9
	Galactose		
1	2·9	2 + 3	1·0
2	0·8		
3	1·1	4 + 5 + 6	3·0
4	3·7	5 + 6	2·3
5	2·3		
6	2·9	1–6	2·9

The degradation of both hexose moieties of the biologically synthesized lactose-^{14}C, summarized in Table 1, showed the degree of labelling in each of the carbons of the isolated hexose moieties to be, in decreasing radioactivity: carbon numbers 4, 1, 6, 5, 3, 2.

Kopsine and Strychnine: a Comparative Study of their Physiological Properties

KOPSINE, an indoline alkaloid, has been isolated from the leaves of *Kopsia albiflora*, L. and *Kopsia fructosa*, A.Dc. (Apocyanaceae)[1,2]. It is a monoacidic base, and its chemical structure has been found[3] to be as shown in Fig. 1.

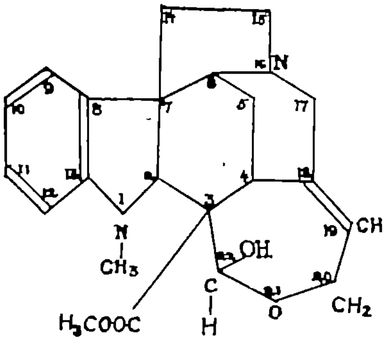

Fig. 1

Structurally, it has some similarity to some of the strychnos[4] and picralima[5,6] alkaloids. It has been suggested[3] that the structural configuration at carbon atom 3 (that is, the allocation of —COOCH$_3$ and cyclic acetal) fits into the modern conception of biogenesis of strychnos alkaloids[7].

The physiological properties of kopsine have been studied and the results have been compared to those of strychnine under identical conditions. The *p*H of the solutions of strychnine and kopsine was 6·5. A control study was made in each case by using Ringer's solution with *p*H adjusted to 6·5.

(1) Strychnine (1 mgm.) increases the excitability of the motor nerve cells. This action is very marked when strychnine is applied directly to the spinal cord. The same dose, or even higher doses, of kopsine show little effect. Preparations of spinal cord, nerve and muscles in toads were used for this work.

(2) Directly applied to the smooth muscles of the intestine or uterus of virgin rats and guinea pigs, 3 mgm. of strychnine has no effect. Kopsine in the same dose (3 mgm.) increases both the rate and amplitude of contraction of such muscles.

(3) Strychnine at a dose of 0·2–0·3 mgm. does not affect the cardiac contraction of toads. Kopsine at a dose of 0·2 mgm. reduces the cardiac contraction—both rate and amplitude. This effect becomes more pronounced as the dosage of kopsine is increased. With high dosage (0·5 mgm.), there is temporary cessation of the cardiac activity. For such investigations, toad heart perfusion experiments have been used.

(4) Neither strychnine nor kopsine influences the peripheral blood flow in toads as studied by the flow pressure perfusion technique at a dose of 100 mgm. per 100 ml. and by venous drop recording method using 5–15 mgm. of either.

(5) In urethane-anæsthetized cats, strychnine in the dose 2 mgm. per kgm. body-weight lowers the blood pressure slightly only (8–12 per cent) when the basal level of blood pressure is between 120 and 140 mm. mercury. Kopsine at a dose of 2 mgm. per kgm. body-weight reduces the blood pressure to a greater extent (15–35 per cent), under identical conditions. The hypotensive effect of kopsine (varying the dosage between 2–5 mgm. per kgm. body-weight) is much greater than that caused by strychnine of same dosage. When such a higher dosage of strychnine is used, respiration stops and there are marked convulsions and inhibition of cardiac contractions. But with higher dosage of kopsine convulsions never occurred in toads or cats.

Thus physiologically, kopsine possesses cholinergic effects, and its site of action is peripheral and not at the cerebrospinal axis as is that of strychnine. In the experimental preparations mentioned, it has also been found that kopsine and strychnine do not antagonize each other. Curiously enough, the hypotensive effect seen with kopsine has been observed in the deacetylated products of aspidospermine[8], which is of the same origin (family: Apocyanaceae) as is kopsine. Strychnos alkaloids are, however, of different origin (family: Loganiaceae).

Whether in the biogenesis of strychnos alkaloids the cholinergic action has been shifted from a peripheral effect (heart, smooth muscles, etc.) to a central effect (central nervous system) is now being investigated, as well as physiological properties of acetylated and deacetylated products of strychnine and allied substances.

We thank Dr. A. Chatterji and A. Bhattacherjya, Department of Pure Chemistry, University College of Science, University of Calcutta, for the supply of the chromatographically analysed drugs used for these experiments.

An Antibiotic from Maggots

IN 1929, Baer[1] introduced maggot therapy into clinical practice as an adjunct to surgery for the treatment of osteomyelitis. This technique became widely used in North America, and was extended to the treatment of other lesions where there was pyogenic infection or tissue necrosis[2]. Maggots were believed to have a threefold action within a wound: débridement of necrotic tissue by means of proteolytic enzymes[1], stimulation of granulation tissue due to the larval excretion allantoin[3] and reduction of wound infection. Baer[1] did not consider reduction of wound infection to be merely the result of débridement and tissue stimulation, and Robinson[3] has shown that allantoin, even in concentrations up to 8 per cent, has no antibacterial activity.

The work described in the present communication has been undertaken because it was considered that an anti-bacterial agent, having the properties of a true antibiotic, might be responsible for some of the beneficial effects of maggot therapy.

Young larvæ of the black blow-fly *Phormia terraenovae* were fed on raw beef, transferred to a suitable container and sprayed with distilled water at 10-min. intervals over a period of 3 hr. The washings were allowed to drain off, carrying with them a suspension of the maggot excretions. This aqueous suspension was sterilized by heating for 30 min. under 15 lb. pressure. When diluted with suitable fluid culture media, this material was found to be bactericidal against hæmolytic streptococcus group *A* at a concentration of 150 µgm./ml. (initial inoculum 10^4 log phase organisms/ml.). Against pneumococcus type I the potency was even more marked, a concentration of 30 µgm./ml. being bactericidal and half this amount was bacteriostatic. *Streptococcus haemolyticus* group *B* and *Streptococcus viridans* were shown to be sensitive at high dilutions. *Staphylococcus aureus* and *Clostridium welchii* were much less sensitive; *Bacillus coli, Proteus vulgaris, S. typhimurium, B. subtilis* and *Candida albicans* were all highly resistant. Bactericidal activity is optimum when the initial *p*H of the culture medium is between 7 and 8. In addition to this, the preparation is partially inactivated by washed agar, filtered serum and whole blood.

It has been found possible to isolate the antibiotic fraction in the washings by means of a chromatogram. 0·5 ml. of the maggot washings was deposited as a thin streak 15 cm. long on Whatman No. 1 chromatography paper. The solvent consisted of a 2 per cent solution of *p*-toluene sulphonic acid in *n*-butanol previously saturated with 2 per cent saline[4]. After drying in warm air, the chromatogram was cut into strips 2 cm. wide and 8 cm. long. These were then sterilized by ultra-violet light and embedded in agar. Antibiotic activity was detected by streaking lengthwise over the strips with *Staphylococcus aureus* (Oxford) and, following incubation, noting any areas of inhibition. Using this system, a zone of activity was located with an R_F value of 0·63 (Fig. 1). By means of a cellulose column and a modification of the chromatogram technique, it has been possible to obtain relatively pure samples of the antibiotic fraction in maggot washings. It has also been found that a series of injections of 25–50 mgm. of this preparation will protect mice from the lethal effects of intraperitoneal inoculation with Type 1 pneumococci (Fig. 2). By further purification it is hoped to improve the potency of the extract and to determine the basic chemistry of the active agent. At present the exact source of the antibiotic is not known, but it seems probable that it is a product of the larvæ themselves and not of micro-organisms associated with them.

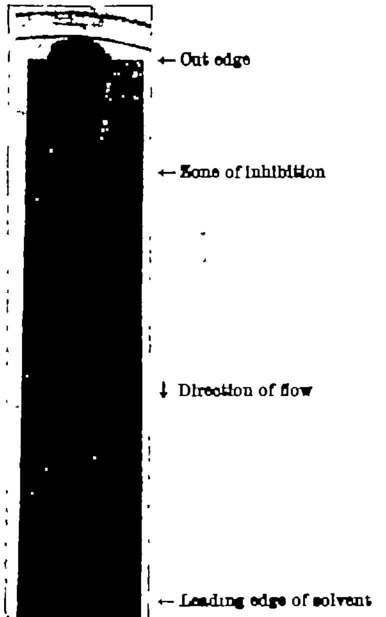

Fig. 1. Strip of chromatogram (dark rectangle) embedded in agar. The central band with a wavy margin is made up of colonies of *Staphylococcus aureus*. Note abrupt zone of inhibition at the upper end

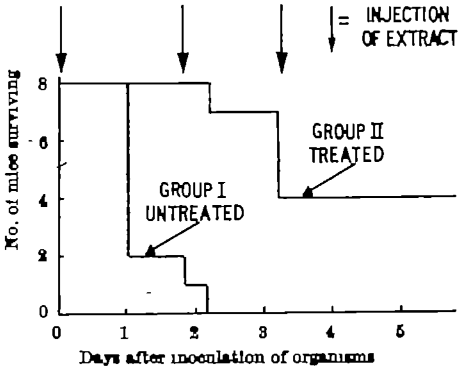

Fig. 2. Histogram showing survival times for two groups of *BALB/C* mice inoculated with 10^8 pneumococci intraperitoneally. Group II received 25–50 mgm. of larval antibiotic extract intraperitoneally at times indicated (survivors killed after 14 days)

It is hoped to publish full details of this work elsewhere.

We wish to thank Prof. R. Cruikshank, Dr. W. Howard Hughes and Dr. D. Hobson for helpful advice.

Serum Protein Differences in Cattle by Starch Gel Electrophoresis

Genetical differences obtained with cattle serum proteins by starch gel electrophoresis have been reported briefly[1]. This communication gives details of the distribution of the phenotypes, and some mating results.

The apparatus employed is similar to that of Smithies[2], except that platinum electrodes are used and all four vessels are filled with electrolyte (42 gm./l. disodium hydrogen phosphate adjusted to *p*H 7·8 with saturated potassium dihydrogen phosphate). Starch gels are prepared at 15 per cent w/v from acid-hydrolysed potato starch (Hopkins and Williams) and a 1-in-50 dilution of electrolyte. The serum samples are inserted into the gels on pieces of Whatman *E*17 filter paper, 1·3 cm. × 0·6 cm.; three serum samples can then be run side-by-side in one 4-cm. wide gel. The current density used is 5 m.amp./cm. width of gel for gels 25 cm. long (approximately 250 V. across the electrodes). The pieces of filter paper are removed after 1½ hr.; after 4 hr. the trailing edge of the albumin has usually migrated about 4 cm.

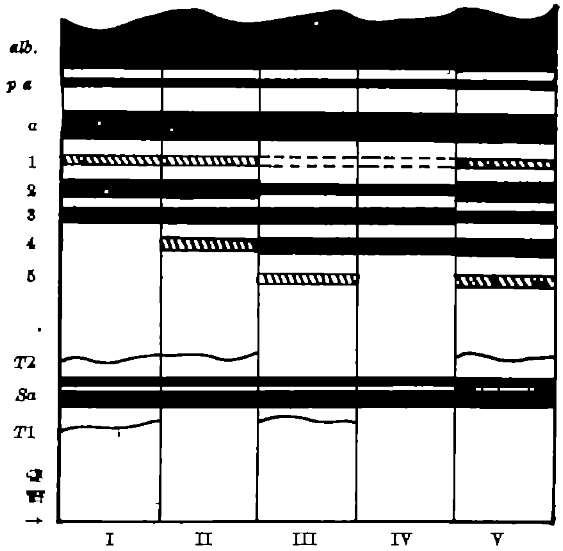

Fig 1 Diagrammatic representation of cattle serum protein patterns by one-dimensional starch gel electrophoresis. Note: The results shown were obtained from single offspring born to 150 selected cows mated to one of 33 bulls.

Examples of the patterns obtained are shown diagrammatically in Fig. 1. The nature of the components in one-dimensional starch gel electrophoresis has been determined by two-dimensional electrophoresis[8], first in agar and then in starch gel (Fig. 2). The β_2-globulin zone gives four, five or six components depending on the serum type, the various combinations of these components allowing recognition of five β_2-globulin phenotypes (I–V, Fig. 1). Table 1 shows the distribution of these five phenotypes among 352 bulls at the Milk Marketing Board Cattle Breeding Centres.

The β_2-globulin phenotype of an individual animal appears to remain constant, no change being observed in individual cattle on re-sampling over a period of twelve months. Prolonged storage of serum at − 15° C. has no effect on the β_2-globulin pattern obtained. Examination of forty-two pairs of monozygous twin sera showed that in each case both members of the pair gave the same β_2-globulin pattern, suggesting genetical control. Results from 150 matings are presented in Table 2.

It seems possible from the results available at present that this system is controlled by five pairs of linked genes, so that each of the individual β_2-globulins is seen in the presence of a single or double dose of one allele of the appropriate pair, but is absent in the presence of a double dose of the other allele.

The 'thread proteins' also seem to be under genetical control, resulting in four phenotypes (Fig. 1) independent of the β_2-globulin phenotypes. However, the results obtained with this system are not reproducible, and further work is required to elucidate the mechanism.

I thank Mr. G. F. Smith, chief veterinary officer of the Milk Marketing Board, for making available bull blood; also Drs. Hall and Jamieson, of the Animal Breeding Research Organization, Edinburgh, for supplying the monozygous twin sera, and Mr. A. L. Ogden, of this Station, for collecting blood samples in Norfolk and Suffolk.

Purification of β-Glucuronidase from Female Rat Preputial Gland

Because of the enormously high activity of β-glucuronidase in the preputial gland of the female rat[1], this tissue appeared to be a promising source of the purified enzyme. For other tissues employed for this purpose, the specific activity, the degree of purification and the recovery are as follows: ox liver[2] (32,000, 800-fold, 5 per cent), calf spleen[3] (7,900, 1,400-fold, 1 per cent), calf liver[4] (60,000, 9,000-fold, 10 per cent). The specific activity is expressed as μgm. phenolphthalein liberated from phenolphthalein glucuronide by 1 mgm. of protein in 1 hr. at 37° C., and the last two preparations were assayed in presence of deoxyribonucleic acid. A specific activity of 107,000 was observed with the best individual preparation from calf liver[4], and this was claimed to represent a purity of 85 per cent.

Crude preparations of the preputial gland of the female rat have specific β-glucuronidase activities similar to that quoted for the purified enzyme of calf spleen, and much higher specific activities than any yet reported can easily be obtained after four consecutive stages of fractional precipitation. In the experiment summarized in Table 1, twenty-one rats, 4–6 months old, yielded 2·2 gm. preputial gland which was homogenized in water. The homogenate was made 0·1 *M* with respect to acetate buffer, *p*H 5·2, in a final volume of 22 ml. After 2 hr. at 37° C., insoluble material was removed by centrifuging, and the supernatant was fractionated as shown. Precipitation, followed by sedimentation (10 min. at 20,000*g*) after 30 min., and dialysis of the fractions were done at 0° C., but other manipulations were at ordinary room temperature. Solutions were buffered to *p*H 5·2 with 0·1 *M* or 0·01 *M* acetate buffer, and dialysed against the more dilute buffer. Losses in enzyme activity were in part due to the discard of less-pure fractions: there appeared, for example, to be no enzyme inactivation during the final fractionation.

Table 1. One Glucuronidase Unit (G.U.) liberates 1 μgm. Phenolphthalein from 0·00063 *M*-Phenolphthalein β-Glucuronide in 1 hr. at 37° C. and *p*H 5·2 (0·05 *M* Acetate Buffer). Percentages of Saturated Ammonium Sulphate Solution and Ethanol are by Volume. Protein was determined by the Method of Lowry *et al.*[6], employing Bovine Albumin as Standard

Fraction	G.U./mgm. protein	Recovery, G.U./gm. moist tissue

Supernatant	11,200	979,000
20–30 per cent sat. ammon. sulphate sol.	17,700	845,000
20–45 per cent ethanol	31,000	564,000
33–60 per cent sat. ammon. sulphate sol.	71,200	205,000
45–50 per cent ethanol	107,000 193,000*	188,000 228,000*

* Enzyme assay in presence of 0·03 per cent deoxyribonucleic acid.

In agreement with Fishman and his co-workers[3], the enzyme, especially in an advanced state of purity, displayed a reduction in net activity on dilution, and this was reversed by a variety of substances, such as deoxyribonucleic acid, albumin or enzyme inactivated by heat. It should, however, be noted that the figures in Table 1 are not strictly comparable with the measurements of specific enzyme activity quoted by these authors[3,4], since we employed albumin as our reference protein while they used the more chromogenic protein, chymotrypsin[5]. To correct for this, our own results should probably be multiplied by 1·5 throughout.

Since the β-glucuronidase activity of preputial gland of the female rat is under ovarian control[1], this tissue would appear to be ideal for studying the biosynthesis of the active protein.

Excretion of Yttrium and Lanthanum Chelates of Cyclohexane 1,2-*Trans* Diamine Tetraacetic Acid and Diethylenetriamine Pentaacetic Acid in Man

The removal of stable or radioactive toxic elements from the human body is of considerable interest[1]. The modification of tissue distribution and excretion of metal ions by chelating agents has been studied in man and animals in several laboratories[2]. Although ethylenediamine tetraacetic acid has been the most effective chelating agent thus far studied, it has the disadvantage that relatively large doses are required in order to effect a significant removal of heavy metal ions, particularly radioactive rare earths. Therefore metal chelates having stability constants higher than the corresponding metal chelates of ethylenediamine tetraacetic acid were investigated for their effectiveness in removal of rare earth elements.

This communication reports observations on the urinary excretion of intravenously administered yttrium and lanthanum chelated with *cyclo*hexane 1,2-*trans* diamine tetraacetic acid[3] (CDTA) and with diethylenetriamine pentaacetic acid[4] (DTPA). The excretion of these metal chelates has been compared with the excretion of the yttrium and lanthanum ethylenediamine tetraacetic acid chelates.

Yttrium and lanthanum chelates of ethylenediamine tetraacetic acid, *cyclo*hexane 1,2-diamine tetraacetic acid and diethylenetriamine pentaacetic acid, using 1·2 : 1 chelate to metal molar ratios, were administered intravenously to man. Yttrium and lanthanum were administered in 1·0-mgm. and 1·5-mgm. quantities labelled with yttrium-90 and lanthanum-140 respectively; they were determined in plasma samples and in aliquots of urine and the

Y-DTPA	5·0	75·0	1·8	93·0	0‡	101·3
La-EDTA	40·5	1·4	23·1	1·6	8·1	2·1
La-CDTA	25·5	8·2	17·7	8·6	6·0	12·1
La-DTPA	8·4	50·8	3·4	58·0	1·0	60·5

* Percentage of the administered dose in total plasma volume.
† Percentage of the administered dose.
‡ Background.

values expressed as percentages of the injected dose. On the basis of previous studies of yttrium and lanthanum excretion[2], it was assumed that the metals were excreted by the kidney mainly as the metal chelate. A representative example of a comparative study carried out with the yttrium and lanthanum chelates in one patient is shown in Table 1.

Table 2 lists the twenty-four hour cumulative urinary excretion in a group of patients receiving the yttrium and lanthanum chelates. These results show quite conclusively that even at tracer-levels yttrium *cyclo*hexane 1,2-*trans* diamine tetraacetic acid and yttrium diethylenetriamine pentaacetic acid are excreted within eight hours in amounts approaching 100 per cent of the administered dose, whereas yttrium ethylenediamine tetraacetic acid is eliminated somewhat in excess of 50 per cent of the injected dose. The first is excreted in slightly smaller amounts than the second. The superiority of diethylenetriamine pentaacetic acid over *cyclo*hexane 1,2-*trans* diamine tetraacetic acid in effecting lanthanum excretion is indicated by the results in Tables 1 and 2.

The complete urinary excretion of the yttrium diethylenetriamine pentaacetic acid chelate suggests the use of the radioactive metal chelate as a vehicle for introducing ionizing radiation into the body. This type of treatment would permit a controlled exposure to total-body radiation over a period of several hours to days as compared to a relatively brief exposure to the same amount of radiation by X-rays. The quantity of radiation and the time of exposure could be controlled by the radioactivity of the isotope, the speed of infusion and the molar ratio of the metal to the chelate.

Results correlating the urinary excretion of chelated yttrium with the stability constant of the metal chelate have been reported in a previous communication from this laboratory[5]. These indicated that the higher the stability constant of the metal chelate, the larger the excretion. The stability constants of the lanthanum and yttrium *cyclo*hexane 1,2-*trans* diamine tetraacetate acid chelates have been found to be greater than the corresponding metal chelates of ethylenediamine tetraacetic acid[3]. Although no published data are available on the stability constants of the yttrium and lanthanum chelates of diethylenetriamine pentaacetic acid, unpublished results indicate that the latter binds polyvalent metal ions at least as strongly as *cyclo*hexane 1,2-*trans* diamine tetraacetic acid[6].

Table 2. URINARY EXCRETION OF YTTRIUM AND LANTHANUM CHELATES IN 24 HR.
(1 mgm. yttrium or 1·5 mgm. lanthanum ion and 5 mgm. chelating agent were injected intravenously; yttrium-90 and lanthanum-140 were used as tracers)

Metal chelate	No. of patients	Urinary excretion as percentage of administered dose Range	 Average
Y-EDTA	11	38·3–87·6	55·9
Y-CDTA	13	75·3–97·6	87·9
Y-DTPA	6	81·6–102·4	96·7
La-EDTA	3	2·1–3·1	2·6
La-CDTA	3	9·4–12·2	11·2
La-DTPA	4	60·4–71·8	64·6

The effectiveness of a chelating agent as a detoxicant for heavy metals can be predicted from the urinary excretion of the intravenously injected metal chelate. Therefore, both *cyclo*hexane 1,2-*trans* diamine tetraacetic acid and diethylenetriamine pentaacetic acid, especially the latter, should be more effective than ethylenediamine tetraacetic acid in removing yttrium and lanthanum from body tissues and fluids. These results further support the conclusion that the stability constant of a heavy-metal chelate represents a reliable basis for predicting the effectiveness of a chelating agent in detoxifying a physiological system contaminated with heavy metal ions.

This study was conducted under contract *AT*(30-1)-1551 with the U.S. Atomic Energy Commission.

We thank the Geigy Chemical Corporation, Ardsley, New York, for a generous supply of *cyclo*hexane 1,2-*trans* diamine tetraacetic acid and diethylenetriamine pentaacetic acid.

Site of Chloride Regulation in Marine Fish Larvae

DURING current investigations into the laboratory conditions necessary for consistently successful marine fish-rearing, it has become increasingly evident that the osmotic hazard confronting the early larva is much greater than that facing the adult. Both larva and adult live under an osmotic strain, having internal salt concentrations roughly one-third that of the surrounding sea water.

The integument of the plaice larva is a thin syncytial membrane[1], partially separated from the muscular axial tissue by a voluminous sub-dermal space[2]. Its ability to do osmotic work can be critically affected by external changes in the physico-chemical environment, and by the internal energy supply. Unfed larvæ quickly succumb to the osmotic strain, after complete loss of yolk. The thick, secretory, scaly skin of the adult, on the other hand, is virtually water- and salt-proof, osmotic leakage being restricted to the gill surface and oral membranes. Temporary starvation is never critical; food reserves provide energy for osmotic needs over long periods.

In both young and old, regulatory mechanisms are necessary to offset water loss and salt gain under the osmotic gradient. The adult swallows sea water to make good loss of water. The larger and less mobile ions, for example, magnesium, calcium and sulphate, are eliminated with the fæces[3]; water and the remaining electrolytes pass through the gut wall into the blood stream. Excess chloride is secreted to the outside by special cells in the gills[4]. The essential structural requirements for this mechanism of salt control are not generally present in emergent marine fish larvæ. The blood circulation is not yet complete and the gill filaments are absent. Where then, and how, do marine larvæ regulate their internal chloride concentration?

Copeland[5] used a modification of the Leschke chloride test for investigating the chloride secretory cells of the adult *Fundulus heteroclitus*. My larval technique is broadly based on that of Copeland. Living yolk-sac larvæ of plaice, cod and dab were washed in distilled water for 3 sec., then plunged into a dilute acid–silver nitrate solution in a dark room, under a safe light. After 3 hr. impregnation, the larvæ were washed thoroughly in distilled water to remove all traces of silver nitrate; immersed in dilute photographic developer solution for 1 hr.; rinsed; fixed in 'hypo' for ½ hr.; washed, dehydrated, cleared and mounted. Light precautions must be very strict until the 'hypo' stage.

A remarkable and consistent feature of treated larvæ is the fine, heavily stained, continuous network ramifying over the whole integument. This reticulum (Fig. 1) bears globular, corpusculate, nucleated bodies on its meshes, aggregations of which form characteristically heavy deposits around the yolk sac and in the fin fold. Smaller stained particles lie between the meshes, which at first sight appear to outline the boundaries of epithelial cells in the integument. The transverse section shown in Fig. 2 does not support the cellular theory. The network clearly has different properties from the rest of the unstained integument and lightly stained main axial tissues. If this conspicuous and regular pattern truly represents distribution of chloride in the larval plaice, then the whole thin integument, particularly around the yolk sac, is intimately concerned in regulation. The integument of a living larva, in bad conditions under the microscope, is noticeably active. The globular bodies become very prominent, and can frequently be seen to discharge their mucoid contents to the outside. Cellular discharge is always accompanied by local loss of integumental surface area, and is probably responsible for the normal diminution of the outer yolk sac during yolk utilization.

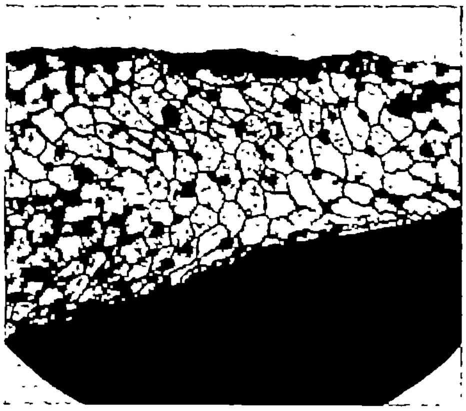

Fig. 1. Silver-stained network in dorsal marginal fin; high power. Photograph by R. Elms

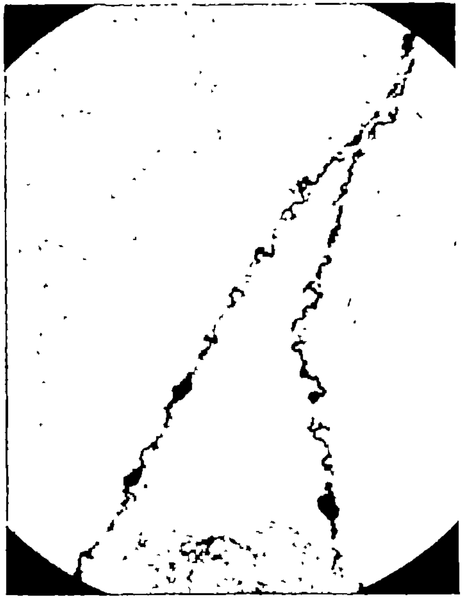

Fig. 2. Transverse section through dorsal marginal fin and larval trunk; high-power. Photograph by R. Elms

The specificity of acid–silver nitrate as a histochemical reagent has rightly been criticized by Lison[6] and many others. As well as reacting with tissue chlorides to produce silver chloride, unstable in the light, silver nitrate can be reduced directly to silver by vitamin C. Artefacts are often produced by silver salt fixatives, although rapid larval fixation in Baker's calcium-formaldehyde just before silver impregnation served to emphasize still further the regularity of the larval network. Copeland's technique assumes the initial formation of insoluble silver chloride in the tissues, made visible by controlled reduction in developer solution. I have obtained some evidence to support this assumption by using known solvents of silver chloride.

If silver-fixed larvæ are treated with 0·1 N solutions of ammonia, sodium thiosulphate or sodium cyanide after impregnation, negative results are always obtained on subsequent development, although the unstained globular bodies still remain visible in the integument.

Larvæ fixed in 5 per cent chloride-free formalin for 2 min., followed by normal treatment, gave positive results. Formalin-fixed larvæ allowed to remain in formalin, or distilled water, for ½ hr. gave negative results, suggesting that the cellular reactant is only loosely bound in the integumental network, and quickly diffuses out after death in chloride-free preservative.

An attempt is being made to test this histochemical evidence using one of the two available radioisotopes of chlorine.

Effect of Flavin Monosulphate on Old Yellow Enzyme

When flavin mononucleotide combines with the protein of old yellow enzyme to form the holoenzyme, the fluorescence of the free mononucleotide disappears[1]. This quenching of fluorescence has been attributed to bond formation between the protein and the imino NH(3) group of the flavin mononucleotide[2], and Weber[3] has suggested that the tyrosyl hydroxyl group of the protein may be responsible. In support of this hypothesis, Nygaard and Theorell[4] showed that 3,5 iodination of some of the tyrosyl groups resulted in a drastic change in the association and dissociation velocity constants. In addition to the binding of the imino NH(3) position, the extensive kinetic studies of Theorell and Nygaard[4–7] on the combination of old yellow enzyme apoprotein with its prosthetic group have indicated that the phosphoric acid residue of flavin mononucleotide is attached to (probably two) primary amino-groups in the protein.

Flavin monosulphate, the sulphate analogue of flavin mononucleotide, has been synthesized by Takahashi, Yagi and Egami[8] and shown to be a competitive inhibitor of the association reaction of the protein of D-amino-acid oxidase with its prosthetic group, flavin adenine dinucleotide[9]. The quenching of flavin derivatives by phenol has been studied by Yagi *et al.*[10,11], and it is believed that this quenching results from complex formation between the phenolic hydroxy group and the imino NH(3) group of the isoalloxazine nucleus. Since the fluorescence of flavin monosulphate, which is equal to that of the mononucleotide, is quenched by phenol, it was of interest to determine whether it would combine with the apoprotein of old yellow enzyme.

Old yellow enzyme was prepared according to Theorell and Åkeson[12], and the flavin mononucleotide was split from the apoprotein by the method of Warburg and Christian[13]. The recording fluorimeter of Theorell and Nygaard[4] was used in this work.

It was found that no quenching of fluorescence occurred when flavin monosulphate was added to the apoprotein of old yellow enzyme as shown in Fig. 1,*A*. That the protein was capable of combining with flavin mononucleotide with resultant quenching is shown in the same experiment (Fig. 1,*B*). In the latter case, addition of flavin mononucleotide results in an immediate increase of fluorescence followed by a gradual decrease along the kinetic curve produced as the flavin combines with the protein. The association velocity constant (k_1) calculated from these results is in excellent agreement with that found by Theorell and Nygaard[4] under similar conditions. The presence of flavin monosulphate in the reaction mixture did not appear to interfere with the combination of apoprotein and flavin mononucleotide. Similar results were obtained in both phosphate and *tris* buffers at *p*H 7·0.

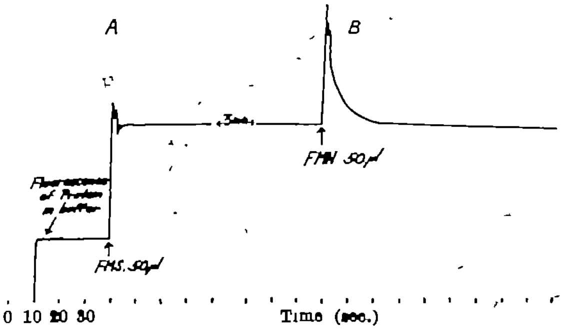

Fig. 1. Comparison of the effect on fluorescence of adding flavin monosulphate (*A*) and flavin mononucleotide (*B*) to apoprotein of old yellow enzyme. Final concentrations: apoprotein, $1 \cdot 1 \times 10^{-6}$ *M* flavin monosulphate and flavin mononucleotide, $0 \cdot 75 \times 10^{-6}$ *M*. The base-line fluorescence of the cell plus apoprotein and buffer is shown at the beginning of the record. Time is marked in 10-sec. intervals

To determine whether the sulphate moiety of flavin monosulphate is able to combine with the sites on the protein where phosphate of flavin mononucleotide ordinarily becomes attached, kinetic studies of the combination of flavin mononucleotide and apoprotein were carried out in the presence of increasing concentrations of flavin monosulphate. No evidence of inhibition of the association reaction of flavin mononucleotide with protein was found, using the highest concentration of the monosulphate (1×10^{-6} *M*) permitted by the fluorimetric technique.

The capacity of flavin monosulphate to combine with old yellow enzyme was then compared with that of riboflavin, since earlier work has shown that riboflavin, at high concentrations, can be partly substituted for flavin mononucleotide[14], forming a complex with a very high dissociation constant[7]. For these experiments, the apoprotein concentration was increased to 9×10^{-6} *M*; riboflavin and flavin monosulphate to 1×10^{-6} *M*. No evidence of fluorescence quenching was obtained with flavin monosulphate, in contrast to the results found with riboflavin.

The finding that replacement of the phosphate by sulphate in the 5′ position of the ribose moiety renders the flavin incapable of binding to the protein provides additional support for the hypothesis of Theorell and Nygaard[6,7] that it is necessary to have both acidic groups of the phosphate of flavin mononucleotide in the anionic form in order that binding may occur. The latter investigators found that the velocity constant for the association of flavin mononucleotide and apoprotein decreases sharply as the acidity of the solution is increased, suggesting that addition of a proton to one of the acidic groups of the phosphoric acid component prevents combination. A similar explanation can be given for the failure of the sulphate residue to be attached to the protein, since it possesses only one free acidic binding site.

The observation that there is apparently no bond formation between the imino NH(3) group of flavin monosulphate and the protein is quite unexpected and more difficult to explain. This is especially so in view of the fact that riboflavin, which lacks a phosphate group, can combine with resultant quenching of fluorescence, although the complex formed is highly dissociated. It must be concluded that the sulphate moiety, in some manner as yet unexplained, hinders binding between the protein and the imino NH(3) group.

Lack of Growth-promoting Activity of Inactivated Penicillin with Turkey Poults

THE growth response of many animals to low levels of dietary antibiotics is now well established. Extensive investigation has not demonstrated the exact mode of action of dietary antibiotic, but it is generally considered that its antibacterial activity is involved. Recently, Taylor and Gordon[1] showed that inactivated penicillin gave an increase in growth-rate of pigs as well as a reduction in the feed-conversion ratio; they suggested that the growth-promoting ability of inactivated penicillin was due to a stable end-product of the inactivated drug.

An experiment was undertaken in this laboratory to determine whether or not inactivated penicillin would stimulate growth in the domestic turkey. Broad Breasted Bronze poults one day old were placed on diets containing: no penicillin, penicillin, penicillin inactivated by autoclaving and by penicillinase. These treatments were carried out with two levels of antibiotic (7 and 14 p.p.m. procaine penicillin) in the turkey starter-ration. The experiment was carried on until the birds were four weeks old, at which time response to antibiotic in the poult has usually passed its peak. Each dietary treatment was replicated three times with sixteen poults of mixed sex per sub-group. Analysis of variance was carried out on the individual body-weights obtained at four weeks old. The results are shown in Table 1. No significant difference at the 5 per cent level of probability existed between birds fed no penicillin and those fed penicillin inactivated by heat or penicillinase. These results were uniform for both male and female poults and for the two levels. The growth response obtained with active penicillin was significant at the 1 per cent level and was of the same order of magnitude as that ordinarily obtained in this laboratory.

Table 1

Dietary treatment	Body-weight (gm., at 4 weeks of age)	
	Males	Females
No antibiotic	543	492
Procaine penicillin, 7 p.p.m.	625	586
Procaine penicillin, 7 p.p.m (inactivated by heat)	553	518
Procaine penicillin, 7 p.p.m. (inactivated by penicillinase)	560	521
Procaine penicillin, 14 p.p.m.	667	555
Procaine penicillin, 14 p.p.m. (inactivated by heat)	563	521
Procaine penicillin, 14 p.p.m. (inactivated by penicillinase)	540	490
	L.S.D. ($P < 0\cdot05$) 39 gm.	L.S.D. ($P < 0\cdot05$), 41 gm.

In order to check the foregoing results, a second experiment was undertaken employing only one level of penicillin (7 p.p.m.). Dietary treatments were otherwise the same as in the first experiment. Each dietary treatment was replicated three times with sixteen poults per sub-group. No significant growth response was noted when inactivated penicillin was added to the ration. As in the first experiment, a significant response was obtained where active penicillin was included in the diet.

The results obtained in the two experiments indicate that, at least for the domestic turkey, penicillin inactivated by either heat or penicillinase will not cause a significant increase in growth.

Effect of Different Dietary Fats on the Fæcal End-Products of Cholesterol Metabolism

INVESTIGATORS in several laboratories, including our own[1], have shown that certain unsaturated fats are able to lower the serum cholesterol-level of human subjects. It is possible that this effect is achieved by an increase in the excretion of the end-products of cholesterol metabolism; hence we have commenced a study of the quantitative changes in these end-products during the administration of different dietary fats. Following the demonstration that ingested cholesterol 4-^{14}C is excreted mainly as cholic acid both in rats[2] and in a human bile fistula patient[3], particular attention was paid to the bile-acid content of the fæces (estimated by the method of Lewis[4]). In addition, the Liebermann–Burchard reacting neutral sterols of the fæces were measured by the method of Abell *et al.*[5] and total fæcal lipid according to van de Kamer *et al.*[6]. The serum cholesterol was also measured by the method of Abell *et al.*[5].

For 12 days, four subjects were fed a basal diet containing 8 gm. of fat and 2,000 calories. Then, in the first pair of subjects, 100 gm. of hydrogenated coconut fat (iodine number 6) was introduced into the diet by isocaloric substitution; after 12–15 days,

Table 1. The Effects of Feeding Hydrogenated Coconut Fat and Sunflower Seed Oil Separately. Mean Figures are Given for the Four Subjects, although the Order of Feeding of the Fat and the Oil was Reversed in Paired Subjects (see Text)

	Basal period 8 gm. of fat/24 hr. (12 days)	Hydrogenated coconut fat 100 gm./24 hr. (12–15 days)	Sunflower seed oil 100 gm./24 hr. (12–15 days)
Serum cholesterol (mgm. per cent)*	119	168	93
Fæcal lipid (gm./24 hr.)	1·8	5·7	7·2
Fæcal neutral sterols (mgm./24 hr.)	390	680	880
Fæcal bile acids (mgm./24 hr.)	142	127	258

* The basal figure is the mean of four readings per subject; all other figures are of the serum cholesterol at the end of each feeding period.

this was replaced by 100 gm. of sunflower seed oil (iodine number 135) for a similar period. In the other two subjects, the dietary fats were administered in the reverse order. The results are summarized in Table 1.

A second investigation was conducted on a further three subjects. After 10 days on a basal diet of 2,500 calories and 8·25 gm. of fat, 75 gm. of hydrogenated coconut fat was added to the diet. After 10 days, the diet was further supplemented by 75 gm. of sunflower seed oil, and this was continued for 20 days. Finally, the sunflower seed oil was withdrawn, and for the last 10 days only the hydrogenated coconut fat supplement was fed. The results are summarized in Table 2.

In all seven subjects, when hydrogenated coconut fat was fed alone, the serum cholesterol rose. When sunflower seed oil was fed before, in addition to, or after the fat, there was a fall in the serum cholesterol level. Administration of either fat produced an increase in total fæcal lipid. This was somewhat more marked with sunflower seed oil than with the hydrogenated coconut fat, but at all times the absorption of dietary lipid was more than 93 per cent. The fæcal neutral sterols also were increased when hydrogenated coconut fat was fed and were further increased by sunflower seed oil. This may partly reflect the relative content of Liebermann–Burchard reacting sterols in the two fats (303 mgm. per cent in hydrogenated coconut fat and 751 mgm. per cent in sunflower seed oil). Of particular interest were the changes in fæcal bile-acid excretion; there was virtually no change from basal level when hydrogenated coconut fat was fed alone; with the introduction of sunflower seed oil, both by addition and substitution, fæcal bile-acid excretion almost doubled.

Table 2. The Effects of Feeding Hydrogenated Coconut Fat Alone and Together with Sunflower Seed Oil. Mean Results in Three Subjects

	Basal period 8·25 gm. of fat/24 hr. (10 days)	First hydrogenated coconut fat period 75 gm./24 hr. (10 days)	Hydrogenated coconut fat 75 gm./24 hr + sunflower oil 75 gm / 24 hr. (20 days)	Second hydrogenated coconut fat period 75 gm./24 hr. (10 days)
Serum cholesterol (mgm. per cent)*	113	152	136	161
Fæcal lipid (gm./24 hr.)	2·7	4·1	6·7	4·2
Fæcal neutral sterols (mgm./24 hr.)	663	843	993	766
Fæcal bile acids (mgm./24 hr.)	128	153	333	136

* The basal figure is the mean of three readings per subject; all other figures are of the serum cholesterol at the end of each feeding period.

In these experiments, therefore, the fall in serum cholesterol-level induced by sunflower seed oil has been associated with an increase in bile-acid excretion. These preliminary data are consistent with the tentative hypothesis that in exerting its effect on the serum cholesterol, sunflower seed oil promotes the catabolism of this sterol and its excretion from the body.

A New Type of Carcinostatic Agent

There are various ways of approaching the cancer problem. One way is to attempt to find substances which will prevent mitosis. For if cancer is due to uncontrolled cell division, the inhibition of cell division by relatively harmless substances would be a means of combating the disease. For some years it has been argued that the initiation of cell division is due to a clotting reaction in the protoplasmic colloid, a reaction that leads to the formation of the mitotic spindle, and it has been urged that anti-clotting agents can successfully inhibit cell division. The evidence for this point of view has been summarized in a recent monograph[1]. Heparin can prevent cell division, but for one reason or another it is not a highly successful agent in retarding the growth of a tumour. Extracts of ovaries are more potent antimitotic agents[2], and indeed such extracts obtained from the ovaries of various invertebrates, from the ovaries of many fishes, and from the ovaries of amphibians and mammals can keep protoplasm fluid and thus prevent the mitotic gelation which is a necessary precursor of the division of the cell.

For several years we have prepared extracts from cow ovaries in the hope that such extracts would prove to have carcinostatic activity. Our early experiments gave somewhat variable results, and sometimes indeed the extracts we prepared hastened, rather than prevented, the death of animals with implanted tumours. For that reason we tried in various ways to purify our crude extracts so that they would be more potent both as antimitotic agents and as carcinostatic agents.

For a long time we were unsuccessful, and in the somewhat purer preparations we obtained by a number of standard procedures, both the antimitotic and carcinostatic action were lost. Then about a year ago, we tried fractional precipitation of our crude extracts in the cold with various concentrations of alcohol. A fraction obtained with an intermediate concentration of alcohol (45–60 per cent) retained antimitotic potency. This fraction, though soluble with difficulty in sea water, had a clear-cut antimitotic action on eggs of the worm *Chaetopterus*, and studies of protoplasmic viscosity showed that, in the eggs exposed to dilute solutions of this fraction, the mitotic gelation was completely inhibited. Also this fraction when dissolved in sea water prevented cell division in eggs of the clam *Spisula*.

During the past year we have experimented with more than four thousand mice, all implanted with Ehrlich ascites tumours. Among the control, untreated mice, only 1 per cent of the animals survived, and these in so far as we could determine were cases in which proper inoculation had not been made. On the other hand, precipitates obtained with intermediate concentrations of alcohol were potent carcinostatic agents for the very lethal type of tumour that we were using. In one instance, an extract had no activity but other extracts were effective, and 15–25 per cent of the mice treated with saline solutions containing the fractions obtained with intermediate concentrations of alcohol survived indefinitely.

Details of our experiments will be presented elsewhere. Thus we expect to publish the first of a series of papers in the immediate future[3]. Since this paper was written, changes in our methods of extraction and purification have yielded even more impressive results with higher percentages of survival than those noted above. These later experiments are now being repeated, and will be reported as soon as we know more about them.

The work reported here in preliminary fashion was supported by grants from the American Cancer Society, the National Cancer Institute and the National Science Foundation.

Innervation of the Lamellibranch Muscle

Little seems to be known regarding the innervation of the lamellibranch muscles, especially of the adductors. J. Bowden and J. Lowy[1] found nerve fibres and nerve endings in the muscles (Ranvier's gold chloride method), but as they state: "the results were never really satisfactory". They found methylene blue staining adequate to detect the larger trunks and to trace their course, but the process, by their own admission, is "useless for showing details of innervation". As to other methods of impregnation used, Bowden and Lowy state: "no nerve elements could be stained" in this region.

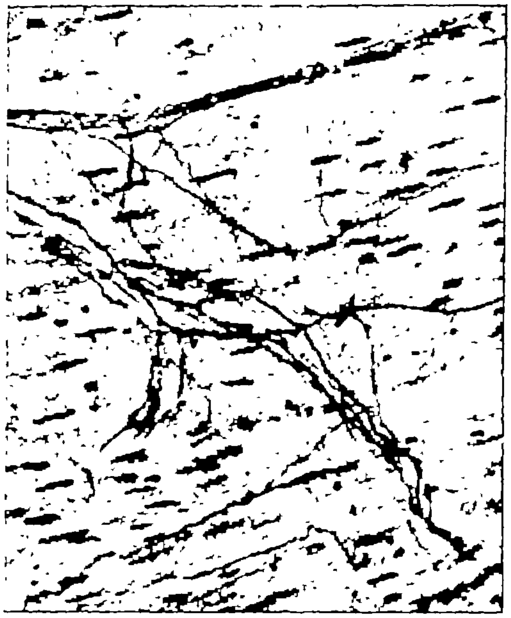

Fig. 1. *Unio* adductor. Nerve-plexus. Bielschowsky–Abrahám method (× 120)

We have succeeded in revealing the innervation, even down to details, of the adductors of *Unio* and *Anodonta*.

The nervous system of muscles of these lamellibranchs can be detected by Abrahám's modification of Bielschowsky's method[2]. By means of this modification, not only the small and large trunks, branches and plexuses are shown up, but also the close connexion of the single nerve fibres with the muscle fibres can be fairly well demonstrated. Within the plexuses there is neither anastomosis nor reticulum[3]; in the end plexuses the single fibres are independent, with no terminal reticulum (Fig. 1).

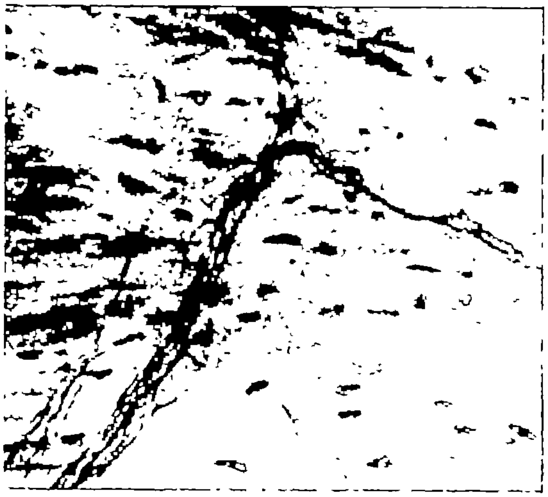

Fig. 2. *Unio* adductor. Nerve-plexus. Thick and thin nerve fibres. Bielschowsky–Abrahám method (× 120)

In our opinion, the appearances reported by Bowden and Lowy as multipolar and unipolar nerve cells are not nerve cells, but artefacts. This view is supported by the results of extirpation of the cerebral and visceral ganglions respectively; it is stated that after 60–70 hr., the nerve fibres of the adductors begin to degenerate and later disappear. If there were nerve cells in the adductors, only partial degeneration could occur, since removal of the ganglions would leave the assumed nerve cells and processes intact. Our photomicrographs show that there is no 'intrinsic' nervous system in the adductors.

Plexuses of different size and density consist of two kinds of fibres (Fig. 2). Both are richly branched, but without anastomosis. The extremely fine branches can be followed for a good distance, but they gradually become thinner and disappear without any special formations, as reported by A. Brück[4], and by Bowden and Lowy[1]. Quite fine granules or knobs can be observed at the ends of certain fibres with high-power magnification.

Statements that the nerve fibres run parallel to the longitudinal axis of the muscle fibres are based on erroneous observations. We find that, with a few exceptions, the nerve trunks and branches form an angle with the longitudinal axis of the muscle fibres; in our opinion the parallel fibres reported by Bowden and Lowy are not nerve fibres.

The myristoylcholine method of G. B. Koelle[5] is not suitable for demonstrating the innervation of lamellibranch muscles. The results of our investigations will be published in detail elsewhere.

A Lipid Material in Bone and Teeth in Experimental Chronic Fluorosis

IN experimental chronic fluorosis and in spontaneous fluorosis in man[1], many authors have observed peculiar dark blue granules in paraffin and celloidin sections of decalcified bone and teeth stained with hæmatoxylin-eosin (Fig. 1). It has been suggested that these could be either calcium fluoride[2,3] or merely a pathological calcification[4,5]. Examination of powdered material[6] from bone and teeth (rat), using X-ray diffraction, failed to detect any calcium fluoride. (The method used permitted detection of 0·5 per cent or more calcium fluoride in bone powder.)

Histochemical tests have shown that the granules appear periodic acid–Schiff positive. They do not stain metachromatically with toluidine blue, and the methylene blue extinction occurs about pH 3. Using phase-contrast microscopy (positive) they appear as glistening particles. Various sudan dyes in different solvents used on the decalcified paraffin sections show that the granules do not take up the red dyes, but very readily take up sudan black *B* dissolved in 70 per cent ethyl alcohol. After extraction with pyridine, there is no uptake of sudan black *B* though the outline of the extracted granules is still visible.

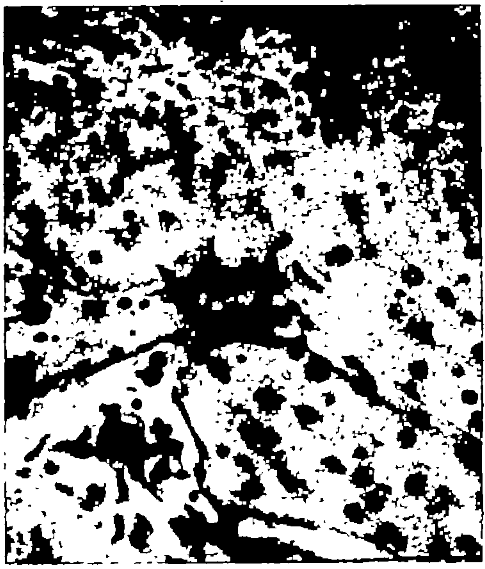

Fig. 1. Granules in terminal plate of epiphysis from rat femur. Decalcified paraffin section. Hæmatoxylin-eosin (× c. 200)

It is therefore suggested that the granules seen in decalcified paraffin sections consist mainly of a lipid material.

Further investigations using histochemical and X-ray diffraction methods are in progress.

Colour Vision of Achromats' Parents

Two achromats, a woman student and a man student, were recently tested for colour vision. Both proved to be of the so-called pure rod-vision type[1], completely lacking in hue discrimination, with marked photophobia, nystagmus and central scotoma in photopic vision, and both had been totally colour blind since infancy.

Since there is evidence that red–green colour vision major defects often have heterozygous manifestations[2], we tested the parents of these achromats with the anomaloscope. Tables 1 and 2 summarize the

Table 1. THE ACHROMATS' FATHERS

	Red–green test	Yellow–blue test
Man's father (age 62)	Green deviation . frequency, 12/209 men Matching range frequency, 24/209 men	Deviation not abnormal Matching range normal
Woman's father (age 58)	Green deviation : frequency, 42/209 men Matching range : frequency, 14/209 men	Deviation not abnormal Matching range : frequency, 24/209 men

Table 2. THE ACHROMATS' MOTHERS

	Red–green test	Yellow–blue test
Man's mother (age 58)	Deviation not abnormal Matching range: normal	Deviation not abnormal Matching range: frequency, 8/213 women
Woman's mother (age 58)	Red deviation: frequency, 18/231 women Matching range: frequency, 9/213 women	Deviation not abnormal Matching range: frequency, 8/213 women

results, comparing the frequencies of the parent's abnormalities with those found in a standard population[3].

It will be seen that both fathers had abnormal green deviations and red–green matching ranges, but that the enlarged matching range of the woman's father was their only yellow–blue defect, although their ages were 62 and 58.

The woman achromatope's mother had an abnormal red deviation and red–green matching range, but the man's mother was normal in red and green. The mothers had no abnormal yellow–blue deviations, although both their ages were 58, but each had an abnormal yellow–blue matching range.

Although only four parents of achromats were tested, a number of infrequent differences from the normal were found, and these results suggest that tests on a larger number of the near relatives of achromats might confirm the suspicion that this defect has a tendency towards heterozygous manifestation. Both achromats were only children.

Thanks are due to the achromatopes (Miss Gwen Jones and Mr. Colin B. Blakemore) and to Dr. Peter McKellar (of Sheffield) and Mr. George Westby (of Hull).

Tactic Movements in *Chlamydomonas moewussi*

SPECIES of *Chlamydomonas* are generally regarded as phototactic[1]. For a study of certain aspects of phototaxis, *Chlamydomonas moewussii* (Pringsheim collection 11–16 *g*) was cultivated on a medium described by Hutner and Provasoli[2]. The algae in their culture medium were placed in cuvettes which were illuminated from the side. Under these conditions, phototactic algae move rapidly to the illuminated side of the cuvette. The species studied showed no such phototaxis, but invariably moved to the water–gas interface. If the cuvettes were covered with olive oil, the algae moved through the oil layer to the interface. The gas phase was therefore altered. Square glass cuvettes (v. 35 ml.) were filled with 15 ml. algal suspension and fitted with rubber stoppers with in and outlet tubes. The gas phase (20 ml.) of each cuvette was flushed with 2 litres of gas mixture and the cuvettes then closed. The cuvettes were then placed under conditions of unilateral illumination. In parallel experiments, algae of the same age and culture were used. Table 1 summarizes the results of the different treatments.

Table 1. EFFECT OF FLUSHING GAS PHASE WITH VARIOUS MIXTURES AND OBSERVING BEHAVIOUR OF ALGAE AFTER 24 HR. IN CLOSED SYSTEM

Gas phase Illumination	Air	Nitrogen	Air + 50 per cent CO_2	Air + 75 per cent CO_2	100 per cent CO_2	Gas and liquid flushed with CO_2-free air
300 ft.-candles	+ +	+	+ +	+ +	+ +	–
1,000 ,,	+ +	+	+ +	–	–	–

+ +, strong tactic movement to water–gas interphase.
+, slight tactic movement to water–gas interphase.
–, settling out.

When the gas phase was flushed with nitrogen, the tactic movement became less marked, but still existed. When the gas phase was swept out with carbon dioxide-free air and in addition the stream was bubbled vigorously through the solution for some time, there was complete settling out of the algae, when the algae were left in the closed cuvettes.

Flushing the gas phase with air containing various amounts of carbon dioxide led to unexpected results. At concentrations up to 50 per cent carbon dioxide, there was marked taxis towards the air–water interface at all light intensities. With more than 50 per cent carbon dioxide, however, at 75 per cent and 100 per cent, the algae settled out when exposed to light intensities of 1,000 ft.-candles and more. When the algae were exposed at the same concentration of carbon dioxide to 300 ft. candles, there was no settling. Moreover, transfer of algae exposed to 300 ft.-candles and 100 per cent carbon dioxide for one day to 1,000 ft.-candles did not cause subsequent settling. In all cases when there was settling out, the algae recovered if re-exposed to air after 24 hr. This recovery was characterized by redistribution of the algae throughout the medium with some concentration at the water–air interface. Apparently, recovery of lost motility is involved in this process.

The lack of taxis when all carbon dioxide is swept out from gas and medium, and the decreased taxis when carbon dioxide is removed from the gas phase but not from the medium, points to the correlation of tactic movement to the presence of carbon dioxide. It appears that the *Chlamydomonas* species studied shows taxis towards carbon dioxide.

The reason for the difference in behaviour at different light intensities is not clear. *p*H cannot have been a factor, as the conditions were identical for the two light treatments. However, the temperature at 1,000 ft.-candles was higher than that at 300 ft.-candles. Air controls showed no settling, nor did the lower concentration of carbon dioxide. It is possible that the settling out effect was a combination of higher concentration of carbon dioxide and raised temperatures.

Polyhedral Shape of Adenovirus Particles as shown by Electron Microscopy

Crick and Watson[1] suggested that a small virus particle contains identical protein sub-units packed together with cubic symmetry, and they went on to predict from this that the virus particle itself might be polyhedral. Electron micrographs have since shown that various viruses do give hexagonal images. This is clearly the case, for example, for the plant virus of turnip yellow mosaic[2] and for an insect virus that infects the larvæ of the crane fly[3]. We now report finding a similar hexagonal shape for the particles of adenovirus which is a human pathogen.

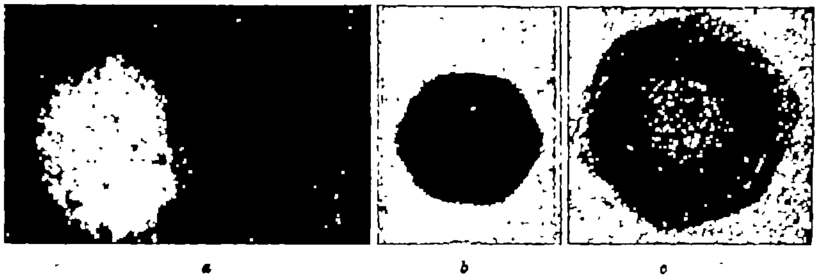

Fig. 1. Electron micrographs of adenovirus particles (type 6) from infected HeLa cell cultures. *a*, a particle shadowed with platinum (× 280,000); *b*, a particle treated with phosphotungstic acid (× 250,000); *c*, a particle replicated with carbon (× 280,000)

Suspensions of this virus were prepared from large pools of HeLa cell cultures of high infectivity and were concentrated by differential centrifugation. The virus particles when fixed with osmium tetroxide and metal-shadowed (Fig. 1,*a*) gave images which did not clearly differ from those of spherical objects apart from a suggestive angularity in the shadows. Similarly, the virus particles in sections of infected HeLa cells shown in the excellent electron micrographs of Morgan, Howe, Rose and Moore[4] were described as round. On the other hand, Brandon *et al.*[5] have reported that the images of some of the particles found in their suspensions appeared to be five-sided. When we increased the electron density of the osmium tetroxide fixed virus particles by treating them further with 1 per cent phosphotungstic acid, it was seen that in fact the particles have a clearly hexagonal image (Fig. 1,*b*). This appearance was confirmed by making carbon replicas of the surface of formalin fixed particles (Fig. 1,*c*) using the method of Bradley[6]. In this latter procedure the particles themselves were removed from the replica with concentrated sodium hydroxide.

As judged from the electron micrographs of phosphotungstic acid treated preparations, the virus particles have a uniform size of about 700 A. and each gives a similar six-sided image however it happens to be orientated on the supporting film. We therefore assume that the particles have a symmetrical polyhedral form. Of the possible shapes, only two are consistent with the hexagonal appearances seen in our electron micrographs, the rhombic dodecahedron (a solid with twelve identical rhombic faces) and the icosahedron (twenty faces, each an equilateral triangle).

By metal-shadowing the phosphotungstic acid treated preparations, it was possible to obtain clear shadows without masking the hexagonal outline of the virus; the shadows varied from pointed to flat-topped, depending on the orientation of the particles. Models of the rhombic dodecahedron and the icosahedron were then used in an attempt to identify the shape consistent with these appearances, but it was found that neither model threw a shadow so characteristic that it could not be closely matched by a suitable orientation of the other. Thus it was not possible to draw a precise conclusion from the metal-shadowed preparations as to the exact shape of the virus. So far, replicas have also failed to show unequivocally whether the faces are rhombic or triangular.

The regular shape of the particles is allied to a remarkable resistance to attack with proteolytic enzymes (trypsin, pepsin and papain) and both nucleases, procedures that almost entirely digest vaccinia[7], influenza and similar viruses[8,9].

Technical assistance with the electron microscopy was given by Mr. O. Green and Miss Janet Lawrence.

The Polyhedral Virus of *Heliothis armigera* (Hbn.)

With reference to the communication by Dr. G. H. Bergold and Dr. W. E. Ripper on the polyhedral virus of *Heliothis armigera*[1], it has evidently escaped their notice that the virus of this nuclear polyhedral disease has already been isolated and characterized on the electron microscope. Furthermore, experiments in the use of this virus in the control of the American cotton bollworm in Uganda are now actively in progress in collaboration with Mr. T. H. Coaker, of the Empire Cotton Growing Corporation[2].

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, November 4

Faraday Society (in the Main Lecture Theatre, Chemistry Department, Imperial College, London, S.W.7), at 5 p.m.—Prof. W. Jost (University of Göttingen). "Crystal Defects, Especially Near Phase Transitions"* (Bourke Lecture).

North East Coast Institution of Engineers and Shipbuilders (in the Lecture Theatre of the Literary and Philosophical Society, Newcastle-upon-Tyne), at 6.15 p.m.—Dr. S. Livingston Smith and Dr. J. H. Richards: "Nuclear Power for the Propulsion of Merchant Ships".

Society of Chemical Industry, London Section (joint meeting with the Food Group, at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Dr. J. R. Nicholls, Dr. J. Williams, Mr. R. D. Mason and Dr. F. H. Banfield: "Technological and Analytical Problems involved in the Use of Food Additives".

Tuesday, November 5

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. R. A. French: "The Changing Landscape of the Soviet Union" *

Institution of Chemical Engineers (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 5.30 p.m.—Dr. R. P. Linstead, C.B.E., F.R.S.: "An Education for Our Times?" (Ninth Hinchley Memorial Lecture).

Institution of Civil Engineers (at Great George Street, London, S.W.1), at 5.30 p.m.—Sir Arthur Whitaker: Presidential Address.

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W.C 2), at 5.30 p.m.—Scientific Papers

Society for Analytical Chemistry (in the Lecture Theatre of the Royal Institution, 21 Albemarle Street, London, W.1), at 6.30 p.m.—Dr Rudolf Přibil (Czechoslovak Academy of Sciences): "Recent Developments in Chelatometry".

Society of Chemical Industry, Plastics and Polymer Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. C. H. Bamford: "Synthetic Polypeptides as Protein Models".

Wednesday, November 6

Physical Society, Colour Group (at the Institute of Ophthalmology, Judd Street, London, W.C.1), at 3.30 p.m.—Mr. H. A. Jobbins: "Colour and Geology"; Mr. B. W. Anderson: "Gems".

Institute of Petroleum (at 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. G. Chandler and Mr. D. W. Lindsell. "Cyclical Fluctuations and Black Oil Demand—an Introduction".

Women's Engineering Society, London Branch (at the Central Electricity Authority Headquarters, Winsley Street, London, W.1) at 6.45 p m.—Mr D. W. S. Limbert· "Meteorological Aspects of the International Geophysical Year".

Thursday, November 7

Chemical Society (joint meeting with the Fine Chemicals Group of the Society of Chemical Industry, in the Large Chemistry Lecture Theatre, University College, Gower Street, London, W.C.1), at 2.15 p.m.—Symposium on "Newer Preparative Methods in Organic Chemistry".

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. Wilson Smith, F.R.S.: "Virus-Host Cell Interactions" (The Leeuwenhoek Lecture).

Bone and Tooth Society (at the Institute of Orthopedics, 234 Great Portland Street, London, W.1), at 5 p.m.—Symposium on "Sulphate Metabolism in Bone and Connective Tissue". Dr. S. R. Pelc: "Sulphate Metabolism in Cartilage as Indicated by Autoradiographs"; Dr. H. Kodicek: "Vitamin C and Sulphate Metabolism of Connective Tissue Mucopolysaccharides"; Dr. R. C. Curran: "Sites of Formation of Sulphated Mucopolysaccharides in Connective Tissues".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. A. Bogdan: "Flowering Habits of Rhodes Grass"; Prof. Tom Harris, F.R.S.: "A Burnt Mesozoic Flora of South Wales"; Major J. P. T. Burchell. "The Sub-aerial Loams of Post-glacial Times and their Molluscan Content as Evidenced in Kent".

Institute of Refrigeration (at the Junior Institution of Engineers, Pepys House, 14 Rochester Row, Westminster, London, S.W.1), at 5.30 p.m.—Dr. W. Summer: "A Review of Methods for Odour Control in Refrigerated Space".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion of the Report on "The Supply and Training of Teachers for Technical Colleges".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C.1), at 5.30 p m.—Dr. H. Lehmann. "Variations in Haemoglobin Synthesis".* (Seventh of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation. Further lectures on November 12, 14, 19, 21, 26, 28 and December 3 and 5.)

Institute of Physics, Stress Analysis Group (in the Department of Civil and Municipal Engineering, University College, Gower Street, London, W.C.1), at 6 p.m.—Discussion on "Photoelastic Reflection Techniques" introduced by Dr. H. Fessler and Mr. D. J. Haines.

Institute of Metals, London Local Section (at the Royal School of Mines, South Kensington, London, S.W.7), at 7 p.m.—Dr. J. White: "Refractories".

Royal Institute of Chemistry, London Section (joint meeting with the Brunel College of Technology Scientific Society, at the Brunel College of Technology, Woodlands Avenue, Acton, London, W.3), at 7 p.m.—Dr. R. Spence: "Some New Instruments Developed at Harwell".

Thursday, November 7—Friday, November 8

National Association for Mental Health (at the Central Hall, Oldham Street, Manchester).—Conference on "The Challenge of Mental Deficiency".

Friday, November 8

British Glaciological Society (in Lecture Room 4, The University, Edgbaston, Birmingham), at 5 p.m.—Mr. R. G. West: "The Glacial Period in East Anglia".

Institution of Mechanical Engineers (in conjunction with the British Nuclear Energy Conference, at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Dr. H. Kronberger: "Vacuum Techniques in the Atomic Energy Industry".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof Geoffrey Gee, F.R.S.· "New Ways with Large Molecules".

Saturday, November 9

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Miss Christina Hole: "Witchcraft in England".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer in Chemistry; Assistant Lecturer in Physics; Assistant Lecturer in Botany; Assistant Lecturer in Zoology; a Laboratory Technician in Chemistry; and a Laboratory Technician in Botany and Zoology, in the Faculty of Science, National University of Libya, Tripoli—The Director, Personnel Department, British Council, 65 Davies Street, London, W.1, quoting "N.4 (57)" (November 8).

Reader in Physical Metallurgy; a Reader in Industrial Metallurgy; and a Reader in Electrical Engineering (Heavy Current)—The Registrar, College of Technology, Suffolk Street, Birmingham (November 11).

Shell B.P. Research Fellow in the Department of Aeronautical Engineering—The Secretary and Registrar, The University, Southampton (November 11)

Lecturer or Assistant Lecturer in Psychology—The Registrar, The University, Hull (November 15).

Lecturer (with an honours degree in zoology) in the Department of Zoology, Canterbury University College, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, November 15).

Electrical Engineer/Physicist in the Department of Physics, to supervise the operation of a 6-MeV. van de Graaf machine, and to develop associated research equipment—Prof. Samuel Devons, The Physical Laboratories, The University, Manchester 13 (November 16).

Assistant Librarian—The Secretary, The University, Aberdeen (November 19).

Lecturer (Grade II) in Geochemistry within the Department of Geology—The Registrar, The University, Bristol (November 20)

Senior Lecturer or Lecturer in Philosophy at the University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 20).

Reader (academically qualified and able to promote research and conduct postgraduate lecture courses) in Control Engineering—The Clerk to the Governing Body, Battersea College of Technology, London, S.W.11 (November 22).

Assistant Lecturer (preferably with a special interest in inorganic chemistry) in Chemistry—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (November 23).

Inorganic Chemist, Scientific Officer/Senior Scientific Officer grade (with a first- or second-class honours degree in chemistry, or equivalent), at the National Physical Laboratory (Metallurgy Division), Teddington, Middlesex, for work which includes the investigation of new techniques, including mass spectrometry and activation analysis—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.243/7A (November 23).

Harrison Chair of Mechanical Engineering—The Registrar, The University, Liverpool (November 30).

Research Assistant (with an honours degree in biochemistry or pharmacology) in the Department of Pharmacology and Therapeutics, to work on the effect of hypoglycaemic drugs on carbohydrate metabolism—The Department of Medicine, Queen's College (University of St. Andrews), Dundee (November 30).

Scientific Officer (with an honours degree in zoology (or botany, plant pathology), in the Nematology Department, for field and laboratory work on pea root eelworm—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (November 30).

Lecturer in Physical Chemistry or Inorganic Chemistry at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 6).

SENIOR LECTURER (preferably with qualifications in the general field of modern algebra or topology) IN MATHEMATICS at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 16).

CHAIR OF EXPERIMENTAL PATHOLOGY in the John Curtin School of Medical Research, Australian National University, Canberra—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1

CONTROL OFFICER (preferably single, with a good general education and agricultural training or knowledge of surveying, mapping, entomology or botany) IN THE NORTHERN NIGERIA GOVERNMENT Medical Department—The Crown Agents, 4 Millbank, London, S.W.1, quoting M.34/43728/NF.

ENTOMOLOGIST (with a good honours degree and a keen interest in applied entomology), to develop and apply laboratory techniques for investigating the biological activity of insecticides and spray deposits—The Secretary, East Malling Research Station, near Maidstone, Kent.

LECTURER IN INORGANIC CHEMISTRY for higher national certificate and Grad.R.I.C. courses, at Coventry Technical College—The Director of Education, New Council Offices, Coventry.

LECTURER (with a special interest in applied chemistry) IN THE CHEMISTRY DEPARTMENT; and a SENIOR LECTURER, LECTURER, and ASSISTANT (Grade B) IN THE PHYSICS DEPARTMENT—The Principal, Royal Technical College, Salford

LECTURER (with special qualifications in inorganic chemistry and/or physical chemistry) IN CHEMISTRY—The Secretary, Royal College of Science and Technology, Glasgow.

PHYSICIST or ELECTRICAL ENGINEER (with special qualifications in advanced electronics) IN THE DEPARTMENT OF PHYSICS, to assist with the building of a precision mass spectrometer—The Registrar, King's College (University of Durham), Newcastle-upon-Tyne.

PHYSICISTS and ELECTRICAL ENGINEERS (young graduates) IN THE PHYSICS DEPARTMENT in London, to work on the development of new techniques applicable to the iron and steel industry (instrumentation and automatic control; development and application of new inspection and control techniques to steel work processes)—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "P.Y.4"

PLANT PATHOLOGISTS (male, between 25 and 35 years of age, with a good honours degree in agriculture or natural science and at least one years postgraduate training in mycology and plant pathology, and preferably a knowledge of virus diseases) IN THE DEPARTMENT OF AGRICULTURE, Tanganyika, for field and laboratory work in the diagnosis and investigation of fungal and bacterial diseases of crop plants and the testing of control measures—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/8/03.

SENIOR LECTURER IN CHEMISTRY; SENIOR LECTURER IN INDUSTRIAL ADMINISTRATION; SENIOR LECTURER IN METALLURGY; SENIOR LECTURER IN PHARMACEUTICAL CHEMISTRY; SENIOR LECTURER IN PHARMACOLOGY; SENIOR LECTURER IN TECHNOLOGY OF DYEING; SENIOR LECTURER IN TEXTILE PHYSICS; LECTURER IN CHEMISTRY; LECTURER IN CHEMICAL ENGINEERING; LECTURER IN ELECTRICAL ENGINEERING; LECTURER IN MATHEMATICS; LECTURER IN PHARMACOGNOSY; LECTURER IN PHYSICS; LECTURER IN OPHTHALMIC OPTICS; LECTURER IN RAYON TECHNOLOGY AND TEXTILE CHEMISTRY; LECTURER IN TECHNOLOGY OF DYEING; and a LECTURER IN TEXTILE ENGINEERING—The Registrar, Institute of Technology, Bradford 7.

SENIOR LECTURER (with considerable practical experience in the rubber industry and professional and/or academic qualifications) IN RUBBER TECHNOLOGY; a SENIOR LECTURER (with laboratory experience in research and/or industrial organizations dealing mainly with rubbers) IN PHYSICAL TESTING OF POLYMERS; a LECTURER (qualified young engineer prepared to treat rubber as an engineering material, particularly in dynamic applications) IN RUBBER ENGINEERING, and a LECTURER (science graduate prepared to teach polymer chemistry and to work on colloid dispersions) IN POLYMER CHEMISTRY—The Clerk to the Governors, National College of Rubber Technology, Holloway, London, N.7.

SENIOR RESEARCH ASSISTANT (with postgraduate experience in the mechanics of solids, particularly elasticity) IN THE DEPARTMENT OF MINING ENGINEERING, to work on the theoretical analysis of ground movements in mining, under the supervision of the Professor of Applied Mathematics—The Registrar, The University, Nottingham.

STATISTICIAN (with a good honours degree in mathematics or statistics), for biometrical research and consultation in the Section of Statistics—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, quoting Ref. 57/9.

What do you look for in a polarized relay?

- ✳ High electro-magnetic sensitivity
- ✳ Large winding space: High copper efficiency
- ✳ Symmetrically balanced movement
- ✳ High thermal and shock stability
- ✳ Low susceptibility to magnetic interference

The Ericsson miniature polarized relays incorporate all of these features and many more. Whether your particular application calls for each-side stable, one-side stable or centre stable, these are the relays that will give you trouble-free running for many millions of operations. They are also ideally suited for chopper applications for D.C. amplifiers. Write now for Pamphlet P.5682 which gives full details.

LECTURES AND COURSES

UNIVERSITY OF BIRMINGHAM

FACULTY OF SCIENCE

M.Sc. Courses in Radioactivity

A course of lectures and practical work in general radioactivity leading to the degree of M.Sc. by examination is available in the Department of Physics. The course is suitable for honours graduates in physics or related subjects wishing to obtain special experience in radioactive techniques including radiochemistry.

M.Sc. Course in Reactor Physics and Technology

A course of lectures and practical work in Reactor Physics and Technology leading to the degree of M.Sc. by examination is available in the Faculty of Science. The course is suitable for graduates with a good degree in pure or applied science (normally Physics, Metallurgy, Mechanical Engineering, or Chemical Engineering). Some introductory lectures and tutorial assistance will be provided to bring entrants to the necessary standard of knowledge in relevant branches of both physics and engineering.

These courses will last for one academic year, the fee is £81. Graduates wishing to be considered for the Advanced Course Studentships of the Department of Scientific and Industrial Research must apply to the Registrar, University of Birmingham, before February 1, 1958. The University may be able to make maintenance awards in special circumstances. Applications for admission to the courses starting in October, 1958, and requests for further information, should be made as soon as possible to the Registrar.

MIDDLESEX COUNTY COUNCIL EDUCATION COMMITTEE

BRUNEL COLLEGE OF TECHNOLOGY
WOODLANDS AVENUE, ACTON, W.3

A course in "Basic Electronics" extending over about 25 weeks will be held on Tuesday evenings from 6.30 to 9.30 p.m., commencing November 12, 1957. Fee £2.

Further particulars may be obtained from the Principal.

C. E. GURR, M.Sc., Ph.D.,
Secretary to the Education Committee.

MIDDLESEX COUNTY COUNCIL EDUCATION COMMITTEE

BRUNEL COLLEGE OF TECHNOLOGY
WOODLANDS AVENUE, ACTON, W.3
DEPARTMENT OF CHEMISTRY
COURSE IN ADVANCED CHEMISTRY AND TECHNOLOGY OF WAXES

Lectures and practical work extending over 30 weeks on Thursdays, commencing on November 14, 1957, from 5.30 to 9.30 p.m. Fee £3.

Further particulars may be obtained from the Principal

C. E. GURR, M.Sc., Ph.D.,
Secretary to the Education Committee.

UNIVERSITY COLLEGE LONDON

FREE PUBLIC LECTURES, AUTUMN TERM, 1957

Friday, November 8 at 5.30, Professor J. Konorski, "New Data Concerning the Functions of the Prefrontal Areas in Animals."

Monday, November 25, December 2, 9, at 5, Dr. H. Harris, "Human Biochemical Genetics"

Details of all public lectures (including lunch-hour lectures), from Publications Officer, University College London, Gower Street, W.C.1. (Stamped envelope required).

OFFICIAL APPOINTMENTS

UNIVERSITY OF LEEDS

DEPARTMENT OF ANAESTHETICS

Applications are invited from candidates interested in physiology, physics or biochemistry for appointment as full-time Research Assistant in the Department of Anaesthetics at a salary within the range £500 to £600 a year. The appointment is suitable for a science graduate intending to work for a higher degree and will be for one year in the first instance subject to renewal. Laboratory facilities will be provided and the successful applicant will work as part of a group engaged in studying the problems of spontaneous and artificial respiration in man.

Applications (three copies), stating date of birth, qualifications and experience, together with the names of two referees, should reach the Registrar, the University, Leeds, 2 (from whom further particulars may be obtained), not later than November 25, 1957.

SENIOR SCIENTIFIC OFFICER

A vacancy exists with the Chemical Services Department of the Operations Branch of the Industrial Group of the United Kingdom Atomic Energy Authority at Springfields Works, Salwick, Preston, Lancashire, for a chemist to lead a team engaged on inorganic analytical research and development work arising from chemical and metallurgical production and research programmes in connection with the rarer metals. Applicants must have at least a second-class honours degree in chemistry or hold equivalent qualifications and have had experience in the application of the physico-chemical techniques used in modern analytical methods. Experience in emission spectroscopy would be an advantage. Candidates should be at least 26 years of age and preferably have had experience of leading a small development team. Salary will be assessed within the scale £1,215 to £1,425. A contributory pension scheme is in operation. A house for renting by the successful candidate, if married, may be available in due course, or alternatively, substantial assistance may be given towards legal expenses incurred in private purchase.

Send postcard for application form, quoting reference 2101, to Works Secretary, Springfields Works. Closing date, November 25, 1957.

WELSH COLLEGE OF ADVANCED TECHNOLOGY

Principal: A. Harvey, Ph.D., B.Sc., F.Inst.P.
ENGINEERING DEPARTMENT

Applications are invited for three posts as Lecturer at a salary of £1,200 by £50 to £1,350. Two posts are in Mechanical Engineering and one is in Production Engineering. Applicants should hold appropriate academic and/or professional qualifications and have had sound industrial experience. Duties to commence at a date to be arranged.

Forms of application, together with further particulars, may be obtained from the Principal on receipt of a stamped addressed foolscap envelope and should be returned by November 15.

ROBERT E. PRESSWOOD,
Clerk to the Governors

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF ELECTRICAL ENGINEERING

Two Research Assistants required for a period not exceeding two years, one to work on the development of a new solid-state device, and one on the development of a new beam-scanning principle in echo-ranging. Degree in electrical engineering or physics is desirable. Salary up to £475 per annum.

Applications should be sent immediately to the Professor of Electrical Engineering, the University, Birmingham, 15.

EXPERIMENTAL OFFICERS AND ASSISTANT Experimental Officers in various Government Departments. The Civil Service Commissioners invite applications for pensionable posts. The posts are divided between following main groups and subjects (a) Mathematical and Physical Sciences, (b) Chemistry and Metallurgy, (c) Biological Sciences, (d) Engineering subjects and (e) Miscellaneous (including e.g., Geology, Library and Technical Information Services). Age limits: For Experimental Officers, at least 26 and under 31 on December 31, 1957; for Assistant Experimental Officers at least 18 and under 28 on December 31, 1957. Extension for regular service in H.M. Forces. Candidates aged 31 or over with specialized experience for Experimental Officer posts may be admitted. Candidates must have at least one of a number of specified qualifications. Examples are higher school certificate, general certificate of education, Scottish leaving certificate, Scottish universities preliminary examination, Northern Ireland senior certificate (all in appropriate subjects and at appropriate levels), higher national certificate, university degree. Candidates taking their examinations in 1957 may be admitted provisionally. Candidates without such qualifications may be admitted exceptionally on evidence of suitable experience. In general a higher standard of qualification will be looked for in the older candidates than in the younger ones. Salary (London): Experimental Officer, minimum £970 (women £894): Men's scale maximum £1,190. Assistant Experimental Officer. Starting pay £385 (at 18) up to £685 (women £661) at 26. Men's scale maximum £850. Women's scales are being raised to reach equality with men's by 1961. Somewhat lower outside London. Promotion prospects. Opportunities for further education.—Further particulars from Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting No. S94-95/57. Interview Boards arranged at intervals, as required. Early application is advised.

UNIVERSITY OF BIRMINGHAM

Applications are invited for a Senior Research Assistantship instituted for an investigation of the economics of coal cleaning. Applicants should have a good honours degree, preferably in physics, chemistry, chemical engineering, fuel technology or mining, together with research and/or industrial experience in some field of solid fuel preparation or utilization; a higher degree and a detailed knowledge of coal cleaning are desirable but not essential. It is expected that the investigation will take about three years. The successful candidate may, at some stage of the work, be required to visit solid fuel producing and consuming areas in Europe. Initial salary will depend upon qualifications and experience, but is likely to be about £850 a year for a well qualified man.

Applications, with name of two referees, should reach the Professor of Mining, the University, Edgbaston, Birmingham, 15, before November 7, 1957.

AUSTRALIAN NATIONAL UNIVERSITY

RESEARCH SCHOOL OF PHYSICAL SCIENCES

Applications are invited for the following posts in the Department of Geophysics: Senior Fellow; Research Fellow. One post will be for research on the experimental deformation of rocks and minerals, or for phase equilibrium studies at high temperatures and pressures. The other will be for seismology, involving chiefly the correlation of local tremors with geological structures and also crustal studies using large explosions. The salary for a Senior Fellow is determined within the limits £A 2,250 to £A.2,700, and appointment is made for an initial period of five years; thereafter the appointment may be made permanent. The salary for a Research Fellow is within the range £A.1,250 to £A.1,850, and appointment is for three years, with possible extension to the maximum of five years. Superannuation on the F.S.S.U. pattern will be provided and reasonable travel expenses will be paid.

Further details are available from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close on January 17, 1958.

AUSTRALIAN NATIONAL UNIVERSITY

RESEARCH SCHOOL OF PHYSICAL SCIENCES

Applications are invited for a Research Fellowship in the Department of Nuclear Physics. This Department, under Professor E. W. Titterton, has three accelerating machines in operation—600 KeV. and 1.25 MeV. Cockcroft-Walton accelerators and a 33 MeV. electron synchrotron. The main programmes of work involve light element and photodisintegration studies. The salary will be within the range of £A 1,250 to £A.1,850. The appointment will be for three years, with a probable extension to the maximum of five years. For an overseas appointee the appointment could be taken up at any convenient time during the year 1958. Superannuation on the Federated Superannuation System for Universities pattern will be provided and reasonable travel expenses will be paid.

Further particulars are available from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close on December 31, 1957.

UNIVERSITY OF MELBOURNE

AUSTRALIA

Applications are invited for a position of Senior Lecturer in Biochemistry. The salary range is £A.1,850 to £A.2,150 per annum. Initial salary will be determined according to qualifications and experience. Superannuation similar to F.S.S.U. in Great Britain will be provided.

Conditions of appointment may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close in Australia and London on December 31, 1957.

UNITED BIRMINGHAM HOSPITALS

THE GENERAL HOSPITAL
STEELHOUSE LANE, BIRMINGHAM, 4

Applications are invited for the appointment of an Assistant Biochemist (Basic Grade) at the General Hospital. Candidates should possess a science degree, preferably with honours in biochemistry or chemistry, or the A.R.I.C.

Applications, with the names of two referees, should be sent to the House Governor, within two weeks of the appearance of this advertisement.

DIFCO

PEPTONES AND HYDROLYSATES

for Microbiological Culture Media

Difco peptones and hydrolysates are prepared to meet the diversified nutritional and biochemical requirements of microorganisms. A single peptone cannot provide the essential nitrogenous nutriments for all cultural and metabolic processes. Difco peptones and hydrolysates have been developed to meet the various requirements for microbiological procedures including growth, preparation of toxin and vaccines, and for the study of microbial metabolism.

THE SECOND ARTIFICIAL EARTH SATELLITE

ON the morning of November 3, the U.S.S.R. announced from Moscow the launching of the second artificial Earth satellite—about a month after the launching, on October 4, of the first (*Nature*, October 12, p. 719).

According to preliminary reports from Moscow, the mass of this second satellite is about half a ton, that is, six times greater than the first. The total mass of the last-stage carrier-rocket and the satellite itself is estimated as being about one ton. The new satellite is now said to be travelling on an orbit inclined at about 65° to the equator, taking about 103 minutes to encircle the Earth at the rate of 17,840 miles per hour, and attaining a maximum height of about nine hundred miles. Whereas the first satellite (named by the Russians *Sputnik*) was launched in a north-east direction, the second satellite (*Novosputnik*) was launched towards the south-east.

First recordings of signals were obtained at 6 a.m. on November 3 at the Mullard Radio Astronomy Observatory, Cambridge, the 'bleep' signals being recorded on 20 Mc./s. and 40 Mc./s.; a hissing sound is also emanating from the satellite.

For the first time in history, a living mammal from the Earth is travelling in an Earth satellite, for the second one is carrying a dog: at the time of writing it was "calm and behaving normally" according to Russian reports. From apparatus connected with the animal, it is hoped to obtain data concerning respiration, heart-beat, blood-pressure and temperature, among other things. Additional apparatus installed in the satellite will signal data concerning cosmic rays and radiations from the Sun.

The launching of the second satellite is staggering in itself; but some Russian scientists have stated that it is hoped that the dog will return alive. They claim to have solved the immensely difficult 're-entry' problem; that is, safe passage through the atmosphere in spite of the great heat generated through friction. This possibility will be watched with the keenest interest. The greatest peril which the animal is facing is the absence, or considerable reduction in strength, of gravity; also it is conceivable that cosmic rays at that height may have a fatal effect on the nervous system.

One could express nothing but the greatest admiration for the work of the Russian scientists and technologists when they succeeded in launching the first satellite about five weeks ago. Indeed, valuable information is still being gleaned from this, which, contrary to the initial beliefs and statements of some men of science, is still travelling along its orbit (as also is its last-stage rocket carrier). This satellite has completed well-nigh 500 circuits. The orbit of the second satellite is claimed to be more satisfactory from the point of view of getting scientific results, and it is believed that it will have a longer life than the first. Moreover, according to Prof. B. Ukarkin, deputy chairman of the Astronomical Council of the Moscow Academy of Sciences, its signals will be more easily recorded and interpreted; the second satellite will also be more easily seen and for a longer time.

Last week (November 2) *Nature* was able to publish observations on the first satellite made by the staff of the Mullard Radio Observatory, Cambridge. In this issue, there follow articles from the staffs of the Royal Aircraft Establishment, Farnborough, and Jodrell Bank Experimental Station (University of Manchester), and other communications setting out still further valuable observations. Indeed, it is hoped that results obtained in other countries will be available for publication in due course.

There is no gainsaying the fact that scientists throughout the world are at present astonished at the weight of the second satellite. The technology involved, especially concerning the rocket propulsion needed to launch such a weight, challenges the imagination. Academician Dikushin is reported to have said that new sources of power were used. Moreover, it must be realized that not only have there been great advances in connexion with launching and getting the satellites on to their orbits, but also afterwards much scientific knowledge of prime importance is being, and will continue to be, obtained.

At the moment, however, and for the second time in about a month, *Nature* offers its congratulations to the U.S.S.R. on the prowess of its scientists and technologists as exemplified by the two satellites. It is curious that many people, including some scientists, attribute these great strides in scientific development to the presence in the U.S.S.R. of men of science who were either born or trained elsewhere, mainly in Western European countries. This is a positively dangerous conception, for, granted the activities of such men now in the U.S.S.R., the fact cannot be ignored that for a considerable time Russia's own men and women of science have contributed much to scientific advancement in many fields: and now, through these two satellites, the U.S.S.R. has presented the whole world with valuable new tools for making still further strides.

To what extent these satellites, and especially the rockets used for launching them, might be used as offensive war weapons is a matter of conjecture; but, as pointed out in *Nature* of October 12, this will become the responsibility of the politicians rather than of the scientists. In any event, whatever interpretation may now or later be placed on the aims and objectives of the Russian scientists in these great projects, the whole world of scientists must at present look on with nothing but admiration for the work of their colleagues in the U.S.S.R. Furthermore, there has been a tendency to be sceptical of Russian claims in the field of science. Yet no claim has so far been refuted; indeed, in view of these recent magnificent achievements, the Russians appear to have been rather modest.

INTERNATIONAL ADMINISTRATION

WHEN in July last the American Bar Association visited London, Mr. Herbert Brownell, the Attorney-General of the United States, made a deliberate appeal for a system of law for the nations of the world: this, he said, would be the greatest prize that lawyers could bring to a sorely troubled humanity. We have not yet applied our knowledge of how men may govern themselves by law to the determination of all disputes between countries, and what we need now is the development of the law of nations in order to bind the countries of the world with solemn voluntary pacts, in contrast to unilateral exploitation by the mighty. A civilization which had developed the Common Law and the Bill of Rights should not shrink from this new command of humanity, and the members of the American Bar looked forward to labouring with the English Bar in such a common effort.

It was at a subsequent Guildhall dinner given by the Law Society that Sir Winston Churchill, quoting Mr. Menzies, the Prime Minister of Australia, as saying that justice was not being achieved by the United Nations, made the appeal for changes in the United Nations for which he has been strongly criticized, particularly by those who continue to close their eyes to the contrast between the ideal and reality. Sir Winston did not suggest that Britain should leave the United Nations, but he did point to certain weaknesses in its foundations, and suggested that if the Assembly continued to take its decisions on grounds of enmity, opportunism or merely jealousy and petulance, the whole structure might be brought to nothing. Nor was his appeal for realism unhelpful in the face of Mr. Brownell's appeal. The main point of Sir Winston's speech was the warning against reliance upon any kind of paper agreements which his critics have ignored. "The mere creation of international organizations," said Sir Winston, "does not relieve us of our individual responsibility—at least not until the international systems are truly reliable and effective. It falls to the righteous man individually to do what he can and to form with his friends alliances that are manifestly concerned with justice and honour."

There is a sense, it is true, in which it is not the United Nations that is on trial but the member States which constitute that organization; but nevertheless Sir Winston is not alone in suggesting that, however essential it may be to have some such international organization, there is real danger that the United Nations as it is to-day may collapse. That was fully recognized in the debate in the House of Lords on July 25, and even last December Prof. Gilbert Murray, in writing of the shadow of barbarism that to-day lies over the whole civilized world, pointed to the weaknesses in the United Nations which flow from the presence of nations of widely varying standards of civilization and resources, but which nevertheless possess equal voting power. Prof. Murray said frankly that to continue moving in the present egalitarian direction and to refuse to admit that unequal things are indeed unequal is likely to endanger all that is best in Western civilization and to plunge the civilized world back into barbarism.

Prof. Murray was too consistent a champion of the League of Nations and of the United Nations for his realism to be distorted into an attack on international co-operation and the establishment of world law and order, and only political prejudice could so construe Sir Winston's realism. Moreover, Sir Ivone Kirkpatrick has also shown exactly how this egalitarian doctrine sets up unforeseen strains in the United Nations, weakens all sense of individual responsibility, and leads to the injustice and collective chaos to which Sir Winston and Mr. Menzies referred. Nevertheless, Sir Ivone, too, thought it would be wrong for Britain and other like-minded countries to leave the United Nations. They should rather use their influence to seek a return to the observance of its charter and in particular to the assumption by the Security Council and the General Assembly of the roles originally allotted to them.

To close one's eyes to inherent weaknesses and to regard as sacrosanct any paper agreement or particular organization, however impracticable amendment may be at any particular moment, does not help the task of establishing justice and the law of nations. Those weaknesses were particularly emphasized in the debate in the House of Lords, the motion of Earl De La Warr indeed asking the Government to open discussions with other nations at an early appropriate moment to remove these defects, while Lord Glyn's motion referred specifically to the misunderstanding of the respective functions of the Security Council and of the General Assembly. Any reform of the United Nations, it was recognized, is quite impracticable in the foreseeable future; but agreement was equally emphatic that we must seek to make the best possible use of it as it is.

Earl De La Warr made several valuable suggestions. First, he stressed the importance of a full understanding and complete unity between the United States and Britain. In this connexion he referred to the value of removing the misunderstanding of what is termed British colonialism. Next, he emphasized the danger of growth of group politics based on prejudice arising out of geographical, racial or colour considerations. Nothing is so likely to weaken, if not actually destroy, the influence of the United Nations. He laid some stress also on a high standard of representation at the United Nations, on the importance of an international police force, and on the existence of a firm system of law and order, effectively enforced, as a precondition of nations relinquishing the right of self-defence.

Lord De La Warr held that the United Nations is indeed on trial to-day, and that it is in many ways an ineffective body. Nevertheless, what the United Nations can do, and can do now, needs to be emphasized, so that it may grow into a body which can ultimately free mankind from the fear of war, and from the type of international behaviour that has so often led to war. In the debate which followed, no one challenged his statement that there are in practice two standards operating in the United Nations: one for the law-abiding nations and another for the law-breakers. Lord Glyn, commenting on the multiplicity of international organizations which normally work closely with the United Nations, seemed to question the need for so many specialized agencies, and to suggest that they might be combined in some manner to strengthen that body and make it more effective. Lord Boyd Orr suggested that, by promoting co-operation between specialized agencies such as the Food and Agriculture Organization and the World Health Organization in the attack on limited practical objectives in human welfare, the United Nations might bring about a better atmosphere in the world and a clearer understanding of the difficulties of different nations. Underlying the whole debate was the recognition that international law can exist only if there is the will to obey the law; and, as Lord Winster said bluntly, it is not respect for law but political and economic considerations that prevail. Even Lord Silkin, in the most optimistic speech of the debate, recognized that the United Nations could not be more than the sum of its members. Thus the debate contributed to a somewhat clearer understanding of the relative strength and weakness of the United Nations, and it also brought out, as Lord Attlee mentioned, its dependence on public opinion.

It is as a contribution to that end that two recent books, both of which draw some comparison between the League of Nations and the United Nations, are valuable. In the first of these*, Bernard Moore, giving a lively account of his seven years at the United Nations, shows how the decision to locate the headquarters of the Organization in New York opened the door to some of the lobbying and irresponsibility on which Sir Ivone Kirkpatrick also commented. Mr. Moore obviously believes that the drawbacks far outweigh the advantages of placing the Organization in New York. He brings out both the great importance of the Secretariat and the strain which is imposed on many of its members at Lake Success. But the great value of his book lies in the way he brings to life the human issues in the functioning of such an organization and the importance of the time factor on the larger scale. He, too, emphasizes the importance of more than idealism: goodwill cannot be taken for granted; nations, governments and statesmen need to learn a new technique, to develop a new understanding and to discard old, deeply entrenched habits and ideas.

Mr. Moore's book will show the general reader just why the United Nations needs time to grow. Mr. Loveday's "Reflexions on International Administration"* are concerned with the development of the new technique, and with the factors which determine the morale and efficiency of an international organization. It is not a book for the general public, though it contains much to interest both scientist and technologist. On the major issues that in the past few years have brought the future of the United Nations into question it bears indirectly, though, like Mr. Moore, Mr. Loveday, drawing on his twenty-five years experience as an international official, shows how much an efficient administration can contribute to the prevention of misunderstandings and the establishment of confidence.

Like Mr. Moore, too, Mr. Loveday recognizes that, in spite of a marked tendency at the outset to discount the experience of the League, the United Nations in fact owes much to its predecessor, though he points out that principles and methods of administration which had proved their worth prior to 1939 are not necessarily valid to-day. The change in the political climate alone would be responsible. What used to be considered technical questions outside the political field may now be subject to power or voting-power politics, and governments are increasingly unwilling to seek an objective study of the problems they have to solve. The best solution is rarely sought, only the easiest compromise; and Mr. Loveday says frankly that the effectiveness of almost all the organs of the United Nations has suffered. Agreement has not been reached because it has not been sought.

It is in what are almost asides that Mr. Loveday illumines the issues debated in the House of Lords, as when discussing staff rules and regulations and the need in any international organization for a body which can discuss administrative problems at the political level. He refers to the danger, in its absence, that the Secretary-General will be unduly exposed both to external pressure to act according to the wishes of individual governments and to unavoidable (or unnecessary) criticism. Certain questions in this context, he admits, are best ventilated in public, "But the vast majority of questions affecting the personnel and a large proportion of diplomatic issues are best settled behind closed doors". Again, he notes the desirability of relieving the General Assembly of unnecessary detail so that it can concentrate on major issues. His suggestion for easing the problem of recruitment could in itself contribute to the improvement of international understanding and the whole atmosphere of co-operation. As the best means for recruiting nationals from the less-advanced countries, he suggests financing educational facilities at certain universities on a large scale. To succeed, an all-round education and normal Western European educational standards and very liberal financial support would be necessary, for only the outstanding graduates from these university centres should stand a chance of selection. There must be a large group from which to select, and the education given must be of real value to those graduates who are not recruited and return home.

* The Second Lesson: Seven Years at the United Nations. By Bernard Moore. Pp. ix+220+8 plates. (London: Macmillan and Co., Ltd., 1957.) 21s. net.

* Reflexions on International Administration. By A. Loveday. Pp. xxi+334. (Oxford: Clarendon Press; London: Oxford University Press, 1956.) 42s. net.

The implications of any such scheme are far-reaching and, however it might be financed, its organization would require the help of an independent international body such as the International Association of Universities or the International Association of University Professors and Lecturers. The suggestion is one that merits the attention both of the Technical Assistance Board and of Unesco, though Mr. Loveday adds that it might be more practical, in the first place, to attempt to create a European rather than a world Civil Service and for this purpose possibly a common machinery for recruitment. Another important observation is in regard to the Trusteeship Council. The failure of that body, which Mr. Loveday contrasts unfavourably with the Permanent Mandates Commission, to win a respect proportionate to the importance of its functions is attributed partly to its practice of allowing substitutes. It is no more proper, he remarks, for a body the composition of which changes to pass judgment on the manner in which a third party has carried out its obligations than it would be for a jury with changing composition to record a verdict.

These citations can but illustrate the quality of Mr. Loveday's book, and the way it stimulates the clear thinking and honesty of purpose that are two essential steps towards improving the effectiveness of the United Nations. They are, of course, incidental to his main theme, which is discussed in two parts, the first dealing with personnel policy and the second with the operation of the administration. In the first, which discusses sympathetically and with insight and common sense the characteristics and special features of the life of an international official, the qualities required, the maintenance of morale and the problem of recruitment as already noted; the chapters on recruitment and maintenance of morale emphasize several points of great interest in connexion with technical assistance and the recruitment of professional men for overseas work. Mr. Loveday, for example, directs attention to the importance in international administration of constructive imagination, to the implications of the tendency almost throughout the world for higher education to degenerate into technical training, to the relative importance of being able to offer a career as such, as distinct from an officer's professional career; much that he observes in regard to grading and promotion also has a bearing on professional employment generally.

In the second part of the book Mr. Loveday has some comments on advisory committees and on councils and boards, particularly on the place of the scientific or technical expert, which do not always run with the views expressed by Prof. K. C. Wheare in his "Government by Committee". It is these chapters and that on research which the professional man, whether scientist or not, will find of most interest, for there is also much in this part to interest the manager or administrator in general. Mr. Loveday's shrewd common sense rarely fails to stimulate thought about related issues in industrial, national or international administration, and if the dangers he notes are to be eliminated much help will be required from professional organizations. The danger of selecting directors on account of their technical reputation alone, of preferring a man with a world reputation for his contribution to some branch of knowledge to a less well-known but younger man who possesses to a greater degree the indispensable qualities of leadership, creative imagination and willingness to co-operate with others, are not easily avoided without such professional assistance and goodwill.

On the question of research, apart from noting the reluctance of governments to appoint independent experts able to view controversial matters in a spirit of scientific detachment, Mr. Loveday is averse to the multiplication of institutions at the international level. He recognizes that in the social sciences an international secretariat may, in a limited field, be more competent. Such institutions can and should conduct a type of research for which universities are ill equipped; but, in general, universities are better able to provide the type of competence required. In the natural and applied sciences it is still more exceptional for the establishment of an international laboratory to offer any advantage over the use of an existing institution. The slightest acquaintanceship with the activities of the Nuffield or Rockefeller Foundations should confirm the soundness of this view, and indicate how the organization of research in this way could contribute slowly but surely to international understanding and goodwill.

Mr. Loveday indicates ways in which the United Nations could be enabled to function more effectively and the risk of misunderstandings and internal tension reduced. He makes no large claims that the objectives of its charter will be approached other than gradually in course of time by a long process of co-operative effort. His book, with its clear statements of the conditions in which an international secretariat can function efficiently, none the less indicates small ways in which the individual can sometimes assist to that end. It should contribute to that honesty of purpose, realism and clear thinking for which Sir Winston Churchill, like Prof. Gilbert Murray, appealed, and which must reinforce our idealism if the United Nations is ever to fulfil the hopes in which it was founded. Written before the Suez crisis, it leaves no room for doubt that, if the United Nations is not to collapse, its member States must recollect that the existence of an international organization presupposes the acceptance and observance of certain common standards: the urgent need is not for amendment of its charter but for a new and constructive approach to the whole purpose and function of the United Nations Organization and its agencies.

MAGNETOHYDRODYNAMICS

Magnetohydrodynamics

By T. G. Cowling. (Interscience Tracts on Physics and Astronomy, No. 4.) Pp. viii+115. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1957.) Paper, 1.75 dollars; hard cover, 3.50 dollars.

AFTER a protracted infancy, the field of magnetohydrodynamics has rather suddenly entered into what might be called its adolescence. This is largely due to the tremendous extension of observational material, both geophysical and astrophysical, that has become available during the past ten years or so. Apace with this has gone the development of certain theoretical ideas such as the notion that the terrestrial, solar, and stellar magnetic fields are due to some sort of self-amplifying dynamo mechanism.

This short tract represents the first coherent survey of the subject to appear in the literature. Prof. Cowling has been more intimately associated with all the phases of growth of magnetohydrodynamics than any other man, and we owe him a debt of gratitude for the present work. Such an effort is readily exposed to facile criticism by those who come after the pioneers and receive their material already predigested. The book shows the vestiges of pioneering; but the framework laid down here for the first time will no doubt remain and will stimulate others to fill in further details.

The treatment is essentially theoretical, observations being invoked only when they have a bearing on the theory presented. This greatly helps to make the presentation consistent in so brief a compass. The author wisely confines himself in the main to those aspects of the subject that can be described in terms of the field equations of classical physics. These are a combination of Maxwell's equations with the Euler equations of fluid motion, suitable coupling terms being inserted in both. The first chapter is devoted to establishing these equations and to a discussion of their general content. The presentation is very lucid; but one would wish it much longer, perhaps at the expense of some of the later, admittedly rather speculative, models of solar magnetic fields. The next three chapters deal with magnetohydrostatics, hydromagnetic wave motion, and the effect of a magnetic field on stability; that is, on the onset of turbulence as well as of thermal convection. There are a number of examples from solar physics. Some of the recent laboratory experiments and pertinent theories on the flow of liquid metals in a magnetic field are rather well covered.

The next chapter deals with dynamo theories of the Earth's field and gives a brief account of the effect of turbulence on magnetic diffusion. The last, brief chapter outlines the theory of some of the remarkable phenomena met with in rarefied ionized gases and gives applications to interstellar gas clouds. One of the outstanding features of the book is the gratifyingly close connexion which is drawn between the laboratory experiments with liquid metals and the analogous problems of stability in astrophysics.

The equations of magnetohydrodynamics are, in a manner of speaking, the most non-linear of all the known equations of mathematical physics. Hence such surprising phenomena as the presence of cosmic magnetic fields wherever there are conducting liquids. This is something that could not have been predicted speculatively by any stretch of the imagination. Given our mathematical inadequacy in the face of non-linear equations, it will be a very long time before we can hope to possess rigorously deductive arguments for any essentially non-linear problem, for example, the dynamo problem. In the meantime we must be content with intuitively plausible but grossly over-simplified models. The situation is here similar to the physics of turbulence, which has not yet yielded to a deductive treatment in spite of long-continued efforts. The reader should keep this in mind when perusing Prof. Cowling's sometimes deceptively elegant discussion of the non-linear phenomena.

The book is, of course, essential for astrophysicists and geomagneticians. In addition, it should be valuable as a concise introduction to the subject for those now numerous physicists who are concerned with magnetohydrodynamics in the study of gas discharges.

WALTER M. ELSASSER

ZOOLOGICAL LITERATURE, 1954

The Zoological Record, Vol. 91

Being the Records of Zoological Literature relating chiefly to the year 1954. Edited by G. Burder Stratton. Pp. vi+2010. (London: Zoological Society of London, 1957.) £6.

THE issue of the present volume within little more than two years of the literature to which it refers is a remarkable achievement and reflects great credit on all those concerned in the compilation of this invaluable publication. Once again there is an increase on the previous volume in the number of zoological publications, an extra 260 pages, but from this must be deducted Vermes (1952), unavoidably omitted from Vol. 89. This indicates a rise of about 5 per cent in the period under consideration as compared with 10 per cent in the previous year.

The relative size of the various sections shows little variation from year to year, and although it bears some relation to the number of species in each group it is evident that some types of animals attract much more attention than others, especially those of economic interest. As would be expected, Insecta with 546 pages, involving 4,060 titles, is by far the largest section, followed by Vermes—another very large group. The space occupied by each of the other sections is arranged in descending order as follows: Mammalia, Protozoa, Arachnida, Mollusca, Aves, Pisces, Trilobita, Crustacea, Reptilia, Amphibia, Coelenterata, Brachiopoda, Comprehensive Zoology, Echinoderma, Bryozoa, Protochordata, and Porifera.

The number of pages, however, does not necessarily indicate the number of titles, and in the present volume the consecutive number which preceded each reference has been omitted in some of the sections. Judging from the number of titles, Aves, with a total of 1,972, is still the most popular group after Insecta, although its 1,972 titles and their analysis occupies fewer pages than Mammalia with 1,796 titles. It is curious that such a comparatively small group as the Amphibia, of little economic importance, should have more than three times as many references as such a large and comprehensive group as Echinoderma, but in zoology, like other subjects, fashion must be taken into account. There is no indication of any diminution in the amount of taxonomic work, for the present volume records a total of 2,418 new generic and subgeneric names during 1954, a 50 per cent increase on the previous year.

The compilation of the "Zoological Record" is a heavy task, and requires considerable financial assistance to produce it at any reasonable cost. The list of donors includes institutions and individual subscribers in many parts of the world, the two leading contributors being the Royal Society and Unesco, but further donations will be required if the price of this invaluable publication is to be kept within reach of private individuals. EDWARD HINDLE

USEFUL FUNGI

The Friendly Fungi

A New Approach to the Eelworm Problem. By C. L. Duddington. Pp. 188+24 plates. (London: Faber and Faber, Ltd., 1957.) 21*s*. net.

ALTHOUGH, as the author states, this is not a technical book, it nevertheless embodies a wealth of authoritative information on predacious fungi which has hitherto been available only as fragmentary data dispersed among various British and foreign scientific journals. It deals with an absorbing subject which is made all the more interesting by the engaging and informal style of the text. Indeed, much of the merit of the volume is derived from the author's vivid and sometimes dramatic narrative surrounding the warring factions in Nature and their harnessing for useful purposes.

As the sub-title indicates, the book deals with the part played by aggressive soil-inhabiting fungi in checking the ravages of plant-parasitic eelworms which are to-day acknowledged to be among the farmer's worst enemies. It examines the possibility of further stimulating this biological control by inoculating the soil with potent strains of selected fungus cultures and by treating the soil to foster increased prolificity and activity of the predators. To achieve such a disturbance of the state of dynamic equilibrium in favour of the fungi is by no means simple, and it is to the author's credit that it is his own work in this field which has provided the most useful pointers to surmounting some of the inherent difficulties.

The most fascinating section of the book is that devoted to the remarkable eelworm-trapping mechanisms of predacious fungi—the sticky hyphal networks, the sticky knobs, the constricting rings and the passive ring traps. Equally exciting is the account of the laboratory techniques which have been devised for studying these mechanisms—the employment of a pneumatic micromanipulator for handling the microscopic organisms and the use of cinematograph film for recording their movements. All is presented in a manner which is readily understandable to readers with no special scientific knowledge.

A notable feature of the book is the excellent and impartial way in which the author has summarized and evaluated research work conducted on predacious fungi in other countries; for example, the investigations into the control of root knot eelworm on pineapples in Hawaii and the attempted control of both plant and animal nematode parasites in France. Unfortunately, the results from field experiments carried out in England on the control of potato root eelworm and cereal root eelworm are less convincing since they are expressed mainly in terms of crop yield. The logical criterion for measuring the nematicidal effects of the different treatments would be the comparative figures for larval or cyst populations of the eelworms in the soil recorded prior to treatment and after cropping. The reviewer has the impression that certain suppositions have been developed which merely reflect the effects of cultural or manurial treatments in enhancing the growth of the crop rather than in suppressing the eelworms.

The book is well illustrated with excellent photographs and carefully executed line-drawings, is provided with a useful bibliography and is free from major errors. On p. 17, Northern Ireland is mistakenly cited in a context appropriate to the Republic of Ireland, and some half-dozen misspellings of scientific names are evidently attributable to typographical errors. R. CHAMBERLAIN

A RECONSIDERATION OF AFFECT

Pain and Pleasure

A Study of Bodily Feelings. By Thomas S. Szasz. Pp. xvi+301. (London: Tavistock Publications, Ltd., 1957.) 30*s*. net.

IT is, perhaps, a wise thing for scientists as well as artists to stand back occasionally and see what their work looks like at a distance. In this book the author is doing this with basic psychological terms and their application to psychoanalysis. Dr. Szasz is professor in the Department of Psychiatry at the State University of New York College of Medicine and, since he is an honours graduate in physics as well as medically qualified and trained in psychoanalysis, he has written the scholarly book one would expect.

The first part is a consideration of the philosophical aspects of the subject, and the second, third and fourth are devoted to various theories of pain, bodily feelings and pleasure. He accepts Russell's views regarding the separation of the material of physics into 'public data' and that of psychology into 'private data', and wisely refuses to accept explanations which try to combine the two. He presses for pain and pleasure to be classed as affects, as Fenichel suggested. Pain, he considers, is associated with the idea of something being taken away, or the threat of such loss or injury. Pleasure, on the contrary, is evoked by something being given to us even if it is only sensory stimulation or its discharge. He applies these views to such conditions as hypochondriasis, pseudocyesis, hysterical anæsthesia, and particularly to the phantom limbs which are so commonly felt after amputation and the curious pains felt in them.

This is not a book to read when one is half-asleep over a fire; it needs the reader's close attention. Nevertheless, everyone who writes on pain and pleasure will have to take the writer's ideas into consideration, and their application may be of considerable value.

There are an excellent bibliography, covering four pages, and a good index. The paper is good and the printing clear. CLIFFORD ALLEN

OBSERVATIONS ON THE ORBIT OF THE FIRST RUSSIAN EARTH SATELLITE

By STAFF OF THE ROYAL AIRCRAFT ESTABLISHMENT, FARNBOROUGH

THE launching of the first Earth satellite has evoked widespread interest, and the regular appearance over Great Britain of the 'Sputnik', advertised by its radio transmitter, has been followed closely by many observers at various centres.

At the Royal Aircraft Establishment a series of radio observations has been made, extending over most of the period of three weeks during which the satellite's transmitter was functioning. Both interferometer and Doppler records have been obtained, and a considerable amount of data is now available for analysis. Up to the present, our attention has been focused on estimating the orbit constants, but it is expected that further study will yield valuable information on radio propagation phenomena.

Interferometer Measurements

On October 5 it was decided that sufficient apparatus was available to build an interferometer on 40 Mc./s. Four aerials were erected at Lasham, one pair lying approximately north–south (335°), and the other pair accurately at right angles, the spacing of each pair being 100 ft.—about four wave-lengths. Each aerial consists of a bent $\lambda/2$ dipole (90° at the apex) at a height of $\lambda/4$ above ground, and all four are orientated in the same direction; this system gives good all-round cover with some vertical directivity—on some nights eight transits of the satellite were recorded.

The north–south aerials are interconnected by a concentric feeder, with a $3\lambda/8$ artificial line, having the same characteristic impedance as the cable, interposed at its centre. This arrangement gives an infinite standing-wave-ratio pattern in the feeder, the phase depending only on the phase difference between the e.m.f.'s in the aerials. A four-phase crystal switch in the artificial line transfers the pattern to the high-frequency receiver, and the detected output is applied to a pair of phase-sensitive rectifiers which are switched by the crystal voltages. An identical system is used for the east–west aerials. Phase measurement from the aerials onwards is accomplished with a standard deviation of 3°, corresponding to a directional accuracy of 0·1°.

A typical record taken at Lasham is shown in Fig. 1. The 1-sec. timing-pulses are related to G.M.T. with an accuracy of milliseconds, so that the time at any point on the record may be read to within one-tenth of a second. The remaining traces give the sine or cosine of the phase difference at a pair of aerials: reading from top to bottom, the record shows the north–south sine, the east–west cosine, the time and the east–west sine.

The received signal strength fluctuates, so that the tracking information lies in the successive times at which the traces cross the zero-levels, corresponding to successive phase changes of 180°. With an aerial spacing of 100 ft., each such change indicates an increment of 0·123 in the direction cosine of the satellite position vector, referred to an axis passing through the phase centres of the two aerials; apart from an uncertain additive constant, therefore, the records permit plotting two direction cosines against time, the north–south at increments of 0·123 and east–west at increments of 0·0615.

Preliminary estimates of the satellite's height and track were obtained by assuming a constant speed (v) along a straight line at constant height (h).

If l_1, l_2, l_3 denote the direction cosines of the satellite position vector ρ with respect to the east, north and vertical axes at the interferometer, the east–west component of the satellite's velocity is given by :

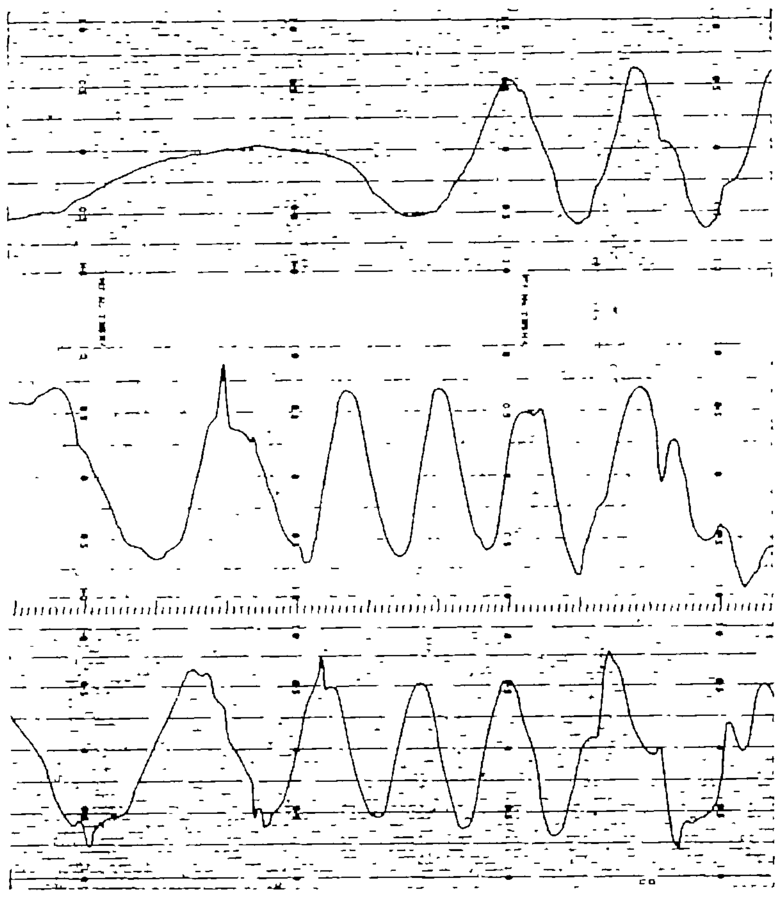

Fig. 1. Section of record from Lasham interferometer at 21.10 hr Monday, October 14, 1957

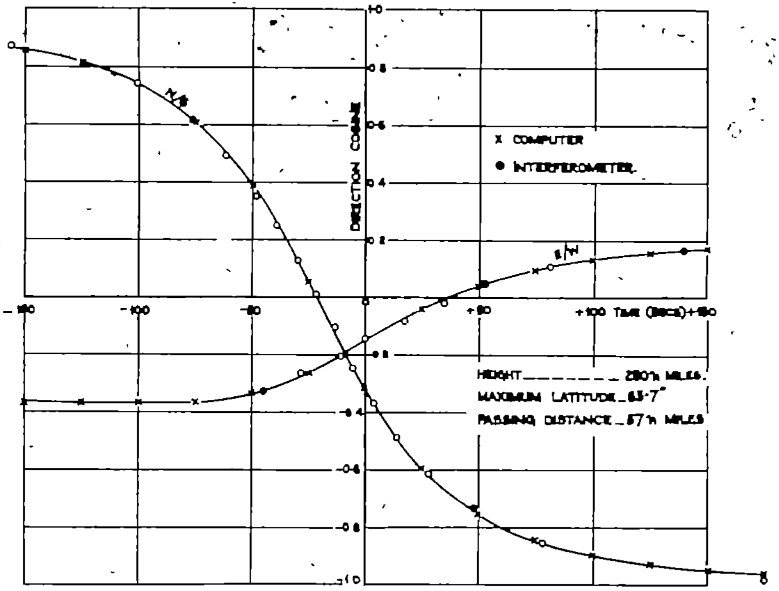

Fig. 2. Digital computer results compared with the interferometer observations for the transit at October 13, 05 min. 30 sec.

$$\frac{d}{dt}(\rho l_1) = \frac{d}{dt}\left(\frac{hl_1}{l_3}\right), \text{ since } \rho l_3 = h$$

A graph of l_1/l_3 against time should therefore yield a straight line, since v is assumed to be constant. The zero levels of the observed direction cosines are adjusted until a straight line is obtained; the gradient is then the east–west velocity component divided by the height. A similar relation holds for the north–south component, so that taken together the two gradients determine the height and the bearing of the track, since the satellite's speed is a known function of height and orbital time for any assumed orbit.

The passing distance (that is, horizontal range to the point below nearest approach) can now be derived, and, since the bearing of the satellite at any time is determined by the ratio l_1/l_2, the time of latitude transit can also be found. This time appears preferable to the more usual meridian transit, because the satellite performs an integral number of complete orbits between latitude transits.

In order to calibrate the interferometer system, an aircraft was flown over the site on October 15, in directions corresponding to the satellite's track and with a similar speed/height ratio. On each of three flights, the value of v/h deduced from the interferometer records by the above method was within 2 per cent. of the value given by independent fixes.

Table 1. MORNING TRANSITS

Date October	Nominal time	Height (n. miles)	Track bearing (degrees true)	Time of transit latitude 51° 10½′ N.		
				hr.	min	sec
11	5 30	265	135	05	32	15
12	5 30	228	138		—	
13	5·30	252	140	05	30	16
14	5 30	253	140	05	29	22

Table 2 EVENING TRANSITS

Date October	Nominal time	Height (n. miles)	Track bearing (degrees true)	Time of transit latitude 51° 10½′ N		
				hr	min.	sec
10	23 00	136	038		—	
14	21 00	138	034	21	11	20
15	21·00	133	034	21	08	43
16	21·00	124	040	21	05	25
24	18·30	123	039	18	41	30

Results for a number of morning and evening transits are given in Tables 1 and 2.

Since the rotation of the orbit in the orbital plane is very slow (see below), the figures quoted can be regarded as independent estimates of the constant height and bearing at the morning and evening transits respectively. The average height for the morning transits is 250 n. miles, with a standard deviation of 13 n. miles; and for the evening transits 130 n. miles, with a standard deviation of 6 n. miles.

Although fair accuracy can be achieved rather quickly by the method described, it becomes laborious to extract the full accuracy which (it is believed) the quality of the data warrants. Also, the analysis is valid only for near transits, because of the assumptions made. To remove this restriction, and to improve the accuracy of fitting, we have prepared a preliminary programme for a Pegasus digital computer, taking account of the Earth's curvature and rotation, and assuming that the observed portion of the orbit is circular. Trial values of height, bearing and passing distance are inserted, and the computer calculates a succession of values for the two direction cosines measured by the interferometer. These values are compared with those obtained from the records, and the input parameters adjusted until the two sets agree: a typical result is shown in Fig. 2. The digital computer results for each of the four morning transits of Table 1 give a height of 250 n. miles, with an uncertainty of no more than ± 5 n. miles.

Even with a digital computer the method is still rather laborious; as a further development we intend to make the computer do the curve fitting, using the

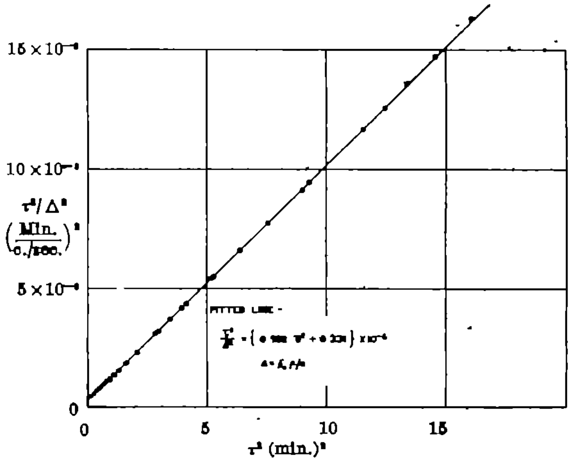

Fig. 3. Least squares fit to Banbury Doppler data for October 15, 21 hr. 08 min. 44 sec

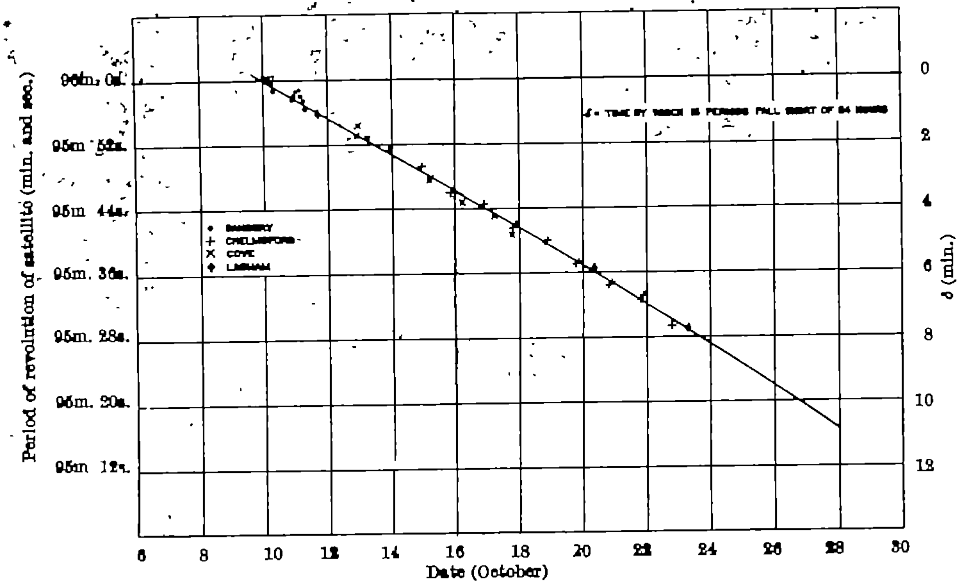

Fig. 4. Orbital periods derived from Doppler and interferometer data

method of differential correction described in ref. 2, p. 309.

Doppler Measurements

Within the Ministry of Supply, Doppler measurements have been made at the Royal Aircraft Establishment (Aberporth, Bramshot and Cove) and at the Royal Radar Establishment, Malvern. Results have also been received from the Post Office Radio Stations at Baldock, Banbury and Brentwood, from the Tatsfield receiving station of the B.B.C. and from the Great Baddow Research Laboratories of Marconi's Wireless Telegraph Co., Limited.

The reduction of the measurements at a single station begins with the determination of t_0, the time of closest approach; this also determines f_0, the frequency of the satellite transmitter. The observed frequencies f can then be reduced to a table of $\dot{\rho}$ against τ, where $\dot{\rho} = c(f - f_0)/f_0$, ρ being the Doppler station-satellite distance and τ the time measured from the instant of closest approach.

Ignoring the curvature of the orbit and of the Earth, we have:

$$\rho^2 = \rho_0^2 + V_R^2\,\tau^2$$

V_R being the relative velocity between the satellite and the observing station, and ρ_0 the minimum distance. The equation is equivalent to

$$\frac{\tau^2}{\dot{\rho}^2} = \frac{\rho_0^2}{V_R^4} + \frac{\tau^2}{V_R^2}$$

so that a graph of $\tau^2/\dot{\rho}^2$ against τ^2 should be a straight line, from which V_R and ρ_0 can be estimated. This is shown in Fig. 3, which is for the transit at 21.08 on October 15, observed from Banbury.

V_R, ρ_0 and t_0 represent the maximum information that can be obtained from one transit over one station. To locate the orbit it is necessary to combine observations from several stations on the same transit; the alternative of observing successive transits at one station has not been used, since the effective base-length (700 n. miles) is much greater than the height.

The transit at 21.08 on October 15 passed very close to Great Baddow, and it was observed from Aberporth, Malvern, Banbury, Bramshot and Great Baddow. From the V_R and ρ_0 estimates given by these stations, the satellite's height and track can be estimated, taking into account the curvature of the orbit and the curvature and rotation of the Earth. The data being redundant, a least squares fit can be obtained; the height of this evening transit was found to be 124 n. miles, with a standard deviation of 5 n. miles.

As with the interferometer data, it is hoped to programme these calculations for a digital computer, in order to obtain accurate results more quickly.

General Features of Satellite Orbits

For near satellites, within, say, 1,000 miles of the Earth's surface, the main perturbations to the basic elliptic orbit result from the Earth's oblateness and the atmosphere: by comparison, the influence of the Sun and Moon, and relativity effects, can be safely ignored.

The perturbations due to oblateness have been evaluated theoretically in a recent study[1] for orbits of small eccentricity (about 0·05 or less). The orbital plane is found to rotate about the Earth's axis in the direction opposite to the motion of the satellite, at a mean rate of $10\cdot00\,(R/\bar{r})^{3\cdot5}\cos\alpha$ degrees per day, where R is the Earth's equatorial radius, $\bar{r}$ the harmonic mean distance of the satellite from the Earth's centre, and α the (constant) inclination of the plane to the equator. The radial distance r of the satellite from the Earth's centre also departs from the value appropriate to a simple ellipse; r oscillates twice during each revolution with an amplitude $0\cdot94\,(R/\bar{r})\sin^2\alpha$ nautical miles, and three times during each revolution with an amplitude $0\cdot06\,(R/\bar{r})^2\sin^2\alpha$ nautical miles. It is also found that the major axis of the ellipse rotates in the orbital plane at a rate of $5\cdot00(R/\bar{r})^{3\cdot5}(5\cos^2\alpha - 1)$ degrees per day. This rotation is in the same direction as the satellite's motion if α is less than 63·4°, and in the opposite direction if α is greater than 63·4°. Finally, the period of revolution of the satellite, from one northward crossing of the equator to the next, is $14\cdot5\sqrt{(R/\bar{r})}.\sin^2\alpha$ seconds greater for an inclined orbit than for an equatorial one.

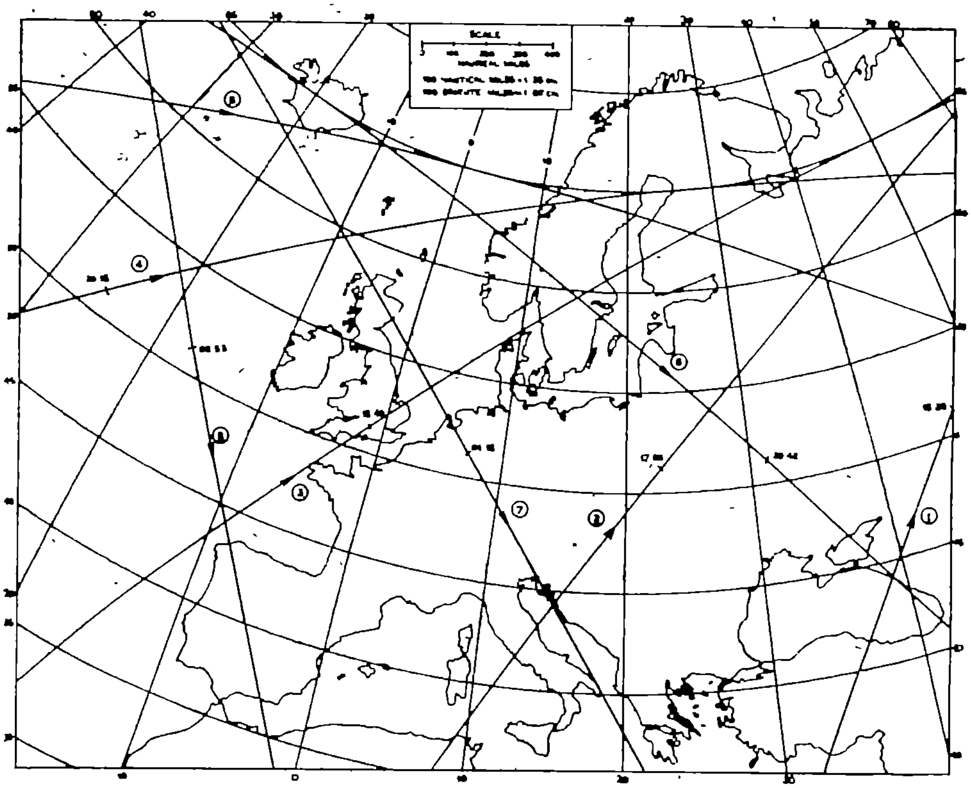

Fig. 5. Estimated track of the Russian Earth satellite for night October 24–25. Numbers indicate times in G.M.T. The first revolution is shown by (1), the second by (2), and so on Between latitudes 30° and 55° the satellite covers about 3° of latitude per min.

For October 25–26 subtract 9 min. from the times and move track 1·6° to the west
,, ,, 26–27 ,, 19 ,, ,, ,, ,, ,, ,, ,, 3·4° ,, ,, ,,
,, ,, 27–28 ,, 30 ,, ,, ,, ,, ,, ,, ,, 4·8° ,, ,, ,,
,, ,, 28–29 ,, 42 ,, ,, ,, ,, ,, ,, ,, 6·1° ,, ,, ,,
,, ,, 29–30 ,, 55 ,, ,, ,, ,, ,, ,, ,, 7·1° ,, ,, ,,

The main effect of the atmosphere is to reduce the length of the major axis, making the orbit more nearly circular. This is because most of the retardation due to drag occurs near perigee; consequently, there is a loss of altitude at the subsequent apogee. The reduction in the length of the major axis shortens the orbital period, and it is possible to estimate the air density from the observed rate of decrease of the period.

Orbit of the First Russian Earth Satellite

Orbital calculations for the first Russian Earth satellite have been made much easier by the fact that α is near 65°. This means, according to theory[1], that the rate of rotation of the major axis is not more than 0·4 deg. per day in the direction opposite to the satellite's motion, whereas for a near-equatorial orbit the corresponding figure would be as much as 14 deg. per day. Because this rotation is so slow, the height of the satellite as it crosses any latitude going north, say, should be almost the same on successive days. This conclusion is confirmed by the heights so far measured; but since the estimates of height are subject to some inaccuracy, it is not yet possible to obtain a reliable observed value for the rate of rotation, to compare with theory.

For the same reason, the small perturbations in radial distance, of order 1 mile, cannot be detected, so that an elliptical orbit has been assumed:

$$\frac{1}{r} = \frac{1}{\bar{r}}\,(1 + e\cos\varphi)$$

where e is the eccentricity and φ the angular travel in the orbital plane. The difference between the two values of φ on northward and southward crossings of any latitude is known: it is 61·4° for latitude 51·2° N. if $\alpha = 65°$. If $\bar{r}$ is known, two measurements of height suffice to determine e and the absolute values of φ. The required value of $\bar{r}$ can be found from the orbital period, which has been measured with good accuracy.

Values of orbital period given by the measurements from the Doppler stations at Banbury, Great Baddow, and Cove, and the interferometer at Lasham, are plotted in Fig. 4. It is seen that the period decreased from 96 min. on October 10 to 95 min. 30 sec. on October 23, and that the rate of change is slowly increasing. The right-hand scale in Fig. 4 shows the value of δ, the time in minutes by which 15 revolutions fall short of 24 hr. This is a convenient parameter for the first Russian Earth satellite, because δ is small and δ^2 can often be ignored. The mean distance $\bar{r}$ can be expressed as $\bar{r} = 3737\cdot7\,(1-\delta/2160)$ nautical miles. When this expression for $\bar{r}$ is used, the rate of rotation of the orbital plane, $10\cdot00\,(R/\bar{r})^{3\cdot5}\cos\alpha$, may be written as $3\cdot167\,(1+\delta/617)$ deg. per day in the direction opposite to the satellite's motion. In obtaining this figure, α has been kept at the round number value of 65°, though it is probably a small fraction of a degree lower. Since the Earth turns through 360·986 deg. in a (solar) day, it follows that the $(n+15)$th orbit is west of the nth orbit by

$$4{\cdot}153-0{\cdot}24783 \text{ deg.} \qquad \text{(i)}$$

These crossings are about 24 hr. apart, the $(n+15)$th being 3 min. earlier than the nth, but on the next day. It also follows, adding 360° to (i) and dividing by 15, that the $(n+1)$th orbit is west of the nth by 24·277 − 0·01653 deg. With this information, and one 'fix' on the track, it is possible to plot the track of the satellite over the Earth's surface for several days, using linear extrapolation at future dates from Fig. 4. This process has been carried out regularly since the satellite was launched, and maps, of which Fig. 5 is typical, were distributed to the various tracking stations. The shift in the track between October 11 and October 25, as predicted by this method, was found to be within 1 per cent of the observed value. Thus the theoretical value for the rate of rotation of the orbital plane is confirmed.

Finally, there is the effect of the atmosphere to be considered. Since the orbital period T varies as (major axis)$^{3/2}$, a 1 per cent change in T corresponds to a 2/3 per cent change in the major axis. The change in T thus gives the change in the major axis immediately. The air density has been evaluated roughly, on the assumption that the change in major axis is due to a reduction in apogee only, arising from an impulsive change in satellite velocity at perigee. This change in velocity is then compared with the integrated effect of the drag/mass ratio, assuming some particular atmospheric model. The factor of difference between the two values for the change in velocity gives an indication of the factor by which the density in the assumed model is in error. At the satellite altitude, free-molecular flow prevails, and, since the isothermal Mach number of the satellite is high, the drag coefficient is taken as 2. This very approximate method gives the density at 130 n. miles altitude as about 2×10^{-10} of that at sea-level.

Details of the estimated orbit for noon G.M.T. on October 15 are as follow:

Height going north at latitude 51·2° N.	130 ± 6 n. miles
Height going south at latitude 51·2° N.	250 ± 5 n. miles
Inclination of orbital plane to equator, assumed to be	65°
Perigee occurs going north at latitude	40·9° N.
Perigee distance from Earth's centre	3,561 ± 7 n. miles
Height at perigee over mean Earth	123 ± 7 n. miles
Apogee distance from Earth's centre	3,921 ± 8 n. miles
Height at apogee over mean Earth	484 ± 8 n. miles
Eccentricity	0·048 ± 0·002
Semi-major axis	3,741 n. miles
decreasing at	1 n. mile per day
Harmonic mean radial distance	3,733 n. miles
Period	96 min. 13·5 sec.
decreasing at	2·23 sec. per day
Rate of rotation of orbital plane (retrograde)	3·18 deg. per day
increasing at	0·0029 deg./day²
Rate of rotation of major axis (theoretical)	− 0·40 deg. per day

Track crosses latitude 51·71° N. at longitude 0·7° E. at time 21 hr. 08 min. 56 sec. G.M.T.

Ionospheric Phenomena

Observations of the amplitude of the signal received from the satellite have shown a complex fading pattern containing frequencies in the range 1–100 cycles per minute. Some of these are due to the spin of the satellite, others to the Faraday rotation effect; these latter fadings can be identified by the fact that their frequencies on the 20 Mc./s. and 40 Mc./s. records are in the ratio of about four to one. The variation of angle between the ray path and the Earth's magnetic field during transit complicates the effect, and so far a full analysis has not been made.

The faster type of fading occurred occasionally; simultaneous measurements made on three orthogonal dipoles have shown that this was not a rotating vector fading and that it could occur on one polarization alone. Such a fading at 50–60 cycles per minute was observed between October 11 and 14, but not thereafter.

A further interesting feature is the long duration of signals at a transit: the 20 Mc./s. signals in particular have been received for some 30–35 min. In addition, faint subsidiary signals have preceded and followed the main signal received during transit—this is especially marked on 40 Mc./s., and on this frequency there has been occasional long-distance reception, such as that noted on several afternoons when the satellite was over India.

The above evidence suggests that long-distance transmission from the satellite to the receiving station is by complicated ray-paths. At present the explanation of these is not clear, and further observations are needed to evaluate the various transmission mechanisms so far postulated. In this connexion the proposed programme of the Radio Society of Great Britain promises to be of value.

We are grateful to our colleagues at the Royal Radar Establishment, to the Post Office Engineering Branch, the B.B.C. receiving station at Tatsfield and the Marconi Co., Ltd., for making available the results of their Doppler measurements, and to Marconi's for assisting with the analysis.

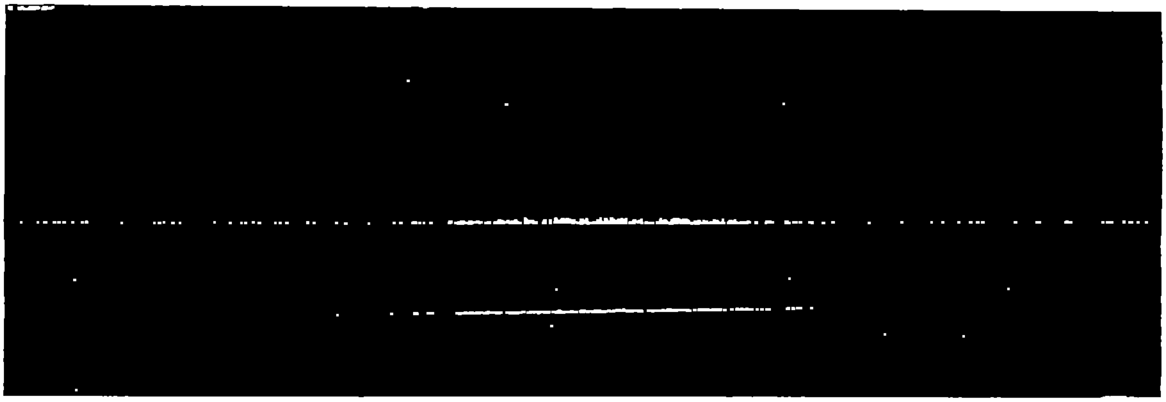
RADAR OBSERVATIONS OF THE FIRST RUSSIAN EARTH SATELLITE AND CARRIER ROCKET

By STAFF OF THE JODRELL BANK EXPERIMENTAL STATION, UNIVERSITY OF MANCHESTER

WHEN the first Earth satellite was launched on October 4 the radio telescope at Jodrell Bank[1] was still in an incomplete state. The instrument, which had been tested as early as August 2 on the reception of extra-terrestrial radio emissions, had afterwards given excellent results over a wide range of frequencies. However, a considerable amount of minor engineering work was in progress and, in particular, the telescope had not been tested as a radar instrument. Emergency arrangements were therefore made to couple to the telescope existing radar installations working in other parts of the Station.



1957 October 12, 2241 U.T.

Fig. 1. Radar echo from the Russian carrier rocket of the first satellite
Lower trace is an intensity-modulated range display with range limits 250 km. (lower edge) to 750 km. Rocket entered beam at range 500 km. and left at 550 km.
Centre trace is an amplitude-modulated display. Rocket reaches peak amplitude of 4 times noise. Upper trace gives seconds marks. (The double spaces are locating marks)

Table 1

	Frequency (Mc./s.)	Peak transmitter power (kW.)	Pulse duration	Pulse repetition rate	Overall feeder loss	Receiver noise factor	Receiver band-width
Equipment 1	120	10	2 milliseconds	10 or 20	15 dB.	5 dB.	500 c./s.
Equipment 2	36	10	150 micro-seconds	75	< 1 dB.	Limited by sky noise	5,000 c./s.

The two most appropriate equipments were: (1) the long-pulse 120 Mc./s. apparatus used in the lunar echo studies[2,3], and (2) a small 36 Mc./s. transmitter recently built for radio echo work on meteor trails in conjunction with the Schmidt cameras. Equipment 1 could not easily be shifted and was therefore connected to the telescope by a long length of transmission line and coaxial cable. The transmitter and preamplifier of equipment (2) was small enough to be mounted in the swinging laboratory just underneath the reflecting bowl of the telescope. In each case the primary feed was a dipole with reflector, mounted at the focal point so that there was cross polarization between the two feeds. The parameters of the two equipments are given in Table 1.

The improvised nature of the arrangements is obvious from these figures, and the only hope of success rested in the high performance of the telescope on these frequencies, that is, beam-width 8 degrees to half-power points, power gain 600 on 36 Mc./s.; beam-width 2·5 degrees to half-power points, power gain 6,500 on 120 Mc./s.

Equipment 1 was available for testing by the night of October 9, and with the telescope in automatic motion on the Moon satisfactory lunar echoes were obtained. Afterwards trouble developed with this apparatus, and the first radar contacts with the rocket and satellite were obtained with equipment 2 during the evening of October 11. Fig. 1 is a typical example of the echo from the rocket obtained on October 12. In this experiment the telescope was stationary, and the echo from the rocket is visible for 17 sec. as it crossed the aerial beam at a mean range of 530 km. Equipment 1 was available for use again by October 16, when it located the rocket at a range of 1,430 km. On subsequent occasions the telescope was set in motion after location of the target, and successful tracking was achieved over a part of the orbit. The film records obtained since these initial tests are only partially analysed; but Table 2 gives typical values of detection ranges, signal noise ratios and effective scattering cross-sections computed from these measurements.

Table 2

	Range (km.)	Signal/noise ratio	Effective scattering cross-section (sq. m.)
		(a) Rocket	
Equipment 1	1,300	3	10
Equipment 2	530	4	10
		(b) Satellite	
Equipment 1	1,000	< 1	< 0·6
Equipment 2	230	4	~ 0·4

On the expiry of the satellite batteries, requests were received to use the telescope for the location of the rocket and satellite, to assist with the computation of the orbits. In order to facilitate this work, equipment 2 was shifted to one of the elevated laboratories on the towers of the telescope, thereby removing the large feeder losses. The detailed analysis of the records to obtain more information about scattering areas and characteristics of the echo patterns is proceeding, and the results will be published in due course.

We are indebted to the consulting engineers for the telescope, Messrs. Husband and Co., of Sheffield, for their willing help and assistance in this programme, and to the staff of the Cavendish Laboratory, Cambridge, and of the Nautical Almanac Office of the Royal Observatory, Herstmonceux, for their predictions, which so greatly assisted the initial location of the rocket and satellite.

FURTHER RADIO OBSERVATIONS OF THE FIRST SATELLITE

THE radio signals from the first Russian Earth satellite were recorded at the University of Illinois Observatory during the period October 5–24 on 40 Mc./s. and on 20 Mc./s. This communication deals with the observations on 40 Mc./s. made with two-element interferometers, one with a north-south base-line of 5·45 wave-lengths, the other with a north-south base-line of 1 wave-length. The first instrument was constructed during the night of October 4–5, the second on October 11. The latter was fed out of phase for lobe-ambiguity resolution. The results were recorded on Esterline-Angus graphic recorders running at 1 ft./min.

The interpretation of the records was complicated by the fact that all the eleven lobes of the pattern of the main north-south interferometer never appeared on the record of any one passage of the satellite. However, it proved possible to overcome this difficulty, particularly after October 11, when the second instrument came into use. The instruments were located on the parallel N. 40° 1·1′. The times at which the first artificial Earth satellite crossed this parallel, together with estimates of the altitude above the horizon at the moment of closest approach, were communicated as rapidly as possible to the Smithsonian Astrophysical Observatory, Cambridge, Mass., and the Naval Research Laboratory, Washington. The mean absolute error in the times of crossing was 3s.

Since the radio-signals ceased, the computations have been refined. The period of the satellite and the regression of the nodes of its orbit can be deduced from our observations. The best representation of the period (P) during the interval October 5–24 is:

$$P = 96\text{m. } 09{\cdot}8\text{s.} - 0{\cdot}1293\text{s.}n - 7{\cdot}797\text{s.} \times 10^{-5} n^2 \quad (1)$$

where n is the number of revolutions since our adopted zero, which was the southbound crossing of our parallel on October 5d. 13h. 30m. 01s. U.T. The regression of the nodes can be expressed as follows: the local mean solar time at the point of southbound crossing of our parallel is:

$$(8\text{h. } 11\text{m.} \pm 2\text{m.}) - (1{\cdot}100\text{m.} \pm 0{\cdot}006\text{m.})n$$

The probable errors shown are calculated from internal consistency. The observations were made under the direction of George W. Swenson, jun., and the interpretation of the results was carried out by Ivan R. King with the assistance of Stanley P. Wyatt, jun.

These formulæ are based on the records obtained at our station alone. On October 26 a radio broadcast from Moscow mentioned that the period was 95·31m. During that day, n would increase from 313 to 318 between 9h. and 18h. U.T. Thus formula (1) would give periods ranging from 95·36m. to 95·35m. On October 28, the Smithsonian Astrophysical Observatory released a statement that, on October 25d. 2h. 25m. U.T., the period was 95·44m., and the daily variation of the period was − 2·4s. It is not known whether our results entered into the computation of those of the Smithsonian. October 25d. 2h. 25m. corresponds to $n = 294$ and this gives $P = 95{\cdot}42$m., with a daily variation of − 2·6s.

Records on 20 Mc./s. were also obtained under the direction of Edgar C. Hayden and these, together with the 40 Mc./s. results, are expected to furnish considerable information about the ionosphere. These records have not yet been analysed.

Nov. 1.

THE 40 Mc./s. frequency of the first Russian Earth satellite has been measured at Chelmsford for the condition of zero Doppler effect.

The method adopted presupposed that the signal might be modulated at the source or during propagation in such a way as to make fully automatic measurements difficult, so the fine component of local comparison frequency was obtained from an audio oscillator steered manually to follow the Doppler variations. For a high percentage of the time the 'steering' error was held less than 2 c./s. by using a circular time-base on a cathode ray oscilloscope. The audio oscillator output was connected to a frequency recorder having scales of 4·5 in. per 1,000 c./s. and 1 in. per 30 sec.

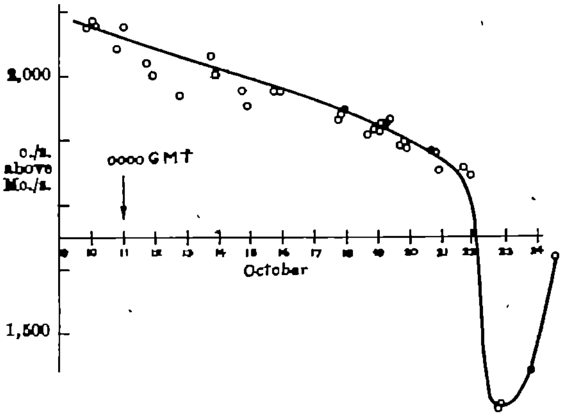

Fig. 1

The S-shaped Doppler curves obtained were remarkably clean and symmetrical, so that the frequencies and times corresponding to nearest approach (zero Doppler effect) could be read off with useful accuracy. Fig. 1 shows the frequencies of zero Doppler effect deduced in respect of 37 orbits observed between October 9 and 24, 1957. Signals were not heard after 1843 G.M.T. October 24.

The maximum rates of change of frequency observed for the various orbits covered the range of 33–4·5 c./s./s., corresponding to approximate slant-range values of 224–1,500 km. respectively.

The datum of the local 40 Mc./s. comparison frequency was known to within 1 part in 10^8.

Great Baddow,
Chelmsford, Essex.
Oct. 30.

HIGH-POWER radar equipment has been installed in the 45-ft. diameter radio telescope at the Royal Radar Establishment, Malvern, to make radar observations of the Russian Earth satellites and rockets. A radar echo from the rocket of the first satellite was detected on October 30, at a distance of 864 miles (750 nautical miles). The rocket was then east of Iceland and at a height of about 220 miles. A wave-length of 10 cm. was used, and the radio telescope has a narrow beam of about half a degree. Using predictions supplied by H.M. Nautical Almanac Office, the radio telescope was set in the direction of the path of the rocket. A strong radar echo was observed as the rocket passed through the field of view of the radio telescope.

Ministry of Supply.

ROCKET OF THE FIRST EARTH SATELLITE

THE rocket accompanying the first Russian Earth satellite was widely observed in Ireland during October 11–16, owing to the favourable situation of the orbit. More than twenty photographs have been received and measured at Dunsink Observatory, and are consistent with a height of 430 km. The tracks show marked variations of brightness with a period of about one minute, due to rotation of the rocket (Figs. 1 and 2).

Further visual observations indicate that the rocket passed approximately centrally over Ireland on October 26d. 18h. 44m.

The combined observations lead to an orbital period of 95m. 53s. at October 11·23d., decreasing uniformly by 4·13s. a day to 94m. 49s. at October 26·78d. The corresponding decrease in semi-major axis is 3·4 km. a day. The precession of the node is approximately 3·3° a day.

RADIO PICTURES OF THE SUN

By W. N. CHRISTIANSEN, D. S. MATHEWSON and J. L. PAWSEY
C.S.I.R.O. Radiophysics Laboratory, Sydney

WE have recently put into operation an instrument which gives pictures of the Sun in the 'light' of 21-cm. radio waves.

The extension of knowledge concerning the exterior of the Sun has to a great extent followed the introduction of special techniques which have enabled us to see progressively higher levels in the solar atmosphere. Thus the photosphere and sunspots are seen in white light. The spectroheliograph gave the first comprehensive picture of the chromosphere with its prominences, flares and plages. Above this lies the corona, which was known from eclipse observations, but which has only in the past few decades been regularly observable using Lyot's coronograph. Even now the corona is observable optically only beyond the limb, and the problem of observing the corona in front of the disk of the Sun may well be insoluble optically.

With the discovery of radio emission from the Sun and the recognition that this emission must, at suitable wave-lengths, originate in the corona, it became possible in principle to obtain pictures of the corona over the disk. But to get a detailed picture of the Sun, which is only ½° in diameter, the angular resolution required appeared prohibitive. Over the years, information was obtained by devious methods, by circumstantial evidence based on the correlation between sunspots and radio emission, through eclipse observations, and, most effectively, by regular day-by-day observations using knife-edge beams only a few minutes of arc in width.

These have demonstrated that the radio sun at decimetre wave-lengths shows a background due to thermal emission from the bulk of the lower corona, together with bright patches which last for periods of the order of months, and are related in some way to optically active regions. The current hypothesis concerning the cause of the bright patches is that they are due to thermal emission from unusually dense and hot regions in the corona.

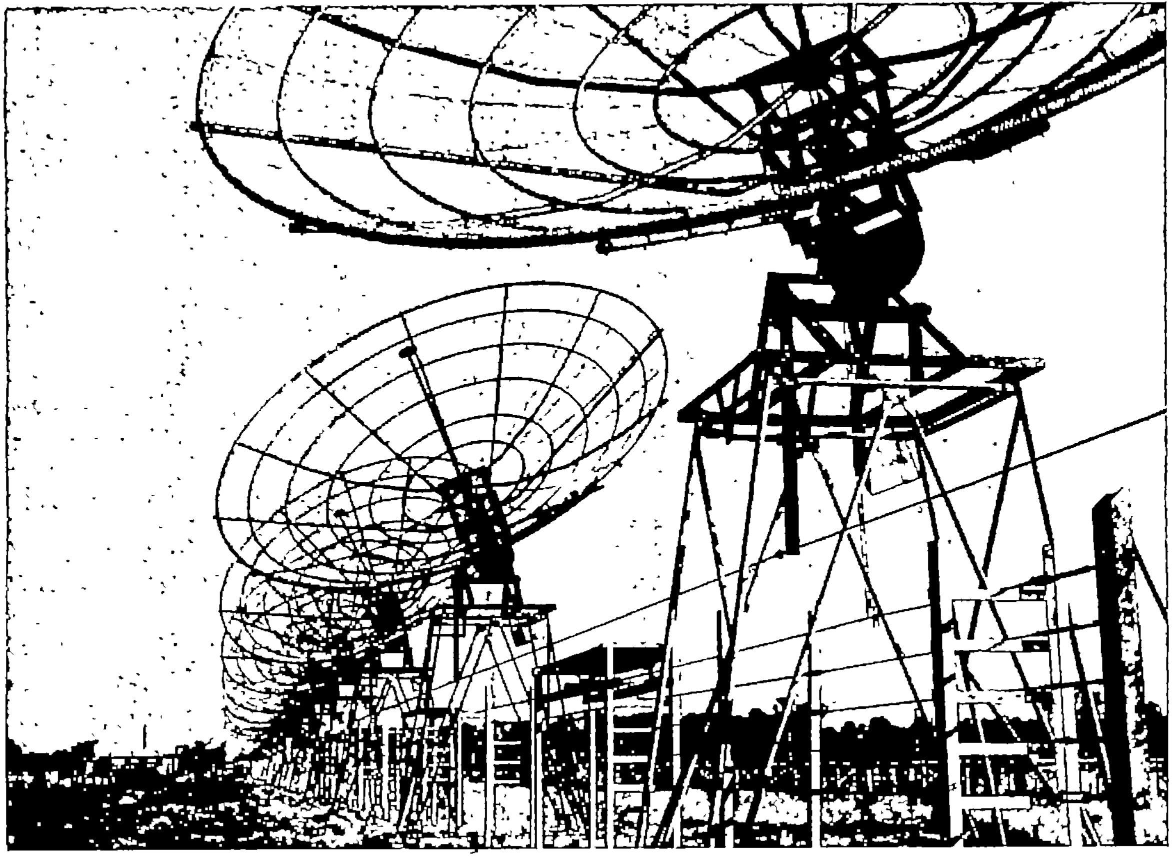

Fig. 1. One arm of the radioheliograph

The form of the background due to the quiet sun, which gives useful information concerning the electron temperature and density distributions in the solar atmosphere, has been determined at a time of sunspot minimum. But, though it is suspected to vary during the sunspot cycle, previously available techniques were not sufficiently powerful at times of high solar activity properly to differentiate between the background and the bright patches. Similarly, there is a suspicion that the slowly varying component due to the bright patches may change its characteristics with the sunspot cycle.

Our new instrument, which we may call a radioheliograph, promises regular pictures of the lower corona. A photograph of this instrument is shown in Fig. 1. A similar instrument, working on a longer wave-length, would respond to radiation from the upper corona.

The radioheliograph combines the principles of the multi-element, or grating, interferometer[1] and the Mills cross[2]. It consists of two rows of 19-ft. diameter parabolic aerials arranged in the form of a cross.

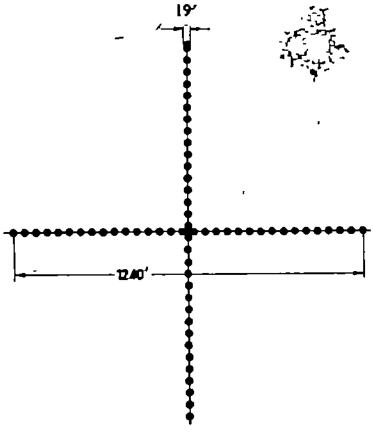

Fig. 2. Plan view of radioheliograph

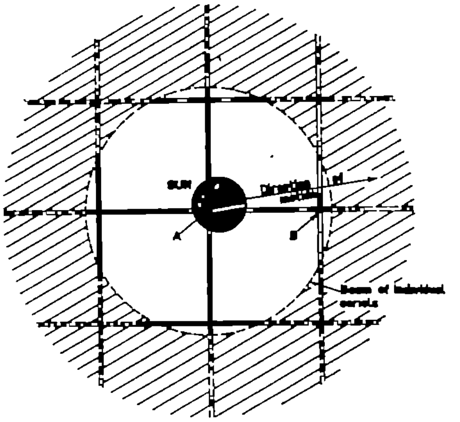

Fig. 3. Position of the aerial beams (small black circles) of the radioheliograph at the intersections of the knife-edge beams of the two multi-element interferometers. The solar disk is shown being scanned by one of the aerial beams

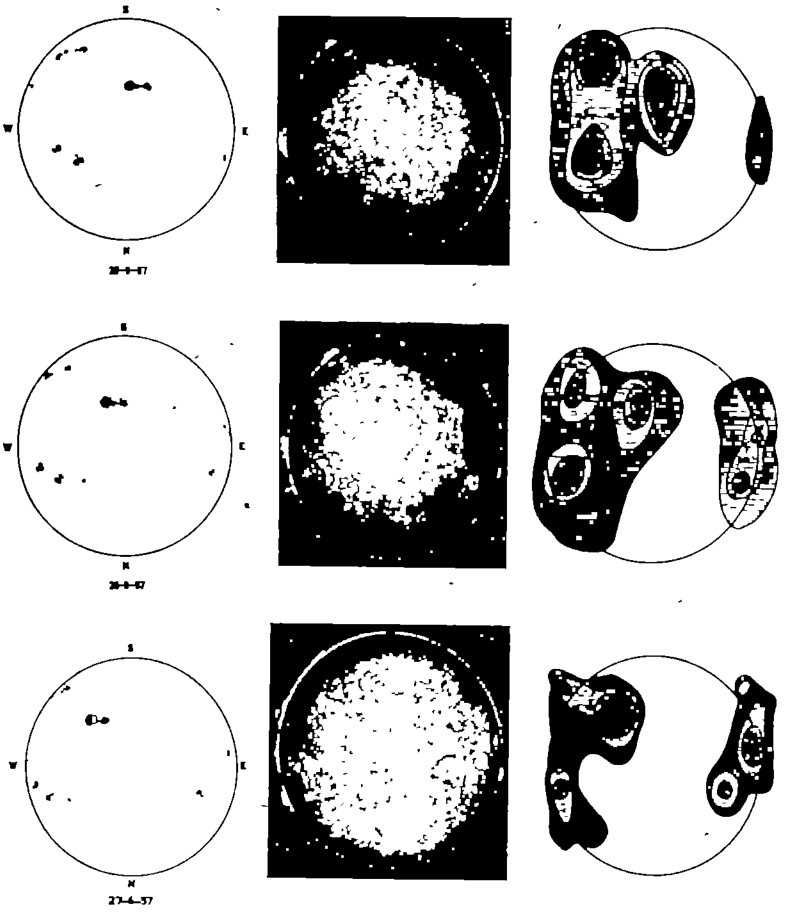

Fig. 4. Comparison of white light sketches, Hα spectroheliograms (obtained from the Division of Physics, C.S.I.R.O., Sydney), and 21-cm. brightness contours on three successive days in June 1957. The three pictures are related to emission from the photosphere, chromosphere and corona, respectively. In the radio picture only the contours indicating high radio brightness are drawn. The quiet sun-level is not shown

Each row has 32 paraboloids spaced at 40-ft. intervals, so that the overall length is 1,240 ft. The individual paraboloids are fed through a branching feeder system similar to that used in the original 32-element interferometer, and the combination gives a series of knife-edge beams in the sky. The arrangement is shown in Fig. 3, the north–south arm giving a series of east–west beams, and the east–west arm, a series of north–south ones.

The signals from the two arms are combined, as in the Ryle interferometer, alternately in-phase and out-of-phase, and the component of the output which alternates in synchronism is recorded. The system has a directional diagram which is the product of those of the two arms, that is, it consists of the array of pencil beams drawn black in Fig. 3. For directions near the zenith these are 3′ of arc in diameter and the spacing between adjacent beams is 1°, so that only one falls in or near the Sun at one time.

As the Earth rotates the beams move together across the celestial sphere, and one of them, marked *A* in Fig. 2, scans a strip on the Sun. The adjacent beam *B* scans a strip which may be different from the first, either if the phases of the north–south system are re-adjusted, or if, as is the case away from noon, the motion of the Sun is not parallel to the east–west beams. In this way a picture of the Sun is built up in the manner of a television picture, in a period of about half an hour. All the 64 paraboloids are turned on equatorial axes to continue pointing at the Sun during this time.

The equipment began operation in June 1957, and we hope to make routine observations over the International Geophysical Year. Some of the early radio pictures are shown in Fig. 4, together with optical pictures in Hα and in white light. These show successively lower levels in the solar atmosphere, lower corona, chromosphere and photosphere respectively. In the radio pictures only the bright patches have been shown pending adequate checks on the directional diagram of the equipment.

The close, but not perfect, correspondence between radio bright patches, chromosphere plage and sunspots is evident. Perhaps the most interesting feature of these early observations is the way in which the bright areas can fall outside the visible disk. Thus the bright area in the south-west which is outside the optical limb on June 27 provides a measurement of a very direct kind of the height in the corona at which the emission originates. The previous evidence was indirect and obtained at the minimum part of the solar cycle. It may happen that the height systematically changes during the sunspot cycle. It is also interesting to note that the great height or extent of the radio-emitting region permits observations of regions for which the associated sunspots and optically active area may be out of sight beyond the limb of the Sun. The appearance of bright areas on the east limb may prove useful in predicting the appearance of active regions. An important active region made its appearance around the east limb some days later in the position indicated by the radio bright patch in the extreme south-east on June 27.

Radio observations have now enabled us to study one more level in the solar atmosphere. Similar advances in the past have revealed new and unexpected phenomena, but have contributed surprisingly little to the physical understanding of the Sun. We hope that in due course our observations may contribute both new phenomena and understanding.

LIPID GLOBULES IN CELLS

By Dr. JOHN R. BAKER

Cytological Laboratory, Department of Zoology, University Museum, Oxford

THE course of cytological research would have been very different if chromatin had been as invisible in routine microscopical preparations as lipid globules are, and lipid globules the most evident objects in cells. There has been a curious tendency to disregard lipid globules, or to mention them in an off-hand manner. People who speak with great accuracy about proteins, nucleic acids and carbohydrates often tend to dismiss these globules as mere 'fat droplets'—as though this group of chemical compounds were somehow of a lower social order than others.

One reason for the neglect of these cytoplasmic inclusions is perhaps the confusion with droplets of adipose fat. It is important to realize that the great majority of cells contain lipid droplets in the cytoplasm, but that adipose fat is an unusual constituent except in the particular cells that are set aside to accumulate it. When an animal is starved, the adipose fat is used up; but the lipid droplets that occur in nearly all cells are retained. I am concerned here with those lipid droplets that do not appear to function as food reserves.

In some cells, such as neurones, the lipid droplets are distributed at random throughout most of the cytoplasm; but in many kinds of cells, especially those that have a clear polarity, they occupy a particular position. Globules of adipose fat, on the contrary, do not ordinarily accumulate in any special place in a cell.

It is unfortunate that we have no positive histochemical method for determining the presence of triglycerides, but must rely on a process of exclusion of other kinds of lipids. It is therefore impossible to deny that triglycerides may occur in various lipid globules of the kinds I am discussing; but the positive evidence of histochemistry suggests that these globules consist mainly of more complex substances. Very often it is possible to prove the presence of phospholipids by application of the acid–hæmatein test. Generally there are indications also of the presence of cerebrosides. Thus the periodic acid/Schiff test gives a positive result, though there may be no other indication of the presence of a carbohydrate. This suggests that the periodic acid/Schiff reagent is reacting with the hexose of the cerebroside molecule. In some cases, when a piece of tissue has been fixed in pure acetone, the lipid globules are darkened by sudan black. This is corroborative evidence of the existence of cerebrosides, for nearly all other lipids would be extracted by acetone. The available evidence suggests that lipid globules are often composed largely of phospholipids mixed with cerebrosides. Should this suggestion prove correct, it may be found convenient to speak of 'cerephos' globules. It must be remarked, however, that a positive reaction to the periodic acid/Schiff test by a purely lipid globule does not prove the presence of cerebroside. The sphingosine of sphingomyelin contains the groups necessary for a positive reaction with the periodic acid/Schiff reagent, and sphingomyelin indeed reacts positively[1]; unsaturated fatty acids are also capable of giving a positive reaction[1,2].

Certain cytoplasmic globules that consist mainly of lipid appear to contain also small quantities of protein and carbohydrate. Chou[3] has described such globules in the neurones of gastropods.

In fixed preparations, lipid globules often appear to be duplex in character. We read of externum and internum, of chromophil and chromophobe constituents. The so-called 'dictyosome' has a chromophobe core and a chromophil cortex, the latter often appearing as a ring or crescent in optical section. Such appearances are rarer in fresh preparations, and there is reason to believe that in some cases a dictyosome was nearly homogeneous in life. It is relevant to consider the different causes that may make a homogeneous or nearly homogeneous body appear duplex.

(1) The artificial appearance of a cortex and medulla may be produced by purely optical means. In a most valuable paper, Oettlé[4] has shown that 'optical membranes' of considerable thickness may be formed around objects that are in fact homogeneous. These misleading appearances can be produced not only by dark-ground and direct microscopy, but also by positive phase-contrast.

Spherical bodies such as lipid globules are particularly apt to give misleading appearances with phase-contrast. The edge of a globule may appear black or grey because there is here the right thickness to give the necessary retardation of light for this effect. The light that passes through the centre of the globule, however, may be so much retarded as to give reversed contrast and appear bright. A black ring may thus be produced, though the globule is homogeneous.

It has been shown by Chou and Bradbury[5] that with positive phase-contrast an error of centration of the condenser may transform a black ring around a globule into a crescent.

(2) It was shown long ago by Altmann[6] that lipid globules are sometimes only blackened by osmium tetroxide on the outside, so that they appear as rings in optical section. Altmann called these *Ringkörner*. He found that they were not present initially, but only when tissues fixed in osmium

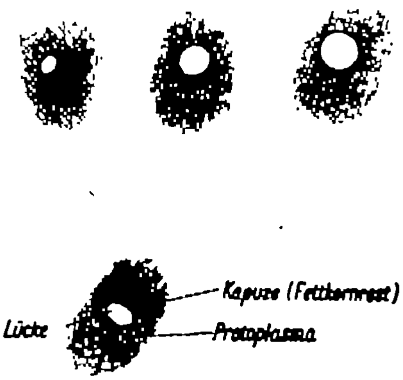

Fig. 1. Three *Ringkörner* and a cap or hood (*Kapuze*) formed by partial solution of lipid globules: osmium preparations. (From Starke, ref. 8)

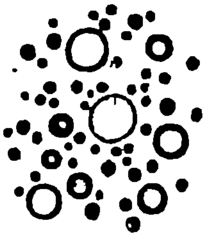

Fig. 2. Globules of fixed albumose, dyed with picric acid and acid fuchsin. Although the globules are homogeneous, the outer part is strongly coloured by acid fuchsin, while the interior takes the pale yellow of picric acid. (From Fischer, ref. 10)

tetroxide solution had been brought into ethanol. He attributed their formation to partial solution of the lipid droplet by ethanol[7]. The subject was carefully investigated by Starke[8], who found that if a lipid droplet were surrounded by fixed cytoplasm, it did not shrink evenly when part of it was dissolved away by ethanol; a spherical hole was left, to the walls of which the insoluble part of the lipid, blackened by osmium, adhered. The blackened remnant of the original lipid looked like a ring, crescent, or cap in optical section (Fig. 1). Many 'dictyosomes' are probably of this nature.

(3) Cain[9] has shown that sudan black is only able to colour lipids when they are liquid or semi-liquid. If a globule consisting of mixed lipids were treated in such a way that the solid constituents crystallized out separately from the liquid, only the latter would be coloured by sudan black.

(4) Osmium dioxide or silver is sometimes deposited on the surface of a cytoplasmic inclusion in such a way as to produce an artificial membrane around it. The thickness of the deposit depends on the period of osmication or silvering.

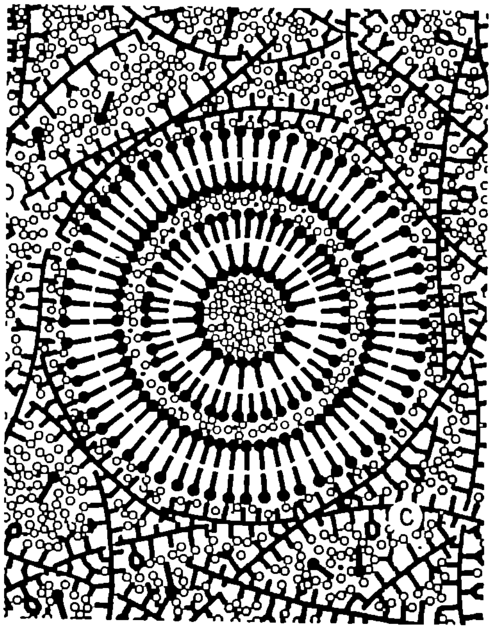

Fig. 3. Diagram showing the lamellar arrangement of hydrophil lipids in a globule consisting of such lipids and water. Water molecules are represented by small circles; hydrophil lipids by short rods with spherical swellings at the hydrophil end of the molecules; proteins by long, sinuous threads with short lateral projections. (From Schmidt, ref. 14)

(5) When two dyes are used in staining a cytoplasmic inclusion, one of them may penetrate more readily and thus colour the inside, while the other, a stronger but more slowly penetrating dye, may colour the outside. A misleading appearance of cortex and medulla may thus be produced. This was shown at the end of the last century by Fischer[10], who worked with homogeneous granules of fixed albumose (Fig. 2). Picric acid and acid fuchsin are a pair of dyes particularly prone to give misleading appearances of this sort (especially in Altmann's method for mitochondria, and its variants).

These facts must make us chary of accepting the real existence of cortex and medulla in lipid globules. In some cases, however, there can be no doubt that a lipid cortex encloses a non-lipid medulla. This structure can only be established by painstaking study of the living cell, preferably with the interference microscope. The fullest investigation of this kind is that of Roque[11] on the paranuclear bodies of the spermatocyte of the snail.

Certain globules, in which no substances other than lipids can be demonstrated by histochemical tests, have very low refractive indices. This applies, for example, to the lipid globules in the neurones of the locust, which, as Shafiq[12] showed, have almost the same refractive index as the cytoplasm and are therefore nearly invisible in the living, unstained cell. Similar globules in the neurones of the snail have been shown by Ross and Chou[13] to have a refractive index of only 1·416, which appears to be less than that of any known lipid.

Since no substance other than lipid can be demonstrated in these globules, it seems almost certain that the other component must be water. Now phospholipids, which occur in these globules, have a special affinity for water. As a result of his studies with the polarizing microscope, Schmidt[14] concluded that, in the presence of water, certain lipids tend to arrange themselves in the form of curved, concentric lamellæ (Fig. 3). It is therefore interesting that the electron microscope shows curved, concentric lamellæ in certain lipid globules. The acroblast of the insect spermatid provides an example[15]. The acroblast is undoubtedly a duplex body, with lipid externum and non-lipid internum. In electron micrographs the externum appears in the form of numerous curved, concentric 'double membranes'. It seems probable that these are the expression, at the level of resolution of the electron microscope, of an underlying lamellar arrangement at the molecular level, caused by the association of phospholipids with water. It has been shown that pure lipids, fixed with osmium tetroxide, may exhibit a lamellar structure in electron micrographs[16]. It is possible, however, that substances other than phospholipids are capable of producing lamellar structures in electron micrographs.

Secretion products of the most varied kind first appear within lipid droplets. A multitude of examples of this process has been assembled by Hirsch[17]. The secretion of the acrosome by the acroblast is perhaps the most familiar one. The Worleys[18] followed step by step the origin of fatty and protein yolk within lipid globules in the living embryos of gastropods. It seems likely that the lipid envelopes prevent the synthetic enzymes from diffusing away, but we have not yet any comprehensive theory of such syntheses. We are also ignorant of the significance of those lipid droplets in which, so far as is known, secretory products do not appear.

NUTRITION OF THE VERY YOUNG

THE 111th meeting of the Nutrition Society (which was also the 50th meeting of the Scottish Group), held in Queen's College, Dundee, on September 21, took the form of a symposium on "The Nutrition of the Very Young". The chairman was Prof. J. L. Henderson (Department of Child Health, Queen's College, Dundee).

In the first paper, on "Nutrition in the Neonatal Period", Dr. C. A. Smith (Boston Lying-in Hospital, Boston, Massachusetts) pointed out that the nutritional status of newborn infants from apparently well-fed mothers can vary appreciably. There would appear to be little proof of a constant association between maternal and fœtal nutrition. It may be that, with the relatively slow growth of the human fœtus when compared with some animals, all nutritional requirements can be met by a maternal diet which is marginal or sometimes sub-marginal. This being so, the variations in fœtal weight so commonly observed may arise from factors other than maternal diet or stores. Abnormalities in weight and morphology of the placenta have been shown to give rise to a considerable degree of fœtal under-nutrition, and infants thus retarded show rapid growth once dietary energy is available after birth. The nutritional status of the fœtus is therefore a product, not only of maternal nutrition, but perhaps also of uterine and placental factors which cannot all be readily inspected at delivery.

In regard to the diet of the newborn infant, Dr. Smith considered that natural feeding of infants was probably not the customary method in his part of the United States. Indeed, one school of thought in that country has brought spoon-feeding of semi-solid foods to the second and even the first week after birth, but considerable care must be taken to ensure that correct amounts and proportions of nutrients are supplied.

Premature infants in the Boston Lying-in Hospital are bottle-fed from a human milk bank for one or two months, but this is a rare eventuality in the United States, where in many nurseries for premature infants an artificial mixture of modified cow's milk is fed from birth. The reason for preferring human to cow's milk is its reliable digestibility and the reduced osmolar load of its electrolytes for renal excretion. Dr. Smith pointed out that the greater nitrogen retentions and gains in weight made by infants on artificial foods require evaluation by long-term rather than by short-term work which might be misleading. Recent work in Chicago showed that the large and prompt gains frequently observed after introduction of artificial feeding were often associated with over-retention of sodium, chloride and water. After renal adjustment to the increased electrolyte content of the diet, a return to isocaloric feeding of human milk resulted in a temporary loss of weight and negative sodium and chloride balance. There is a danger in artificial feeding that 'supermineralization' may be forced on the growing infant. Dr. Smith has not been giving supplements of iron to term infants in his care for a few weeks after birth, because most of them will be receiving iron in cereal foods at three months, and experiments have shown that it is not until around that time that iron begins to be absorbed from the infant food.

Vitamin supplements given now are less than those given 15–20 years ago. Daily dosage of a concentrate containing 50 mgm. of ascorbic acid, 1,000 units of vitamin D and 5,000 units of vitamin A is begun late in the second or third week.

Dr. F. E. Hytten (Obstetric Medicine Research Unit, Medical Research Council, Foresterhill, Aberdeen) read the second paper, entitled "Some Theoretical and Practical Difficulties in Neonatal Feeding".

During the latter half of the nineteenth century and up to the First World War, propaganda for breast feeding was undoubtedly justified because of the poor quality of human-milk substitutes and the poor conditions of hygiene prevailing; but it is doubtful whether such emphasis need now be laid on breast feeding, especially in view of the many household responsibilities which the modern mother has to bear during lactation. The fact that the fall in infant mortality and in breast-feeding rate since 1929 has been closely parallel at least indicates that there is no longer the same need to appeal for breast feeding if it is a burden to the mother.

The most common complaint of the breast-feeding mother is general fatigue. This is understandable in view of the extra work entailed in caring for and feeding the baby, especially over the first few weeks when she can expect no more than four hours continuous sleep. Fatigue is most noticeable among women without domestic help. Those mothers living with relatives who could relieve them of household duties while they were feeding the baby were less affected by reason of lower energy expenditure. Fatigue is accentuated by worry, and worry is more characteristic of mothers who are breast feeding. Many breast-fed babies cry excessively, even when gaining weight satisfactorily and thriving in other respects, and it is difficult to convince the mother that hunger is not the cause. A change to bottle feeding is often desirable in such a case and this in itself often stops the crying.

Under modern conditions of living, if the mother is having difficulty with breast feeding or is unwilling to maintain it through dissipation of her available energy in household tasks, it is more practical and better for both her physical and mental health to encourage her to feed the baby by bottle.

In his paper entitled "The Nutrition of Young Animals", Dr. T. R. Preston (Rowett Research Institute, Aberdeen) considered problems encountered in rearing calves and pigs, the only mammals commonly reared both artificially and naturally.

Young pigs are normally allowed to suckle for eight weeks with supplementary *ad lib.* feeding of a dry meal from about the fourth week. However, by rearing from soon after birth on a synthetic diet, an extra litter of pigs can be produced every two years from each sow.

Because of the economic value of cow's milk for human consumption, only pedigree calves are normally suckled. The majority of calves are reared artificially soon after birth on varying amounts of cow's milk or milk substitute.

The successful rearing of pigs without colostrum is almost impossible, because the pig, unlike the human, relies on colostral transfer of immunity, the placenta being impervious to antibodies. Piglets are therefore allowed to suckle for a few days before feeding artificially. Growth and mortality have been variable on artificial feeding from two days of age and as much as 61 per cent mortality has been recorded between three days and eight weeks. The system of feeding artificially from the third day has therefore only found limited application.

Weaning at ten days has met with most success in practice. A dry meal mixture based on dried skimmed milk powder with added starch, glucose, sucrose, fishmeal, minerals, vitamins and antibiotics is fed with water supplied separately. Weaned in this way the pig eats very little at first, but after a preliminary check period of 3–15 days food and water are consumed in increasing amounts, and growth is rapid, so that at eight weeks artificially reared pigs are often as heavy or heavier than pigs reared naturally.

The more successful rearing from ten days of age is associated with the development, during the first week after birth, of enzyme systems capable of digesting dietary starch and sucrose.

Like the young pig, the calf depends on colostrum for immunity from infectious diseases, and this is supplied by allowing it to suckle for three days or by feeding colostrum from a bucket. It is then usual to feed whole milk or a reconstituted synthetic or semi-synthetic milk for 8–12 weeks before weaning on to dry meal and roughage. Mortality is around 8 per cent.

Up to about four weeks of age lactose and glucose are the most suitable carbohydrates for synthetic milk diets because during early life the enzyme systems for splitting starch and sucrose are just developing.

The sooner the calf becomes a functional ruminant the more cheaply it can be reared. The major stimulus to rumen development is ingestion of solid food, and rumination in calves given early access to solid food begins when they are two to three weeks of age. It has been shown recently that calves made adequate growth when fed from three weeks of age on a simple dry meal mixture with hay and water.

Speaking on "Idiopathic Hypercalcæmia of Infants", Dr. R. G. Mitchell (Department of Child Health, University of St. Andrews) pointed out that, in eighteen cases studied during four years, the age of onset of the illness ranged from the third to the ninth month. Symptoms were anorexia, loss of weight, vomiting, constipation and a plasma calcium-level greater than 12 mgm./100 ml. In eleven cases the blood urea-level was greater than 50 mgm./100 ml. The clinical features and high rate of calcium absorption from the intestine suggested a vitamin D effect. Investigation showed that intakes of vitamin D were greater than 1,000 I.U. daily, with eleven cases taking more than 2,000 I.U. daily. Intakes of the latter order have been shown to interfere with child growth but are much less than intakes reported for vitamin D poisoning. Although the children affected may have a lower requirement than normal for vitamin D, it is possible that there may be factors which enhance vitamin D activity. However, neither sunshine, deficiency of essential fatty acids, abnormal constituents of cod liver oil nor administration of alkali as milk of magnesia were found to be likely causes. It was noted that in about a third of the cases a history of infection was associated with the illness and in seventeen of the eighteen cases dried cow's milk fortified with ergocalciferol was fed. Thus calcium intake would be high and a major part of the ergocalciferol would be given in milk, a circumstance which has been shown to enhance activity of the vitamin.

Most infants recover spontaneously if given a diet low in calcium without added vitamin D. Autopsy on three who died showed extensive nephrocalcinosis. The twelve surviving children, whose cases were followed up, have apparently made a complete recovery although still below average height and weight.

The final paper on "Hypercalcæmia in Infants and Young Animals" was read by Dr. A. M. MacDonald (Royal Hospital for Sick Children, Glasgow), who discussed certain aspects of renal pathology in infants and in young animals. The severe form of kidney lesion invariably shows stainable calcium deposits, but with it a destructive granulomatous type of lesion is found often lacking in stainable calcium. Stainable calcium deposits are not therefore considered essential in identifying early stages of the disease.

In both mild and severe form the lesion can be found in infants dying of a wide range of diseases such as hypophosphatasia, gastro-enteritis and constipation. The ages of children showing this lesion vary from four to eighteen months with a peak at nine months. It is suggested that where similar lesions are found by chance there is likely to be an association with hypercalcæmia, excessive vitamin D intake or a metabolic defect involving vitamin D.

To follow the evolution of the kidney lesion, calves, rabbits, guinea pigs, rats and mice were given exceptionally large doses of vitamin D and killed serially.

It is known that vitamin D_2 was present in virtually all infant foods in daily doses of 3,000–4,000 I.U. These amounts are well above the dose of 700 I.U./day accepted as adequate for prevention of rickets.

The number of infants dying from widely different causes and showing this renal lesion suggests that hypercalcæmia in infants might be common owing to vitamin D additives in food.

It is expected that the papers presented at the meeting will be published *in extenso* in the *Proceedings of the Nutrition Society*, Vol. 17, No. 1, early next year.

J. DAVIDSON

NEWS and VIEWS

Nobel Laureates:

Sir Alexander Todd, F.R.S.

Sir Alexander Todd, professor of organic chemistry at the University of Cambridge, has been awarded the 1957 Nobel Prize for Chemistry, for his work on co-enzymes. On leaving Glasgow in 1929, Todd spent two years in Frankfort working on bile acids; he then went to Oxford, where under the stimulating leadership of Sir Robert Robinson he did valuable work on the anthocyanins. In 1934 he transferred to Edinburgh, where he devised a synthesis of aneurin (vitamin B_1). After a spell at the Lister Institute, he was appointed in 1938 to the Sir Samuel Hall chair of chemistry at Manchester in succession to Sir Ian Heilbron. It was there that he became interested in the synthesis of nucleosides and soon in the much more difficult problem of their phosphorylation, work which he continued so fruitfully from 1944 onwards at Cambridge. Brilliant achievements were the synthesis of adenosine diphosphate in 1947, of adenosine triphosphate in 1949 and of flavin-adenine dinucleotide and uridine triphosphate in 1954. Sir Alexander also played a major part in the recent collaborative work on the structure of vitamin B_{12}. The profusion of the researches he has carried out or inspired can be judged from the fact that his name appears in the author index of the *Journal of the Chemical Society* for almost every one of the last twenty-five years, usually against several papers. Among many awards he has received both the Davy Medal and the Royal Medal of the Royal Society. Sir Alexander has been chairman of the Advisory Council for Scientific Policy since 1952; he was knighted in 1954.

Dr. Chen Ning-yang and Dr. Tsung Dao-lee

The Nobel Prize in Physics has this year been divided between Dr. Chen Ning-yang and Dr. Tsung Dao-lee. They both worked with the late Prof. E. Fermi at Chicago and are now respectively at the Institute for Advanced Studies, Princeton, and Columbia University, New York. Their suggestion that parity is not necessarily conserved arose from a study of the well-known puzzle in meson physics: that theta- and tau-mesons, which in other respects are apparently identical particles, decay into two and three pi-mesons, respectively. This led them to examine the experimental evidence for the 'law' of conservation of parity, and they concluded that in the case of weak interactions, such as those involving beta-decay, the experimental evidence was quite inadequate. They suggested a number of experimental tests, the first of which to be carried out was the study of the angular distribution of beta-rays from polarized nuclei. This was carried out at the U.S. Bureau of Standards earlier this year and showed that parity was not conserved. As soon as this result was known privately, a second experiment was carried out at Columbia University on the decay of pi- and mu-mesons which showed that the positive electrons from the decay of mu$^+$-mesons are preferentially emitted in the direction opposite to that in which the mu-meson is travelling. Confirmation of these results was provided by further experiments at many other laboratories, and the suggestions of Drs. Yang and Lee have led to the devising of experiments in which conservation of parity is studied in cases involving other interactions, as well as to a precise measurement of the magnetic moment of the mu-meson.

Prof. Daniel Bovet

The award of the Nobel Prize for Physiology and Medicine to Prof. Daniel Bovet will give pleasure to all chemists and pharmacologists who are concerned in the discovery of new drugs. At the Institut Pasteur, which he joined in 1932, and since 1948 at the Istituto Superiore di Sanità in Rome he has made a long series of discoveries in chemical pharmacology, many of which have led to important advances in medicine. He was one of the outstanding workers during the exciting years (for medicine) 1937–44. Soon after Domagk's announcement (1935) of the curative action of 'Prontosil' in acute streptococcal and staphylococcal infections, a group of workers including Bovet at the Institut Pasteur demonstrated that sulphanilamide was equally curative, but, unlike 'Prontosil', was bacteriostatic *in vitro* (1935–37). This work focused attention directly upon the sulphanilamide structure and away from azo dyes, with immense consequence for medicine. During the same period Bovet had been investigating the pharmacology of aryloxyethylamine derivatives which had oxytocic and anti-adrenaline properties. He discovered that some of these compounds, and particularly thymoxyethyldiethylamine, had anti-histamine properties (1937). In the same year he and Staub observed that anilinoethyldiethylamine also had anti-histamine properties. This discovery was the origin of a great outburst of work, at first mainly in France and later elsewhere, which led to a wholly new class of drugs, the highly active and clinically useful anti-histamines of the ethylenediamine type, of which mepyramine (1944) was Bovet's crowning achievement in this field.

Shortly after Harold King's brilliant elucidation of the structure of tubocurarine, Bovet began to investigate synthetic substitutes for this not easily accessible alkaloid. His first studies on *bis*-pyridinium and *bis*-quinolinium compounds revealed the striking dependence of high activity upon the length of the chain connecting the two quaternary nitrogen atoms, but it was again among aryloxyethylamine derivatives that he found his first clinically useful drug, gallamine triethiodide (1947). Later he studied a long series of choline esters of aromatic and aliphatic dibasic acids, work which led to the discovery of the useful short-acting drug, suxamethonium iodide (1949). In all his work Bovet has not only directed, and frequently devised, the pharmacological screening tests used; but he also seems to have had an instinctive genius for deciding what chemical compounds would be most likely to have the desired pharmacological properties.

High-Altitude Rocket Experiment

The successful firing on October 22 of an American research rocket (Project Farside) to a height of several thousand miles above a Pacific atoll is an achievement of great interest to upper atmosphere research workers who cannot command the enormously expensive resources needed to launch a satellite. The rocket consists of a four-stage vehicle using available American solid-propellant rockets in clusters. The complete vehicle is carried to a height of about 100,000 ft. by a 200-ft. diameter balloon.

The balloon carries the rocket through the denser air, in which the high speed of about 17,000 miles an hour necessary to attain a height of three to four thousand miles would otherwise give rise to enormous drag forces. These would seriously reduce the altitude and produce such intense kinetic heating that the rocket would almost certainly be destroyed during the ascent. This application of the balloon has already been well illustrated by the American 'Rockoon' programme. The technique is not without its problems, however, because launching a fragile balloon carrying a rocket assembly weighing nearly a ton is a difficult task. Moreover, having ascended through the denser air, conventional stabilizing fins can no longer be relied upon to overcome the effects of rocket jet malalignment and keep the rocket pointing in the right direction. The comparative simplicity and cheapness of the design give promise of further useful measurements on cosmic rays, ion density, magnetic effects and other physical phenomena.

PLUTO : Materials Testing Reactor at Harwell

PLUTO, the latest materials testing reactor at the Atomic Energy Research Establishment, Harwell, which went into operation on October 25, was designed and built to provide the intense neutron fluxes which are now required to help advance the Authority's reactor research programme. In PLUTO the behaviour of materials and components for advanced power reactor systems will be examined under operational conditions created in experimental assemblies, or 'loops', built into tubes or 'holes' which pass within the intense radiation zone near the core of the testing reactor. At full power, PLUTO will generate a peak neutron flux of 10^{14} neutrons/cm.^{2}/sec. at a heat output of 10 mW. The reactor uses highly enriched uranium as a fuel, and heavy water as both coolant and moderator. It is similar in design to the DIDO materials testing reactor, which was formally opened at Harwell in November 1956, but there are fewer 'holes' into the core of PLUTO, since these are primarily designed for large testing 'loops'. A second reactor (DMTR—Dounreay materials testing reactor) is under construction at Dounreay.

Construction of PLUTO

THE core of PLUTO comprises a cylindrical array of twenty-six vertical boxes, each made up into a composite fuel element from ten curved uranium–aluminium alloy plates. The reactor is controlled by moving seven cadmium-sheathed 'signal arms' into the core between the fuel elements. The circulating heavy water, which is forced upwards through the fuel element assembly for cooling, is contained in an aluminium tank surrounding the core. This core tank is in turn surrounded by a graphite reflector sealed into a helium-filled steel tank and by the concrete biological shield. The heavy water is pumped through the core tank from a circuit outside the reactor: the heat generated by the system is transferred to a secondary coolant, ordinary water, in a heat exchanger in the heavy water circuit. The secondary coolant dissipates the generated heat to the atmosphere in cooling towers outside the reactor building. The whole of the reactor area is enclosed in an airtight shell with controlled entrances so that any accidental release of radioactivity can readily be confined. Eighteen tubes are mounted inside the reactor itself to serve as experimental holes: for example, four of them pass horizontally through the reactor close to the reactor core. These holes will be used for holding large-scale engineering loop systems in which fuel, canning materials, coolants, moderators and constructional materials will be tested under specific design conditions. PLUTO will also be used for producing cobalt-60 at high activity levels for hospital and industrial use. The reactor and its associated plant and buildings were designed and constructed by an Atomic Energy Research Establishment team in association with the Ministry of Works and Messrs. Head Wrightson Processes, Ltd.

The Atomic Energy Establishment at Windscale

REPLYING to questions in the House of Commons on October 29 regarding the accident at the Atomic Energy Establishment at Windscale on October 10, the Prime Minister said that the Authority received the report of the committee of inquiry, under Sir William Penney's chairmanship, on October 28, and that he would make a further and full statement early in the next session when this report had been assessed. He was also asking the Medical Research Council to give an independent view on the information collected, so far as it affects public health. Mr. Macmillan said that, with his approval, the Authority has decided that such an inquiry could best be conducted by a committee of eminent scientists with experience of nuclear energy who are unconnected with the industrial group of the Atomic Energy Authority, but at this stage he could conceive of no man with Sir William Penney's knowledge who was not directly concerned with this part of the work. The object would be to get the most rapid report by the most competent investigators; but he agreed to consider the possibility of a further inquiry under a scientific but more independent chairman, and also the possibility of publishing the report. He emphasized the Government's concern to maintain the unique reputation of British scientists in this field throughout the world.

Monitoring Radioactive Fall-out

IN a written answer in the House of Commons on October 29, the Prime Minister said that the United Kingdom Atomic Energy Authority exchanges information with the United States Atomic Energy Commission on the measurement of fall-out from nuclear weapon tests, and some of this information may be passed on to other interested government organizations in the United States. Regular measurements of strontium are taken at various places in the United Kingdom, including some in the Welsh mountains, and the evaluation of the results proceeds continuously. The Atomic Energy Authority has prepared several reports on the subject, the latest, "Radiostrontium in Soil, Grass, Milk and Bone in the United Kingdom", being dated August of this year. In an oral reply to further questions on October 31, the Prime Minister said that last summer the Agricultural Research Council accepted responsibility for monitoring soil, herbage, farm animals, and milk and other foodstuffs, while the Atomic Energy Authority will remain responsible for monitoring air and rain-water and for determining the radioactivity present in samples of human bone. The Joint Committee of the Agricultural and Medical Research Councils and the Development Commission on Biological (Non-Medical) Problems of Nuclear Physics, under Lord Rothschild's chairmanship, is responsible for oversight of this monitoring, and it has set up a special sub-committee under Dr. J. F. Loutit, director of the Medical Research Council Radiobiological Research Unit. Mr. Macmillan said that he is satisfied that it is right to proceed with the further tests at Christmas Island.

Observations on the Russian Satellite

A MEETING of the Royal Society will be held on November 29, beginning at 10.30 a.m., when Prof. H. S. W. Massey will open a discussion on "Observations of the Russian Artificial Earth Satellite and their Analysis" ; the discussion will continue throughout the day.

An additional meeting of the Radio and Telecommunication Section of the Institution of Electrical Engineers has been arranged to be held on November 22, when there will be a discussion on "Radio Observations on the Russian Satellite". A number of short contributions will be presented by members of the various establishments in Britain who have been making observations. These contributions will describe the part which radio is playing in observing the behaviour of the first satellite and the subject will be divided into the following five sections : interferometer determinations ; direction finding ; Doppler determinations ; signal characteristics ; radar determinations. The meeting will commence with an afternoon session from 2.30 to 4.30 p.m., to be followed by tea and an evening session starting at 5.30 p.m. Further information can be obtained from the Secretary, Institution of Electrical Engineers, Savoy Place, London, W.C.2.

British Computer Society, Ltd.

MORE than two hundred members attended the first meeting on October 21 of the British Computer Society, Ltd., held at the MacMillan Hall of the University of London. Prof. D. R. Hartree, under the title of "The Machine's-Eye View", gave examples of errors that can occur in computing processes. He made two points ; first, in a hand computation an intelligent and experienced computer will often exercise that intelligence, and intuition, based on experience, about the sort of way in which the calculations are likely to go ; whereas the machine is an approximation to an unintelligent and inexperienced computer, and has not got this background of knowledge and experience unless it is explicitly built into the programme. His second point was made on behalf of the machines, emphasizing that machine errors are not the only sources of wrong results. Such errors may also occur through the machine being supplied with the wrong data, through programme errors, or through use of a programme which carries out, however correctly, a process which is unsuitable for obtaining the results required. It is essential for the user of the machine to understand not only how to programme but also what to programme.

Process for Crease-fixed Wool

THE success of wool/'Terylene' fabrics in providing durable pleats in skirts and creases in trousers has revealed the large consumer demand that exists for garments with these properties. The problem of providing such stable creases is that of obtaining a permanent set in the fibres that compose the fabric. Wool can be permanently set by a number of chemical processes, and attempts have been made to use these in providing durable creases in all-wool fabrics. The difficulty has been to obtain one that was commercially attractive. The Commonwealth Scientific and Industrial Research Organization (Australia) now reports that the method based on thioglycollic acid can provide durable creases in all-wool materials. The method has the advantage of simplicity in commercial application.

University News : The Queen's University, Belfast

THE following appointments in The Queen's University of Belfast have recently been made : Dr. J. C. West, to the chair of electrical engineering : Dr. J. Pemberton, to the chair of social and preventive medicine ; Dr. L. W. Kerr, to be lecturer in physics ; Dr. I. C. Roddie and Mr. E. W. Clarke, to be lecturers in physiology ; and Dr. J. W. Dundee, to be lecturer in anaesthetics.

Announcements

AT the annual general meeting of the Association of Clinical Biochemists, held recently at the Royal College of Surgeons, London, the following officers were elected : *President*, Prof. E. J. King ; *Chairman*, Dr. R. Gaddie ; *Hon. Treasurer*, Dr. J. H. Wilkinson ; *Hon. Secretary*, Dr. A. L. Tárnoky (Royal Berkshire Hospital, Reading).

THE latest date for submission of applications for research fellowships in psychiatry, psychology, sociology, neurophysiology, and other sciences relevant to mental health, offered by the Foundations' Fund for Research in Psychiatry, is February 1, 1958. Further details may be obtained from Foundations' Fund for Research in Psychiatry, 251 Edwards Street, New Haven, 11, Connecticut.

Optica Acta and *Acta Electronica* have undertaken the joint publication of the full proceedings of the international symposium on the physical problems of colour television held in Paris last July. Inquiries can be addressed to *Optica Acta*, 3 Boulevard Pasteur, Paris 15ème, or *Acta Electronica*, 23 rue du Retrait, Paris XXe.

THE Institution of Chemical Engineers has joined the European Federation of Chemical Engineering, the object of which is "the furthering of European co-operation in the field of chemical engineering, which includes chemical apparatus and equipment, chemical process technology, materials as applied in the industry, and basic chemical operations." The European Federation of Chemical Engineering now has the following Secretariats : Deutsche Gesellschaft für Chemisches Appatewesen, in Frankfurt am Main ; the Institution of Chemical Engineers, in London ; and Société de Chimie Industrielle, in Paris.

ERRATUM. In the communication entitled "Adiabatic Piezo-Optic Coefficient of Heavy Water", by C. K. Narayanaswamy, P. S. Narayanan and R. S. Krishnan (*Nature*, 180, 497 ; 1957), the phrase ". . . carbon disulphide, a highly polar liquid" occurring near the end of column 1, p. 498, should read ". . . carbon disulphide, a highly anisotropic liquid".

THE CHEMICAL RESEARCH LABORATORY

THE annual open days of the Chemical Research Laboratory (Department of Scientific and Industrial Research) were held during October 1–4.

The Corrosion of Metals Group showed the results of research, on behalf of the British Shipbuilding Research Association, on methods of preventing pitting of mild steel tubes in Scotch marine boilers. Electrically heated model boilers were in operation, and corroded boiler tubes after test were displayed. Results were summarised in the form of curves showing the influence of various factors on the depth of pitting of the tubes. An increase in salinity or in oxygen content of the boiler water increases the rate of pitting. Even in very adverse conditions, however, the danger of serious pitting can be greatly reduced if the boiler water is kept slightly alkaline or the copper content of the mild steel tubes is more than 0·1 per cent.

Fundamental and applied investigations of corrosion inhibition in aqueous solutions were illustrated. The use of radioactive tracers has enabled a quantitative study to be made of the formation of invisible films on iron and steel immersed in solutions of corrosion inhibitors such as sodium chromate, sodium nitrite and sodium benzoate. After a short initial period of rapid adsorption, the film grows logarithmically with time of immersion, with an adsorbed film always present. The steel is passivated only if the concentration of inhibitor is maintained at a value sufficient to maintain the logarithmic growth of an oxide film, and an adsorbed layer of inhibitor on the film.

Examples were shown of the effectiveness of combinations of various inhibitors, such as sodium benzoate/sodium nitrite or triethanolamine phosphate/sodium mercaptobenzothiazole, in protecting a wide range of metals and alloys in ethylene glycol antifreeze solutions.

In chemical engineering researches a light transmission instrument has been developed for measurement of the interfacial area in gas–liquid and liquid–liquid dispersions and this instrument is being applied to the evaluation of this property in agitated vessels.

A parallel beam of light is passed down a tube immersed in the dispersion and by means of prisms is caused to pass through the dispersion and thence upward through another tube similar to the first on to a photocell. The second tube is blackened internally to remove scattered light so that only that portion of the incident light beam which meets no obstruction in the dispersion is recorded by the photocell.

The photocell is connected to an electronic integrating device so that a time-average value of interfacial area may be measured in dynamically maintained dispersions.

The two immersion tubes, light source and photocell are rigidly mounted together on a traversing platform so that interfacial areas may be evaluated near to and at various distances from the impeller in agitated vessels.

An attractive display of pure metals was seen in the Inorganic Group. The process of zone refining has been applied not only to the purification of metals but also to some non-metals like tellurium and to compounds such as indium iodide. One striking effect that was brought out was how closely many metals resemble each other in appearance when pure and when the surface oxide film has been removed. In connexion with the purity of mercury there was demonstrated the 'brightness' test according to which even traces of certain metallic impurities, of the order of 1 in 5–10 million parts, can cause a visible film to form on the surface of the mercury.

The separation of the rare earths by ion-exchange methods was demonstrated, and laboratory and semi-scale equipment for this purpose was in operation.

In the section dealing with spectrographic analysis the emphasis was on the analysis of rare-earth mixtures. The use of a four-step rotating sector to extend a limited range of standard mixtures for calibration purposes was demonstrated, and an improved water-cooled version of the gas cell, enabling high current arcs to be run in atmospheres other than air, was on view. Of interest to users of grating spectrographs was the tabulation of ultra-violet transmission limits of some sixty materials for use as order filters.

The Microanalytical Section exhibited equipment used in routine microanalysis. The 'empty tube' or rapid combustion method was being used for carbon and hydrogen, but the Carius method was preferred for halogen and sulphur. A modified Unterzaucher procedure for oxygen was also shown.

New adsorbents and ion-exchange materials for specific purposes were shown by the Radiochemical Group. A typical example was phosphorylated cellulose obtained by treating cellulose with urea and phosphoric acid. This material exhibits cation-exchange properties. The ion-exchange properties of phosphorylated cellulose differ from those of more conventional resins in that certain metals (particularly Th^{4+}, Zr^{4+}, U^{4+}, Ti^{4+}, Ce^{4+}, Fe^{3+} and UO_2^{2+}) are adsorbed from strongly acidic solutions (up to 5 *N*). The adsorbed metal can only be eluted with reagents which strongly complex with it, for example, ammonium carbonate for thorium and acetone—hydrochloric acid for iron. This property of phosphorylated cellulose has been applied to the selective recovery of thorium from monazite. Work has continued on solvent extraction as an alternative to ion-exchange for the selective concentration of uranium and other metals from leach liquors. Solvent extraction offers the advantage of continuous counter-current operation, greater flexibility in coping with changes in feed composition, and freedom from mechanical blockage and chemical poisoning which occur in ion-exchange. Against this must be reckoned the loss of solvent to the aqueous phase which represents the chief factor controlling the operating cost of solvent extraction.

Two main types of solvent are used, namely, acidic and basic; the former may be considered as analogous to cation-exchange resins, the latter as analogous to anion-exchange resins; basic solvents are more selective for uranium. Acidic extractants include the long-chain mono- and di-alkyl phosphates, while basic extractants include the many types of high molecular weight amines.

An apparatus for the measurement of low-pressure deviations from the ideal gas laws in the temperature-range of 50–200° C. was shown by the Organic Group; the apparatus is suitable for the study of those organic compounds which have a vapour pressure of at least 200 mm. in that temperature-range. Also shown was an apparatus, still under construction, which has been designed for the precise determination of the latent heats of vaporization of organic liquids, and for the measurement of the specific heats (at constant pressure) of organic vapours; the working temperature-range for this apparatus is likewise 50–200° C.

Of the new developments shown in organic intermediates, the following were of particular interest: a novel method of carboxylation based on the use of sodium ethyl carbonate; the carboxylation of chrysene and pyridine through their sodio-derivatives; the synthesis of a variety of polymeric materials containing the hydrazino group. Particularly noteworthy was the use of N-amino oxazolid-2-one as a source of N-amino ethyleneimine and its polymer, polyethylene hydrazine; the synthesis of arsenic-containing polymers from arsenic pentoxide and epoxides, and the trimerization of aromatic isocyanates in solution in various epoxides by a trace of pyridine.

There is at present considerable interest in the use of electrodialysis for the removal of salt from sea water, or from brackish waters, which are unfit for drinking or irrigation purposes. Successful application of this process depends on the efficiency of the ion-exchange membranes in multi-compartment electrolytic cells. In the High Polymers Group, methods for the preparation of ion-exchange membranes are being investigated, and a study is being made of their electrochemical properties. Membranes prepared by incorporating particles of an ion-exchange resin in an inert binder may contain void spaces which can lead to inferior electrochemical behaviour. Emphasis has therefore been placed on the preparation of homogeneous ion-exchange membranes, and promising cation- and anion-exchange membranes of this type have been prepared.

The possibilities of paper strip chromatography for the analysis of polymers are also being studied in an attempt to find a simple routine procedure for evaluating molecular weight distributions. A synthetic polypeptide (polysarcosine dimethylamide) served as a convenient model polymer since it can be prepared with very sharp molecular weight distributions. Mixed samples of polysarcosines of molecular weights up to 12,000 have been successfully fractionated on paper strips. The best results were obtained by gradient elution, that is, pumping a good solvent steadily into a reservoir of poor solvent from which ascending development took place. In most cases a polymer labelled with carbon-14 was used for assessing the chromatograms.

The Microbiology Group made a feature of the economic and industrial importance of bacteria taking part in the natural sulphur cycle. Various exhibits explained the activities of these bacteria in polluting aviation fuel oils and coal gas, their function in the disintegration of concrete and in the corrosion of buried metals, and the microbial formation of sulphur in Nature. Of special interest was a process, devised at Teddington and now being developed by the London County Council, for producing sulphur from sewage sludge and gypsum by a semi-continuous fermentation. Continuous techniques, which may well constitute the next important technological advance in the fermentation industries, were also illustrated, and included a novel adaptation of the conventional bubble-cap distillation column. The National Collection of Industrial Bacteria displayed its comprehensive range of assay organisms, which are extensively used by industrial and other research workers for estimating various amino-acids, vitamins and antibiotics.

INTERNATIONAL COLLOQUIUM ON INTERFERENCE SPECTROSCOPY

THIS colloquium, organized by the Centre National de la Recherche Scientifique, was held at Bellevue, near Paris, during September 9–13.

Interferometric spectroscopy might appear a rather narrow field for an international conference extending over five days. In fact, the organizer, Prof. P. Jacquinot, proved to be wise in imposing a restriction which went as far as excluding diffraction gratings, when used by themselves, as too conventional: there was ample variety, not only of details but also of fundamentally new and interesting approaches. The number of talks and the size of the audience could be kept in reasonable bounds, allowing worth-while discussions to develop. The proceedings of this most stimulating conference are to be published in the *Journal de Physique* and should well represent the main lines of the recent advances in this field. Methods, rather than results, formed the subject of the conference.

Interferometers have a fundamental advantage compared with gratings or prisms, in a way which has been most clearly expressed by Jacquinot in the form of a coefficient of merit. In the latter instruments the path difference depends strongly on the angle, a fact which necessitates the use of a slit. This restriction of area in the plane of the slit, or of angle in the collimated beam, entails loss of light gathered. In contrast to this, interferometers use interference 'in depth', with path differences depending on the angle only to the second power, as shown in the axial symmetry of interference patterns. By imaging an extended source in the plane of an interference pattern rather than on a narrow slit or slit-image, one can gather more light from it.

Full advantage of this can be taken in recording methods where a circular stop is placed in the centre of the fringe pattern, followed by a detector, such as a photo-multiplier. While the path difference is varied at a uniform rate, for example, by variation of the air pressure, the intensity is recorded. This method has lately been increasingly used, and various ways of changing the path difference were described at the conference (R. Chabbal and M. Soulet, J. H. Jaffe, J. Gobert, J. Roig, R. Dupeyrat); besides an alternative method in which the intensity is recorded directly against the air pressure, without a time base (H. G. Kuhn and J. L. Lucas-Tooth).

The quantum efficiency of photocells is generally higher than that of photographic plates, but while the latter collect energy of all wave-lengths simultaneously during the whole time of the exposure, in the recording technique different wave-lengths act successively, each only for a fraction of the total time of recording. This waste of energy can be avoided by methods which are grouped together by such names as 'Fourier transform method' or 'multi-channel spectroscopy'. Their principle goes back to Michelson's interferometric analysis by 'visibility curves'. We imagine the intensity in the centre of the fringe system, produced by a Michelson or other two-beam interferometer, to be recorded while the path difference is changed at a uniform rate, for example by translational motion of one of the reflectors. If the incident light is monochromatic, a pure sine curve will be recorded, and for any arbitrary spectral distribution the record obtained will be a Fourier transform of the spectrum. In principle, and with certain restrictions which need not be mentioned here, this record can be transformed back into the original spectrum by numerical calculation, or by the use of computers. In actual fact, the primary spectrum has to be limited to a small spectral range, and certain information on the spectrum usually has to be assumed beforehand. Instead of the absolute wave-numbers, differences against a reference wave-number are often measured.

The difficulty of making the motion exactly uniform, and the small path difference obtainable in practice, limit the method to low resolving powers and mainly to the infra-red. In this spectral range, on the other hand, the gain in light-gathering power which this method achieves is most valuable: because of the photon noise in the receiver, the resolving power obtainable is often limited by the intensity. This applies particularly to astrophysical measurements for which the method offers considerable promise. A number of speakers discussed the principle of the method and described actual devices putting it into practice (P. Fellgett, G. A. Vanasse, J. and P. Connes, E. Ingelstam, P. Jacquinot, H. A. Gebbie, L. Merz).

A most unorthodox system was described by P. Connes, who uses two plane gratings to form an interferometer; they take the place of the reflectors in a Michelson interferometer and are slowly and synchronously rotated. At any given moment, light of that wave-length for which the incident and reflected wave-fronts are parallel is modulated by a longitudinal displacement of one of the gratings—in practice achieved by a to- and fro- rotation of the compensator. The device acts as a grating used with direct recording, but the absence of a slit ensures the gain in intensity characteristic of interferometers.

P. Connes also described the construction and the first successful experiments with his ingenious 'spherical Fabry–Perot interferometer'. Between the partially reflecting, spherical surfaces the wave suffers four successive reflexions before it interferes with the direct wave, as compared with the two reflexions in the plane Fabry–Perot. The path difference is independent of the angle not only to the first power of small angles as in the ordinary etalon, but even to the second. This allows a greater solid angle to be used in recording, with a resulting gain in intensity. The instrument offers considerable advantages when very large path differences are required, and the adjustment is extremely easy. The spacing cannot, of course, be varied, and this will restrict the use of the instrument to special purposes.

The use of multiple dielectric films as coatings for étalon plates were treated by F. A. Jenkins, P. Giacomo, A. Steudel, R. Lennuier, J. Ring, R. Dupeyrat and F. Abelès. Two recent advances in this field will make dielectric coatings much more attractive to spectroscopists than they have been hitherto: the width of the reflexion band can now be made large enough to cover an appreciable portion of the visible spectrum, and films can be made for use in the ultra-violet down to 2500 A.

Photographic interferometry, as a well-established method, very naturally played a smaller part at the conference. Any idea that it has now been superseded by recording methods and had become obsolete would be quite mistaken. Its great power of integrating and of simultaneously recording a large range of the spectrum will ensure its retention, and it is often preferable when wave-numbers rather than intensities are to be measured accurately. Contributions on precision measurements with a double étalon (D. A. Jackson) and on solar interferometry (P. J. Treanor) served as useful reminders of these facts.

Metrological applications, designs of special interferometers and various other topics were discussed. These have to be omitted from this report not for their lack of importance but for reasons of brevity and because they cannot easily be grouped together.

H. G. KUHN

INTERNATIONAL UNION OF CRYSTALLOGRAPHY

CONGRESS IN MONTREAL

THE International Union of Crystallography held its fourth General Assembly and International Congress in Montreal, during July 10–17. About six hundred crystallographers from nineteen countries attended, accompanied by about one hundred and fifty wives (or husbands) and children. The Congress was followed by two symposia held during July 17–19. A full programme of social events and excursions of scenic and technical interest was arranged, and first-class facilities were provided by McGill University. During the evening spent at the Université de Montréal the retiring president, R. W. G. Wyckoff, spoke on "Electron Microscope Studies of Macromolecules", with beautiful photographic illustrations.

In the report on the meetings of the International Union of Crystallography held in Madrid in 1956 [1], it was commented that the arrangement of several simultaneous sessions was unsatisfactory, and that a number of small meetings, more restricted in scope and with a single subject only claiming attention at any one time, would be more valuable. This difficulty of fragmentation had been felt by the organizers of the Montreal Congress, and a number of general lectures were arranged on several mornings at a time when there was no competition from other meetings. These formed a valuable feature of the Congress, and provided a painless method for specialists in other branches to become acquainted with the present state of crystallography of proteins (D. Hodgkin), crystal chemistry (G. S. Ždanov), interatomic distances and molecular configurations (D. G. Jenkins, J. S. Taylor and L. E. Sutton, presented by L. E. Sutton), clay minerals (G. W. Brindley), and imperfect structures (P. B. Hirsch). In most of these fields there was steady progress but no striking new developments to report. Prof. G. S. Ždanov presented some unusual views on crystal chemistry, and publication of his talk will be awaited with interest. Among the imperfect structures, the most interesting development was in methods for the direct observation of dislocations in crystals. It has been found possible to 'decorate' dislocations in such crystals as silver bromide and silicon with foreign atoms, thus making possible stereoscopic electron micrographs in which the dislocation network could be clearly seen. By a different technique of transmission electron microscopy, it has been possible to make motion pictures of dislocations in thin metal foils, showing pile-ups, networks, splitting of dislocations to form stacking faults, and the interaction of dislocations with boundaries.

The technical scientific papers were arranged in seventeen sections, of which four or five were generally meeting simultaneously. There was, therefore, little relief from the overcrowding experienced in Paris[2] and Madrid[1]. It is clearly impossible to detail the proceedings of all the sections, but a few of the more important features may be mentioned. In the Section on apparatus and technique, developments in the use of high-speed electronic computers were perhaps the most interesting. Methods for the accurate measurement of integrated intensities, the basic requirement for all structure work, were also described. The section on structure determination reported progress in phase-determination by several methods, but there seems to have been nothing as striking as the first impact of sign relations[2]. Minerals, clay minerals, and metals yielded a considerable number of new structures; the increasing complexity of structures of metals is noteworthy. Aside from numerous monoclinic alloys, elemental plutonium is monoclinic, with 16 atoms per cell and a co-ordination number of about 14. Complex oxides were perhaps the most interesting of the new inorganic structures; ribonuclease and viruses claimed attention in the Section devoted to the proteins and related compounds—which ranged from glycine to hæmoglobin. The Section on order–disorder phenomena and deformations and imperfections formed a rather artificial division of an active field. The 'spikes' in the reciprocal lattice of some diamonds and the distribution of intensity in reciprocal space corresponding to crystals with mistakes are still not completely understood. Disorder phenomena (in cobalticyanides, for example) were also reported in other sections. Crystal growth was perhaps remarkable in that little mention was made of dislocations. Neutron diffraction provided information about structures not easily obtained by X-ray means, including the location of hydrogen nuclei in hydrogen bonds.

Two Commissions of the International Union, on data and teaching respectively, held open meetings virtually amounting to additional sections. In the meeting of the Teaching Commission, H. Lipson showed the importance of Fourier transforms, especially those produced with such ease by optical means, as a teaching method. Other papers discussed band groups (A. Pabst), and crystal growing (R. Kiriyama) as student exercises, and the lessons to be gained from a study of the historical development of our knowledge of zeolites (R. Hocart). The Data Commission was chiefly concerned with possible improvements, both in the data themselves and in methods of their use, in the "X-ray Powder Data File", though single-crystal and electron-diffraction data were not quite forgotten.

Both the Apparatus and the Teaching Commissions organized non-commercial exhibitions. In addition, there were many exhibits of X-ray generators, cameras, diffractometers and other equipment available commercially, some exhibits of apparatus and techniques from university and government laboratories, and a stand of crystallographic books on show.

The symposia were concerned with physical techniques and electron diffraction. Much attention was paid to nuclear magnetic resonance, on which an introductory lecture was contributed by C. J. Gorter. Like neutron diffraction, this technique provides a method of locating the hydrogen nuclei in crystals. There were also one or two papers on dielectric and diamagnetic measurements. The symposium on electron diffraction was one of the most interesting parts of the Congress, and one in which much progress was reported, but there seem to be outstanding problems in relating diffraction intensities with structure. The contributions from Russian and Japanese members of the Congress were particularly noteworthy.

Much of the time of the business sessions was taken up with the discussion and adoption of a new set of statutes and by-laws. A new Commission on Electron Diffraction was set up, and the membership of the Commission of Crystallographic Nomenclature was severely pruned—possibly indicating changes in the emphasis on these fields. Preparations were made for holding the next Congress and General Assembly in Cambridge in 1960, and for the celebration of the fiftieth anniversary of the discovery of X-ray diffraction in Munich in 1962. A new publication of the International Union of Crystallography, reporting apparatus and techniques, was projected, but it is not yet certain whether this will be found practicable. J. Wyart (Paris) was elected president of the Union for the period to the next General Assembly.

RHEOLOGY OF DISPERSE SYSTEMS

RHEOLOGISTS from Holland, Germany, Israel, Canada and New Zealand were among nearly a hundred who met during September 19–21 to discuss the flow properties of dispersions at the Annual Conference of the British Society of Rheology, held this year in the University College of Swansea.

In his presidential address to the Society, under the title "Complicated Rheological Properties", Prof. J. G. Oldroyd developed the thesis that even the simplest dispersions cannot, from their very nature, exhibit anything like simple rheological behaviour. Any system in which one component has viscosity and another has some degree of elasticity of shape must show a combination of viscous and elastic effects when subjected to a variable shear stress; this must apply whether the system as a whole is solid or fluid. Precise calculations have been made of the type of the response to small variable shear stresses to be expected in disperse systems containing two components, at infinite dilution of one component in the other, in terms of arbitrary elastico-viscous or visco-elastic properties at small shear stresses assumed for the two components separately. Even a simple emulsion of one Newtonian liquid in another, the two liquids being immiscible with a constant interfacial tension between them—physically the simplest dispersion of all—is necessarily elastico-viscous and is characterized by a single relaxation time and a single retardation time in addition to a viscosity constant. The restoring force providing the elasticity of shape is in this case the interfacial tension.

Turning to the more general flow of a liquid dispersion with rates of strain not necessarily small, Prof. Oldroyd showed that the equations of state of any system which at small rates is elastico-viscous cannot possibly be linear in the stresses and velocity gradients. No equations in which product terms are entirely absent could possibly be physically significant as equations of state of general validity, since linear equations, of necessity, imply modes of behaviour dependent on the (physically irrelevant) relative motion of the material and the co-ordinate system one happens to be using. It follows that even the simplest liquid disperse systems must be expected to show cross-viscosity effects—in particular, normal stresses, different in different directions, are called into play by a steady simple shearing motion at a finite rate. Associated with these effects are the Weissenberg climbing effects, in a positive or negative sense, or the variation of the viscosity with the rate of shear in steady shearing flow, or both these features.

The idealized systems which the applied mathematician finds amenable to exact theoretical analysis are necessarily some of the most difficult in which to detect non-Newtonian behaviour experimentally, because of the small magnitude of the predicted departures from Newtonian flow at small concentrations of the disperse phase. Prof. Oldroyd submitted, however, that real suspensions and emulsions could scarcely be expected to be simpler in their rheological behaviour than the mathematician's idealized models, so that all the above-mentioned non-Newtonian effects should be looked for in real dispersions; there, they will not always be small. Some of the experimental papers which followed bore out this contention that real dispersions have, indeed, complicated rheological properties.

Recent careful experimental work on dilute suspensions of solid and liquid spheres in golden syrup and other liquids was described by Dr. S. G. Mason (Pulp and Paper Research Institute of Canada, and McGill University). The motion of individual suspended particles and the internal circulation in suspended droplets have been observed under the microscope at the same time as viscosity measurements were being made in a Couette instrument. Evidence for the existence of a visco-elastic film of emulsifier at the interfaces in an emulsion has been collected by Dr. Mason, W. Bartok and M. A. Nawab, from both viscosity and internal circulation measurements; the results are in good agreement with the theoretical formulæ of Einstein, Taylor and Oldroyd, and there is a clear gradation of the skin effects with concentration of emulsifier. A study has been made of the change of shape of droplets at finite rates of shear and of the formation of doublets—complications usually ignored in theoretical treatments.

Dr. R. L. Whitmore (University of Nottingham) directed attention to some quite unexpected effects in the flow of a suspension in a narrow tube. The average speed of travel of the suspended particles exceeds the average speed of travel of the suspension as a whole, whenever the radii of the typical particle and of the tube are comparable. There is a theoretical explanation of this, and decisive experimental confirmation, the volume concentration of the disperse component being slightly less in a tube than in two reservoirs connected by the tube. Such phenomena call for great caution when one is obtaining samples of a suspension, for example, by means of a pipette; and give rise to apparent wall-slip, since the apparent viscosities observed in capillary viscometers of different diameters are slightly different in consequence, and different from the viscosity of the suspension as observed in a Couette instrument.

Carefully graded sizes of 'Perspex' spheres (in the overall range of diameters 40–435μ) suspended in a liquid of the same density have been used in a series of experiments described by Dr. G. F. Eveson (University of Birmingham). These experiments give some support to the rule that one can calculate the viscosity by a repeated application of Einstein's law, when two distinct, sharply sized fractions are present, the larger spheres being effectively suspended in a homogeneous liquid, rheologically equivalent to the finer particles in the pure liquid. The disturbing effect of particle interactions was apparent when the average distance between sphere surfaces was less than three-quarters of the mean diameter of the suspended spheres.

A descriptive theory of the flow of suspensions in terms of vorticity, energy and action was put forward by Dr. T. V. Starkey (Technical College of Monmouthshire). As one might expect from a largely dimensional argument, the results differed from accepted theory in respect of the numerical constants, for example, the specific viscosity of an idealized suspension is obtained as three-fifths of the correct Einstein value.

Disperse systems with the consistency of thick pastes were discussed by a number of other speakers. Dilatant and thixotropic pastes were demonstrated in films shown by Dr. A. Jobling (University of Cambridge) and J. E. Roberts (Ministry of Supply), the technique used being that of deforming samples by spreading them on a rubber sheet the change of shape of which can be carefully controlled. The appearance of periodic cracks and their subsequent disappearance on relaxation of the material by vibration are somewhat analogous to certain phenomena observed in metals. The Weissenberg effect in the negative sense can be observed in certain materials of this kind, as was also demonstrated in some pigment-plasticizer pastes by E. Bantoft (Imperial Chemical Industries, Leathercloth Division). In these, marked non-Newtonian flow was observed in shearing, possibly with a finite yield value. Thixotropy, dilatancy and the very marked elastic 'solid' response to suddenly applied stresses were observed, and explained in terms of the flocculation of particles. Somewhat similar results for pigment-oil suspensions of the printing-ink type were described by N. Casson (Imperial Chemical Industries, Dyestuffs Division).

Different viscosity measurements arising from non-Newtonian flow, as given by different commercial viscometers, were illustrated by the results of E. H. Steiner (British Food Manufacturers Research Association). In molten chocolate, a complex dispersion of cocoa particles, milk and other fats, liquid cocoa butter, sugar, etc., rheological properties are sensitive to fat content, size of particles, size distribution, heat treatment, temperature, and moisture content. Some starch–clay coating mixes, as described by R. S. Lenk (Bowaters Development and Research, Ltd.), are equally complicated, and sensitive particularly to the content of amylose. The yield-values and apparent viscosities of lutings used for water-proofing screw-threads—for example, a dispersion of synthetic wax in polyisobutene of low molecular weight—have been measured by W. A. Dukes (Ministry of Supply) in the parallel-plate, torsional and cylinder plastometers, with results which are not easy to analyse.

A novel departure from the conventional dispersion was demonstrated by T. C. Daniels (University College of Swansea), who described experiments on the fall of metal spheres of different sizes and densities through fluidized beds of sand, ilmenite, and similar powders. Such a bed is not a single, physically well-defined piece of matter but consists of a 'framework' of dispersed particles with the continuous component (air) in appreciable linear motion relative to this framework. The usually neglected migration effects (sedimentation, creaming, etc.) are here of great importance. Anisotropy is to be expected because of the privileged direction of the air flow. Experimental results lead to an empirical law that the terminal velocity of fall of a sphere through the bed is a constant plus a term proportional to diameter squared and to a power (somewhat greater than unity) of the density difference. Such a clear departure from Stokes's law deserves the interest of theoreticians. The experimental work is to continue with an investigation of the viscosity appropriate to shearing between vertical cylinders.

Informal evening discussions in the recently opened men's hall of residence, Neuadd Gilbertson, included one at some length on the subject of rheological nomenclature, to which much thought had been given by the Dutch rheologists. A free exchange of widely divergent views, under the chairmanship of Dr. G. W. Scott Blair, brought into relief, if nothing else, the many different scientific disciplines—physics, biology, engineering, chemistry, mathematics—which are brought together in the membership of the British Society of Rheology for the study of deformation and flow.

HIGH POLYMER, COLLOID AND SURFACE CHEMISTRY

UNDER the auspices of the South Australian Branch of the Royal Australian Chemical Institute, a discussion meeting on "High Polymer, Colloid and Surface Chemistry" was held during August 19–21 in the Department of Physical and Inorganic Chemistry at the University of Adelaide. The meeting was arranged by the Theoretical Chemistry Group, which has felt for some time that, because of the isolation due to the large distances between centres of research in Australia, there exists a great need to bring together members working in related fields of chemistry so that current problems can be discussed.

More than seventy members and visitors attended, including forty visitors from other States of the Commonwealth, and twenty-nine papers were presented during the three-day meeting. These were classified under the general headings: surface chemistry; synthetic high polymers; and polyelectrolytes and natural high polymers. The session opened with a series of papers dealing with the measurement and interpretation of surface phenomena.

The first paper, by Prof. A. E. Alexander (University of Sydney), outlined the methods employed in studying the relation between surface mechanical properties and chemical constitution of linear polymers. Prof. Alexander reported on a recent examination of isotactic and atactic polypropylene oxide at the oil/water interface. The necessity for further study at lower surface pressures was stressed. Some aspects of the surface properties of co-polymers consisting of styrene with very small amounts of vinyl pyridine were discussed.

Dr. C. S. Hocking (Imperial Chemical Industries, Australia and New Zealand, Melbourne) described some investigations by himself and Miss G. M. Parkins into the effect of changes in the degree of hydrolysis and molecular weight of polyvinyl alcohols on surface properties. A series of commercial polyvinyl alcohols, varying from 73–98 per cent hydrolysed, had been examined.

The use of ultra-violet absorption spectra in determining critical micelle concentrations of solutions of alkyl pyridinium iodides in water and organic solvents was reported by Dr. J. A. Friend (University of Tasmania). Above the critical concentration of micelles in water new absorption bands appear and are considered to be due to the iodide/pyridinium association. There was much discussion concerning the manner in which the iodide ions are associated.

A paper by D. A. Haydon and J. N. Phillips on the adsorption of detergents on oil drops and their charge/potential relationship was read by Dr. Phillips (Commonwealth Scientific and Industrial Research Organization, Canberra). His results confirmed that the theoretical form of the Gibbs equation is applicable to the adsorption of surface-active electrolytes in the absence of an additional electrolyte. The adsorbed ions obey the equation of state for an ideal charged monolayer. No simple relation was found between the surface and zeta potentials.

In a paper by J. N. Phillips and N. A. Walker (Commonwealth Scientific and Industrial Research Organization, Canberra) on the effect of detergents on *Nitella* cells, Mr. Walker showed evidence which suggests that the site of attack of solutions of both cationic and anionic detergents on cells of the green alga *Nitella* is the cytoplasmic outer membrane. The time required for death of cells to occur was studied. The relative effects of detergents and of changes in salt concentration indicate that adsorption on a negatively charged surface is involved. Adsorption of the detergent on the cell wall has been investigated.

Dr. B. S. Harrap (Commonwealth Scientific and Industrial Research Organization Wool Textile Research) presented the results of a study of the surface properties of soluble derivatives of wool keratin. Surface properties of the dye 'orange II' were described and also the influence of *p*H and ionic strength on the interaction of the dye with monolayers of a partially fractionated soluble derivative of wool keratin. At low ionic strength, interaction is probably by ionic bonding between dye anions and positively charged protein side-chains below the interface. At high ionic strengths, penetration of the monolayer by the dye is apparent. This is due to a change in the state of the dye adsorbed at the interface.

Surface films of gluten have been investigated, and surface pressure, compressibility, viscosity and rigidity at both air/water and oil/water interfaces have been measured. Mr. N. W. Tschoegl (Bread Research Institute of Australia) pointed out that the decision to use the techniques of surface chemistry was dictated largely by their cheapness. The systems studied were solutions of gluten in hydrochloric acid, sodium salicylate and mixtures of hydrochloric acid in ethylene chlorhydrin.

The adsorption of high polymers on solids was reviewed by G. E. Neu (New South Wales University of Technology), who pointed out that very little work had been done on the subject. Mr. Neu reported that the system polyvinyl acetate/carbon black/benzene is being investigated in Sydney, where the amount of polymer in the solvent is estimated by means of measurements of surface pressure.

Dr. B. D. Cuming (Commonwealth Scientific and Industrial Research Organization, Melbourne) discussed the adsorption of amphipathic ions on an ionic solid. The theory proposed by Held (1935) has been shown to account for the re-wetting of the surface at high concentrations. Measurements of adsorption of sodium dodecyl sulphate on barium sulphate and the effect of potential-determining and other ions are supported by the double-layer theory.

The rate of desorption of radioactive stearic acid, deposited by the Langmuir–Blodgett technique on single and polycrystalline silver surfaces, have been measured by Geiger-counter and autoradiographic techniques. J. A. Spink (Commonwealth Scientific and Industrial Research Organization, Melbourne) described experiments which show that the forces by which long-chain polar molecules are attached to solid surfaces depend upon the crystal orientation of the substrate. Since desorption rates have also been found to be influenced by the state of surface, it was necessary to standardize the method of surface preparation.

The first two papers on the second day were concerned with kinetic studies. In the first, Dr. A. Parts (University of Sydney) presented some results on the kinetics of polymerization of acrylonitrile in water in the presence of hydrogen peroxide and ferric salts. The reaction was found to be second order with respect to the dissolved monomer. The rate increases with increasing concentrations of hydrogen peroxide and iron salt, but decreases with increased concentration of hydrogen ions. The degree of polymerization was found to increase with increasing concentration of monomer and hydrogen ions, but to decrease with increasing concentration of hydrogen peroxide and ferric salt. Possible mechanisms were discussed, but the complete picture remains obscure.

In the second paper some recent work on the polymerization of styrene in solution in carbon tetrachloride and catalysed by aluminium chloride was reported by F. E. Treloar (University of Adelaide), who stated that intensive drying of reagents failed to stop polymerization. However, the bright colours attending the reaction indicate that the last trace of water was not completely eliminated. The rate of polymerization was shown to be second order with respect to the monomer and first order with respect to the catalyst.

The two papers on kinetics were followed by a group of three papers dealing with synthetic problems concerning block and graft co-polymers. Presenting the first of these papers by W. G. P. Robertson and J. M. Hammond, Mr. Hammond (Weapons Research Establishment, South Australia) described several methods attempted in the synthesis of polymers consisting of a polyisobutene backbone bearing branches of polymethyl acrylate. The most successful involved conversion of the hydrocarbon polymer to a photochemical polyinitiator by photobromination, followed by branch-growth polymerization of methyl acrylate. The graft polymers formed display odd behaviour in solution due to the marked difference in nature between the backbone and the branches of the molecules. Kinetic study was hampered by troubles with solubility, but it was obvious that the kinetics of the system are more complicated than might be expected.

Two new methods for preparing block co-polymer were presented by Dr. J. R. Urwin (University of Adelaide). In the first case, polystyrene containing cumenyl end-groups was prepared by polymerizing styrene in the presence of cumenyl mercaptan. The polystyrene was oxidized and the product used in an emulsion-type polymerization of methyl methacrylate. In the second case, the dihydroperoxide of cyclohexanone was used in an emulsion polymerization to produce polystyrene, which was then employed as an initiator in the bulk polymerization of methyl methacrylate. The polymers were shown to contain block copolymer by comparing the turbidimetric titration of the block with simple mixtures of the parent polymers.

The third paper, presented by D. H. Solomon (Balm Paints, Sydney), described how the application of concepts of polymeric structures of block or graft type were contributing to the evolution of improved surface coatings. Blends of alkyds, drying oils, vinyl monomers with epoxy and urea formaldehyde resins have shown that some of the resulting three-dimensional structures with long-range periodicities offer outstanding combinations of desirable properties.

Of technological interest also was the next paper, on the cross-linking efficiency of monomers in polyester resins, by W. G. P. Robertson and D. J. Shepherd (Weapons Research Establishment, South Australia). In the paper, read by Dr. Robertson, the physical properties of resins prepared from the same unsaturated polyester with different monomers were compared. Some correlation was found between resin properties and calculations of degree of cross-linking based on the known behaviour of the monomers co-polymerized with fumarate esters.

Dr. J. V. Sanders (Commonwealth Scientific and Industrial Research Organization, Melbourne) read a paper by himself and R. G. Sherwood on the thermodynamics of mixtures of silicones and benzene. Measurements have been made of the vapour pressures of these mixtures over the complete range of concentrations. Results were compared with calculations made using the 'cell' theory of liquids and the agreement was found to be satisfactory. Three samples of silicones available commercially, with the usual spread of molecular weights, were used in these experiments.

In a study of second-order transitions in non-crystalline high polymers Dr. H. A. J. Battaerd (Imperial Chemical Industries, Australia and New Zealand, Melbourne) presented the results of a study of apparent second-order transitions in the system polyvinyl chloride/dioctyl phthalate, made by following the dependence of refractive index on temperature. A number of transitions were found, suggesting various stages in the plasticization.

I. Endzins (Hilton Hosiery, Ltd., Victoria) described the fractionation of three commercial acetate rayons in the system phenol/cyclohexane. The mass, frequency and integral distribution curves were determined. The relations between these distributions and such properties of the fibres as acid content, swelling and absorption of moisture were discussed.

The final day was devoted to discussion of polyelectrolytes and natural high polymers. The first two papers concerned properties of solutions of polyelectrolytes, and then a series of papers on natural high polymers was read. Studies of viscosity, conductance and streaming birefringence in aqueous solutions of poly-4-vinyl pyridonium chloride were presented by T. Kurucsev (University of Adelaide). The dependence upon concentration of these physical properties was found to be discontinuous at very low concentrations, and an interpretation of this behaviour was presented in terms of the reversible aggregation of the polyelectrolyte molecules. The possible forces involved in the formation of aggregates were discussed.

Experiments designed to measure the charge on polyelectrolytes in solution were described by J. E. A. Gooden (University of Adelaide). It was reported that measurements of conductivity and of transport properties on polymethacrylate ions showed a decrease in charge with an increase of bound counterions. Sodium deoxyribonucleic acid shows the opposite trend. It was suggested that a composite curve of these results might in fact represent a general phenomenon.

The denaturation of proteins by the action of urea was reviewed by Dr. H. A. McKenzie (Commonwealth Scientific and Industrial Research Organization, Sydney). The results of experiments on a series of proteins in the presence of 7 M urea were discussed in terms of a denaturation process and aggregation. Measurements of sedimentation, diffusion and viscosity had been used for determining denaturation and optical rotation to detect aggregation. Dr. McKenzie reported the effects of pH on these measurements, and cautioned against drawing conclusions at a particular range of pH, since in some cases reaction is slow and therefore the measurements are dependent upon time.

The interaction of whole serum with water-soluble amides and triazoles in relatively dilute solutions was reviewed by Prof. J. B. Polya (University of Tasmania). The main features of extensive electrophoretic studies were presented in some detail. The effects of time, pH and protein concentration were reported, together with preliminary viscosity data. Prof. Polya presented an interpretation of these observations and discussed some applications.

The properties of α-keratose and S-carboxymethyl kerateine-2 have been studied by sedimentation, viscosity and light-scattering methods by E. F. Woods (Commonwealth Scientific and Industrial Research Organization, Melbourne). It was shown that in aqueous buffer systems the molecular parameters determined by these methods are dependent on time, temperature, salt concentrations, pH, and time and speed of centrifuging. The influence of disaggregating agents has also been studied. The most effective were 8 M urea, sodium dodecyl sulphate, 10 M acetic acid and $N/10$ alkali.

Dr. J. M. Creeth (University of Adelaide) read a paper by himself, L. W. Nichol and D. J. Winzor on electrophoretic fractionation of the albumin component of egg white and the characterization of original and fractionated material by means of measurements of Rayleigh diffusion. The two components apparently had identical coefficients of diffusion. This lends some support to the hypothesis that the only difference between the components lies in their content of phosphate.

A paper by L. G. Ericson and S. G. Tomlin (University of Adelaide) on the study of collagen by means of low-angle X-ray diffraction techniques was read by Dr. Tomlin. This work was designed to give evidence about details of organization in the size-range of, say, 10–1000 A.—and thus provide information about the arrangements of large molecules in fibrous structures. Attempts to solve the problem of the interpretation of these diffraction patterns by the incorporation of heavy atoms into collagen fibres have been made using the complementary techniques of X-ray diffraction and electron-microscopy. In this way it has been possible to locate heavy atoms in the fibres, and a preliminary account of these findings was presented to the meeting.

In a paper on the sedimentation of nucleic acid solutions, J. H. Coates (University of Adelaide) described experiments which indicate that the very sharp sedimentation boundaries exhibited by solutions of sodium deoxyribonucleate in the ultracentrifuge are related to a change in the charge on the nucleate ion across the boundary. Mr. Coates considered that this explanation is in closer agreement with experimental results than the hypothesis of the dependence of the sedimentation coefficient upon concentration.

R. B. Inman (University of Adelaide) described some results from measurements of conductivity and transport made on salt-free deoxyribonucleic acid. Derived values, such as the charge and mobility of the polyion kinetic unit, were reported at the meeting, and it was suggested that the observed change of properties with concentration results from a reversible equilibrium between single molecules and aggregates.

The isolation of tobacco mosaic virus in various states of aggregation was reported by J. N. Phillips and M. Zaitlin (Commonwealth Scientific and Industrial Research Organization, Melbourne). Preparations of two strains of purified tobacco mosaic virus subjected to continuous electrophoresis on filter paper have been separated into a number of fractions. These fractions were examined by light scattering, by ultra-violet spectrophotometry and in the electron microscope. In the one case (U_2) little difference was observed between the fractions, whereas in the other there was a progressive variation in the content of nucleic acid and in average molecular weight. Furthermore, the distribution of particle sizes throughout the U_1 fractions indicated the virus rods were split in a non-random fashion on the paper. These observations were discussed with reference to the different physical behaviour of the two strains in the light of the current conception of the structure of the tobacco mosaic virus.

That the meeting afforded those who attended a welcome opportunity to meet others working in related fields and to discuss current research problems was evidenced by the enthusiasm with which the papers were received and the lively discussion and comment they aroused.

W. G. P. Robertson
J. R. Urwin

BRITISH RUBBER PRODUCERS' RESEARCH ASSOCIATION

REPORT FOR 1956

THE research interest in high polymers having industrial uses is very great in this post-war world and the subject has achieved, or almost achieved, academic respectability. Excluding the fibre-forming polymers, which are very adequately catered for in Britain with three research associations and at least two university departments, non-commercial research (namely, that carried out by bodies independent of the commercial interests of a given company) is unevenly distributed over the field of interest. Britain has nothing approaching the T.N.O. Instituut connected with the University of Delft in which studies are being made over the whole field of high polymers, their technical properties and applications. Thus, in Britain, no research association serves the thermosetting plastics industry, and thermoplastics, though largely used by rubber manufacturing companies, are only dealt with unofficially and inadequately.

In contrast with this, the earliest known of the high polymers, natural rubber, has an organization devoted exclusively to its study, besides being one of the main subjects of a research association sponsored by the Department of Scientific and Industrial Research. The British Rubber Producers' Research Association is not so sponsored, but has been, and is, financed solely by a cess raised on rubber exported from British-controlled territories producing rubber. This is now changing: Ceylon has become an independent member of the Commonwealth, and the current annual report of the British Rubber Producers' Research Association* will be the last dealing with work financed before the independence of Malaya was proclaimed. Of an annual income of £214,063 from all sources, approximately £205,000 came from the east, including £183,000 from Malaya. This represents a considerably greater investment in research than the income that the Research Association of British Rubber Manufacturers derives from the industry in Britain (about £50,000 of a total income of £91,000).

The research work of the British Rubber Producers' Research Association is summarized by the director of research, Dr. L. Bateman, in a report consisting of twenty-six pages (including a number of figures and photographs) of technical summary, easily assimilated by the non-specialist reader and emphasizing ends rather than means. Considerable effort is being made to use natural rubber not only as a material in its own right, but also as the raw material from which other high polymers having different properties can be made. Graft polymerization has been studied, a variety of radical additions to the main chain molecules of the rubber being initiated either by high-energy radiation or by the utilization of one of the Association's own discoveries. When rubber is milled in the ordinary course of factory processing, the molecule of high molecular weight is mechanically sheared, two ends being created from the centre of the broken hydrocarbon chain. These two ends are free radicals which normally attack some other molecule or are 'quenched' by atmospheric oxygen. They can equally well, in the absence of oxygen, be used for initiating the polymerization of other active monomeric materials if these are present, and thus comes about an ingenious method of grafting one molecular species on to another. The difficult composite properties of tearing and abrasion are also being actively studied in the physics department, and with the aid of electron microscope studies of replicas of the torn surfaces, the structure at the growing tip of a tear has been examined, not merely for a pure gum rubber, but for vulcanizates loaded with filler particles such as the carbon black used in re-inforcing tyre-tread rubbers.

All this and other work has been published for the free use of the world in a further twenty-four papers in the journals of various learned societies, bringing the total of communications to 241. No other series of papers can have done more than this series in bringing high-polymer studies to the academic rank they now occupy; whether it can assure natural rubber a permanent place in the scheme of things is another matter, but that it has given the natural product a better chance of survival in a man-made world cannot be doubted.

W. C. WAKE

COMMONWEALTH OF AUSTRALIA SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION

REPORT FOR 1955–56

THE eighth annual report of the Commonwealth of Australia Scientific and Industrial Research Organization* covers the year ended June 30, 1956, in which expenditure was £6,266,234, of which £4,716,313 was on normal research activities, £100,431 on grants to the Commonwealth Agricultural Bureaux and like bodies, £10,738 on capital works and the remainder on investigations financed from contributions, which included £873,451 from the Wool Research Trust Account and £317,885 from the Wool Industry Fund. Besides details of personnel of the Council, committees and staff, the report contains a list of papers and patents published during the year. Reference is made to the increasing cost of equipment and the need for financial provision to keep equipment up to date if first-class research workers are to be retained. A permanent Patents Committee has now been established to examine proposals for patents, to review current patents periodically and to decide on the best method of exploiting the Organization's patents for the benefit of the Commonwealth. A contract has been let for a design study for the giant radio telescope, towards which the Radio Astronomy Trust has now more than £520,000 in sight.

Reconnaissance examinations were made of soils in the far north-west of South Australia for comparison with the soils and landscape previously studied at Yudnapinna in the north-west pastoral country: it is hoped that these investigations will assist the solution of some pedological problems there and lead to a better understanding of this arid part of Australia. In field work in the south-east region more emphasis has been placed on an understanding of the principles governing the properties and distribution of soils. Seasonal changes in soil moisture have been followed successfully for two years with a method using neutron scattering as a function of the soil-moisture content, and much attention has been given to a study of the density of organic matter occurring in soils. Bioassays with *Aspergillus niger* and *Curvularia geniculata* indicated that *Aspergillus niger* in general procured more phosphate from insoluble sources than the general microflora, which in turn was better than *Curvularia geniculata*. Attempts have been made to classify foundation problems regionally in areas with soil formations of comparable engineering properties, and also to define certain basic procedures for determining appropriate foundations for domestic buildings.

---

* Eighth Annual Report of the Commonwealth Scientific and Industrial Research Organization for the year 1955–1956. Pp. 180. (Canberra: Government Printer, 1956.) 10s. 6d.

The main research projects of a team in biochemistry and biophysics, recently established to serve as a centre of plant biochemical research, will be concerned with plant metabolism, including a study of the pink pigment in root nodules which are actively fixing nitrogen, studies of plant proteins and their synthesis by the plant, of the mechanism of chlorophyll formation and of the mobilization of sulphur by soil bacteria. Selected introductions of *Phalaris tuberosa* of known origin in the Mediterranean region are being critically examined under different environmental conditions, and the factors determining the onset and breeding of dormancy in selected clones of *Phalaris tuberosa* have been investigated, while in a comparative sward trial, *Bromus inermis* (*C.P.I.* 7073) was outstandingly successful as an associate grass with *Phalaris* and in mixtures with lucerne. Work continued on the preparation of an index to Australian plant genera.

Further investigation of the mechanism of 'active resistance' of plants to fungal disease has led to the separation of an antibiotic principle in plant exudate from infected tissues; this principle results from the interaction between living host tissue and parasite. Big bud of tomato and yellow dwarf of tobacco are being studied with respect to the concentrations of hormone and inhibitor in virus-infected and healthy plants. A survey of a wide range of varieties of apples has shown that low concentrations of oxygen in the absence of carbon dioxide permit the use of low storage temperatures without increasing susceptibility to breakdown. Experiments at Hobart have confirmed that diphenylamine gives greater control of apple scald than any existing treatment, and can be combined with the first wrap. The breeding programme for resistance to blue-mould in commercial flue-cured tobacco was expanded, and promising results have been obtained by pelleting clover seed with lime, thus protecting the *Rhizobium* inoculum from soil acidity and permitting nodulation of clover plants in soils otherwise too acid for survival of the *Rhizobium*. At Canberra evidence is being sought of the effect on animal production of insufficient feed supplies during winter and of poor quality supplies during summer, using various pasture and animal practices, while at Armidale native pastures on non-arable land have been greatly improved by incorporating clover. Two separate studies on the ecology of the riverine plain were completed at Deniliquin.

Among irrigation investigations may be mentioned the studies of the effect of a brief shortage of water on nitrogen, protein nitrogen and phosphorus in the young tomato plant, a preliminary survey of factors associated with accumulation and occurrence of salt in the Murrumbidgee irrigation area, and a study of the permeability of horticultural soils, which indicated the dependence of permeability of subsoils on soil texture and relative density.

The Division of Animal Health and Production followed its normal programme of investigations, and a Cattle Tick Research Committee was established to review progress in this field. In further work on minor elements in the nutrition of sheep, a new and simple method of providing a cobalt supplement has been devised, while investigations of the effect of molybdenum and sulphate on copper metabolism were extended. Further work was done on the treatment of footrot and of internal parasites, as well as on the systemic administration of insecticides against blowfly strike of sheep. Laboratory tests showed that a strain of DDT-resistant ticks was susceptible to BHC, toxaphene and dieldrin, and other research on the cattle tick was concerned with acaricide resistance, and the formulation of dipping fluids.

The Division of Entomology placed increasing emphasis on the study of insect populations and factors which govern the abundance of insects, and these studies are linked with ecological investigations, particularly on pasture pests, such as grasshoppers, cockchafers, caterpillars, and also the earth mite and the lucerne flea, good control of both of which has been obtained with a mixture of malathion and DDT. The digestibility of wool modified in various ways is being investigated to throw light on the mechanism of digestion by *Tineola* proteolytic enzyme. The air-tight storage of grain has been further investigated. The Wildlife Survey Section is surveying the distribution and abundance of marsupials in New South Wales and continued its detailed observations on the epidemiology of myxomatosis and its study of the population of the quokka, *Setonix brachyurus*, on Rottnest Island, Western Australia. Besides further field work in the Georgina Poison Area in northern Australia, the Land Research and Regional Survey Section was responsible for agricultural research in north Australia, and its investigations on natural vegetation at Kimberley Research Station continued, while at Alice Springs broad ecological surveys and plant identification continued.

The Division of Fisheries and Oceanography completed its study of changes in condition in barracouta, and has obtained evidence that sea mullet, ludrick, leatherjacket, flattail mullet, tarwhine, tailor and squire may migrate from Lake Macquari on attaining maturity. Electrical fishing equipment was used for comparing the fish population above and below the natural barriers formed by waterfalls in rivers which had received no hatchery fish for several years. Investigations of the ecology of the sulphur cycle continued, and the relative sensitivity of various marine fouling larvæ to copper and mercury is being studied.

The Division of Food Preservation and Transport is studying the effects on citrus fruit from the districts of Queensland of recommended post-harvest treatments for killing fruit-fly larvæ and eggs in the fruit. It is also investigating the volatile substances produced by fresh apples in their bearing on storage behaviour and superficial scald. The water requirements of several strains of *Clostridium botulinum* have been determined, and studies of the factors fatal to micro-organisms in dried storage continued, together with work on the time of application of the sodium *o*-phenylphenoxide dip for control of mould in oranges. The limits for desirable harvest-maturity of peas for canning have been determined, and work has commenced on the evaluation of different varieties: a study of maturity relations at Hawkesbury Agricultural College suggested that peas for dehydration should be harvested at least one day before peas for canning. New chromatographic techniques are being applied to the isolation and identification of phospholipids as a step towards elucidating their role in deterioration of the flavour of milk. Thermoduric starters have been found to contribute appreciably to acid production in the manufacture of Cheddar cheese by the new short-cheese process, and defects due to high *p*H in cheese made by this method have been corrected.

The Division of Forest Products studied liquefaction in the differentiating xylem of *Pinus radiata* and various species of *Eucalyptus* at different times in the growth-cycle, the factors influencing the rate of reaction of the hydroxyl groups of fibrous cellulose, the sorption characteristics of components isolated from *Eucalyptus regnans* and methods for the diffusion treatment of green timber. Building research included studies of the initial stages of the hydration of calcium sulphate, of the expansion of clay bricks on exposure to moisture, of the rheological properties of roofing bitumens and of the reverberation times of concert halls in Victoria. The investigation of the acids present in suint continued and work was commenced on the preparation of esters from wool-wax acids with a view of possible use as plasticizers. The radioactive-tracer technique has been used for determining the amount of residual crimp in two types of wool differing only in the number of crimps per inch. The rate and extent of combination of typical anionic, cationic and non-ionic detergents with wool fibre is being studied with reference to the uptake of dyes by wool. A continuous process for shrink-proofing woven fabrics with casein has been evolved, while industrial trials indicate that application of 0·05 per cent dieldrin in the dyeing, bleaching or milling operations affords a protection against moths which is fast to dry-cleaning and resistant to atmospheric exposure. An extensive programme was also undertaken on the mechanical properties of wool.

In the Division of Industrial Chemistry work continued on the acid leaching of copper from calcinates produced in the fluo solids roasting of chalcopyrites concentrates, and also on the Division's process for the preferential leaching of uranium by sulphuric acid autogenously produced from pyrites present in or added to the ore. The separation of zirconium and hafnium tetrachlorides by preferential reduction of zirconium to the trivalent state has been developed to a semi-continuous process and a study of the behaviour of zirconium carbide electrodes in fused salt baths was commenced. Increased attention was paid to the purification of thorium, including preliminary studies of the iodination of crude thorium, and chemical extraction tests promise economical extraction of germanium from the flue dust from coal-fired boilers of power-generating stations. A new approach was developed in the study of the strength of concretes, and the load-bearing capacity of plastic specimens of clays was related to the aqueous content over a narrow range.

A new theory of simple liquids was developed to give a satisfactory description of the critical regions of density and temperature, studies continued on the reinforcement of rubber by carbon black and a new process was developed for direct extraction of uranium from an ore pulp. Further calculations have been made on the energy-band structure of ionic solids and its relation to their optical properties, new types of electronic voltage stabilizers have been developed, while much effort was given to increasing the sensitivity of the small mass spectrometer and the stability of its power supplies. By reformulating conventional physical optics in terms of the Fourier transform and convolution concepts a new approach has been obtained which can profitably be applied to a wide range of problems in light and electron optics. Examination of the *Alstonia constricta* alkaloids and the study of pyrrolizidine alkaloids continued, as well as that of the seed fat of *Mallotus philippinensis* of Australian origin for its potential use as a drying oil. Besides basic studies of the characteristics of fluidized beds, data were accumulated for the design of large fluidized-bed reactors and a pilot-plant investigation was made of the fluidized-bed roasting of copper concentrates.

Fuel research is mainly confined to coal, including studies of the changes in the X-ray diffraction of cokes and chars with rising carbonization temperature, of the chemical mechanism of the formation of coke from coal, of the relation between flow of air and drop in pressure through fuel beds and the design of a new type of automatic recording balance, of a differential thermogravimetric balance to measure the rate of thermal decomposition of coal in coking, as well as studies on the properties and constitution of coal tar. In physical metallurgy attention was directed to the strength at high temperatures of titanium–niobium alloys which are mixtures of α- and β-solutions, while the Division of Tribophysics extended its studies of the adsorption of long-chain polar compounds on solid surfaces to include the adsorption of detergents, and has used the differential method of determining small changes in density to measure those which occur on annealing deformed nickel.

In the Division of Physics, demonstration of the precision, speed and reliability of the new absolute method of measuring humidity was a feature of the work during the year. Research continued on the basic structure of metals and alloys as deduced from studies of their thermal and electrical properties at very low temperatures, and crystal imperfections produced by cold work were measured quantitatively. Besides a survey of the radio-noise levels throughout Australia and work on the growth of monocrystals of germanium and silicon, on the development of alloyed junction transistors capable of switching large currents and on the distribution of charge carriers in a semi-conductor under non-equilibrium conditions, the Division of Radio Physics has further developed equipment to study the spectra of solar bursts at metre wave-lengths and the very high resolution of the distribution of radio brightness over the solar disk at decimetre wave-lengths. The Radio Research Board has found that the radio effects can be predicted once an ionospheric storm has begun and the practical application of this information is being investigated.

In atmospheric physics the study of interactions between monsoonal and general circulation in the Australian region is being extended to the trade-wind region and the distribution of rainfall over the continent. Work on the development of an accurate automatic method of measuring evaporation from natural surfaces, including growing crops, has reached an advanced stage. Measurements of the size and concentration of droplets in maritime and continental cumuli have shown that the droplet-concentration is systematically higher in continental cumuli, and further tests on artificial rain formation indicate that if seeding with silver iodide is to succeed the particles must be generated under conditions which ensure that they reach the supercooled regions of the atmosphere as soon as possible after release.

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

REPORT FOR 1956

In these eventful times, when so much is heard of atomic research and nuclear power, it is all too easy to forget that the production of good-quality food in amounts that will meet the needs of the world's ever-increasing population is one of the most important problems on which intensive scientific research is still urgently required. With this in mind, it is cheering to turn to the annual report of the National Institute for Research in Dairying, and to realize that so much work is being done on the production, properties and utilization of milk and milk products, and that so much detailed study is being made in the various sciences on which the dairy industry in all its many branches closely depends.

The Institute was founded forty-five years ago, and even a cursory glance at the report for 1956* is sufficient to show what marked progress it has made in recent years, and how clearly the action of those who founded it at Reading in 1912 has been justified. The total number on the staff in 1956 exceeded three hundred, more than one hundred of whom were graduates in one or other of the many branches of science. The Institute now has eight principal departments, covering dairy husbandry, feeding and metabolism, physiology, nutrition, bacteriology, chemistry, physics and engineering. In addition, there are sections that deal specifically with isotopes and statistics, and a unit the duty of which is to maintain liaison with the dairy industry.

In the foreword of the report more than four pages are devoted to a very brief but highly informative outline of some recent investigations. The reader who wants to know at a glance what the Institute does, how its work adds to existing knowledge and how its findings apply to the dairy industry will find this short section particularly valuable. For the more leisurely reader this part of the report is followed by more than a hundred pages in which an account is given of the work of each of the main departments and units. Finally, for those who may be working in allied fields of research or who may require full details, a list of the Institute's recent publications is given with titles and references. More than 150 papers are cited in the list, most of which were published in 1956.

Many of the problems under investigation are likely to give results of immediate importance in some branch of the dairy industry. Such, for example, are the studies that are being made of the milking machine and the milking technique itself, the sterilization of milk bottles, the ripening of cheese in modern types of wrapping and the ultra-high-temperature sterilization of milk. But in addition to work like that on subjects of immediate practical importance, the Institute has for many years enjoyed a well-merited reputation for the excellence of its fundamental work, particularly in the physiology of lactation and in the realm of nutrition. Among the many topics that fall into this category, mention is made in the report of research on the biosynthesis of carbohydrate by mammary gland tissue for which glucose labelled with carbon-14 was used. This study has shown that the galactose required for lactose formation is made from glucose in the mammary gland itself, and that pyruvate is not a precursor of lactose. Another piece of fundamental work has shown that the two β-lactoglobulins of cow's milk differ in their crystal forms but have almost equal molecular weights. Yet another deals with the relations between the hormones oxytocin and prolactin in their influence on the mammary gland and on lactation. Statistical methods are being increasingly used in many of the Institute's investigations, and in the past year they have been applied to a variety of problems, such as manurial trials with kale and cabbage, pasture evaluation and the assay of prolactin.

It is good to know that in Britain, which at present produces only some 40 per cent of its own food, so much research work of this high standard is in progress in problems related to the important industry of dairying.

WESTERN EUROPEAN CO-OPERATION

The broadsheet "Designs for Europe" (No. 414, September 16, 1957), issued by Political and Economic Planning, follows two earlier broadsheets: No. 405 (December 17, 1956), which gave a summarized translation of Part 1 of the Spaak Report, dealing with the Common Market, in which are outlined the proposals for the merging of markets, the policy to be pursued for the common market, and the development and use of Europe's resources; and No. 412 (July 15, 1957), "Free Trade and Social Security". This broadsheet quotes the Government's view expressed in the White Paper, "A European Free Trade Area", that it was not considered essential, in order to achieve the degree of effective competition necessary for the functioning of the Free Trade Area, that agreement to remove the disparities between the social regulations in different countries should precede or be a necessary condition of the creation of such an Area; it also summarized social security policies in Europe and described national schemes in France, Germany, Italy and Sweden before considering the possibility of international action. The broadsheet points out that there was insufficient information for a final opinion on the effects of great economic integration on social security policies and vice versa and that further research was needed.

---

* National Institute for Research in Dairying: University of Reading. Report, 1956. Pp. 158. (Shinfield: National Institute for Research in Dairying, 1957.)

"Designs for Europe" begins by reviewing the principal European organizations set up since the War—the Economic Commission for Europe, the Organization for European Economic Co-operation, Western European Union, the North Atlantic Treaty Organization, the Council of Europe, the European Coal and Steel Community, European Economic Community and the European Atomic Energy Commission. It then goes on to Britain's relations with Europe, and emphasizes the strong practical reasons for some rationalization of these organizations.

The concept of a single European Assembly to co-ordinate the activities, interests and objectives of all these varied and overlapping organizations is generally regarded as unworkable, but Political and Economic Planning suggests that it might be practicable on more limited fronts, particularly separate attempts to rationalize organizations concerned mainly with economic and military affairs, thus avoiding the difficulty of linking economic and military co-operation. It is suggested that the Consultative Assembly of the Council of Europe should become the Assembly of the Organization for European Economic Co-operation while continuing its present varied activities, and that this body might become the principal European economic assembly in which all Western European countries would meet. If a free trade area was established, the Organization for European Economic Co-operation would be the most appropriate body to control its work.

The most successful role of the Economic Commission for Europe is considered to be in furthering technical co-operation, and it is emphasized that, wherever possible, duplication of technical co-operation in other economic organizations should be avoided. No valid justification is seen for the continued separate existence of the North Atlantic Treaty Organization and Western European Union, and it is suggested that the Assembly of the latter body might be widened into a North Atlantic Treaty Organization assembly. European co-operation, PEP concludes, is in danger of becoming ineffective, through lack of co-ordination. The whole pattern of European co-operation would be simplified by creating out of existing organizations a general economic and defence assembly for the West.

TORNADOES IN GREAT BRITAIN

THE tornado is a relatively thin, roughly vertical column of air rotating at very high speed about a central axis in which the pressure is markedly less than in the surrounding air. The reduction of pressure leads to condensation of water vapour in the inflowing air to produce a cloud along the axis of the tornado, shaped roughly like a giant elephant's trunk. In its more intense forms the tornado is the most violent and destructive of small-scale meteorological phenomena. The damage produced is caused by the direct battering of the high wind, the twisting effect of the very great shear of wind outwards from the axis, the lifting effect of the intense vertical currents along the axis and the explosive effect of the sudden reduction of pressure as the axis crosses buildings. The tornado moves with the general wind-current, causing damage where it touches the ground along a track ranging from a few feet to a hundred yards in width. Tornadoes are always associated with heavy thunderstorms, and the rotation is clearly a dynamical phenomenon associated with convergence of air flow towards an axis, but a fully satisfactory theory explaining all their properties has not yet been produced.

The central plains of the United States in spring suffer more than anywhere else from tornadoes, probably because contrasts between adjacent air masses—in that region and season between air from the Gulf of Mexico and air from the Arctic north of America—are sharper than elsewhere and so produce more intense convection.

In the British Isles destructive tornadoes are comparatively infrequent. An examination of published reports showed a total of fifty-four in the eighty-three years from 1868 to 1950, and most of these caused only minor damage. However, on May 21, 1950, there formed over the north-west part of the Chilterns a tornado which was more violent than most of those which cause damage in the United States.

This tornado is comprehensively described by Mr. H. H. Lamb in Meteorological Office Geophysical Memoir, No. 99*. Mr. Lamb and Mr. J. Simmonds, then both of the Central Forecasting Office, Dunstable, which was close to the track, made a thorough investigation of the tornado in the days immediately following it. The tornado was first noticed near Wendover, Buckinghamshire, at the western end of the Misbourne Valley, whence it moved north-eastward to the Fen country, causing serious damage in places where it touched the ground. The place worst affected was Linslade, where damage to the value of £25,000 occurred. Sheets of corrugated iron were carried for half a mile through the air. The great reduction of pressure in the centre is shown by the fact that it lifted water in a duckpond to a height of 10 ft., which affords a rough estimate of the reduction of pressure as about one-third, since the height of the water barometer near sea-level is about 30 ft. The only known photograph, reproduced in the Memoir, of a tornado in Britain was taken by an airman at the R.A.F. Station at Halton as this one passed over.

The Memoir gives a full account of the meteorological situation and, from the damage to trees and from winds recorded by anemometers a mile or so from the track, of the structure of the tornado. Mr. Lamb points out that the first tornado and its regenerations occurred at the openings of valleys at right angles to the general wind, where there would be an initial curving of flow to stimulate the spin. The sense of rotation in this instance appears to have been cyclonic (counterclockwise), but this is not always so and a tornado of anticyclonic rotation has since occurred in France (*La Météorologie*, Paris, 317; 1955).

A comparison of the observations with the theories of causes of tornadoes is given. The Memoir concludes with a note on the climatology of tornadoes in Britain which clearly exhibits the correspondence of areas of maximum frequency of both thunderstorms and tornadoes.

It is interesting to note that on the thundery, squally afternoon of December 8, 1954, there was a sharp tornado to the west of London which caused severe damage along a line from Chiswick through Acton to Golders Green. A description with a radar photograph is given in the *Meteorological Magazine*, 84, 320; 1955.

FOREST RESEARCH IN BRITAIN

It is now about ten years since the Forestry Commission Research Station at Alice Holt was opened, and the Commission's Research Branch, which might previously have been described with only slight exaggeration as 'a one-man show', was enlarged so as to enable it to deal more adequately with the diversity of problems which are encountered in the practice of forestry. The annual Report on Forest Research in Britain*, which prior to 1950 had been a modest, privately circulated document, has now become a publication which is essential to anyone who wishes to remain informed on modern developments of forestry technique. It reports not only the progress of work by the Commission's own research branch, but also of work carried out with the support of the Commission in university departments, and although the detailed results of most of this latter research will usually be published elsewhere, the report of the Research Branch provides a compact and often early summary.

The present phase of the Commission's research is essentially one of consolidation and continuation of work which was started after the expansion of 1947; many new developments cannot be expected. For the first time, however, the soil chemist now attached to Alice Holt reports on his work, which has been largely of a preliminary and routine nature, including the analysis of plant tissues in addition to that of soils. Economics was the principal branch of forest research which was unrepresented during 1955–56; this deficiency has now been made good by the appointment of a district officer for economics research.

The practice of forestry draws upon a wider range of techniques than do most comparable arts, and accordingly the investigations carried out by or for the Commission range over subjects as diverse as the performance of planting machines and the biology of oribatoid mites. Much of the work is of a simple kind and is designed to decide practical details in technique. It is sufficient to note here with satisfaction that these details are being made the subject of thorough investigation and that many new procedures, some of them unconventional, are being explored; the impression is given that the Commission's research staff is fully alive to the need for constantly reviewing forestry technique as new methods become practicable and as economic conditions change.

It is appropriate here to direct attention to some of the research which has a wider scientific interest. Dr. Rishbeth's work on the fungus *Fomes annosus*, which has already yielded such important results, has been resumed, and the Commission's research branch is energetically studying its practical implications. The fungi *Meria laricis* and *Keithia thujina* are becoming the subjects of intensive study at the Universities of Southampton and Nottingham respectively. Dr. Manners's work at last seems to be deciding the relative importance of frost and of the fungus *Trichoscyphella* in causing larch canker.

Entomological work has been dominated by the pine looper moth, *Bupalus piniarius*, but the larch sawflies and the pine weevil, *Hylobius abietis*, have also received attention, and the discovery at many stations in Scotland is reported of the bark beetle *Ips cembrae*, a potentially serious pest of larch. The distribution of red and grey squirrels is noted.

The application to the soil of formalin and alternative sterilizing agents is still being studied; it is now reported that the resulting stimulation of tree seedlings cannot be ascribed to the destruction of fungi parasitic on the roots. Other investigations concern the use of fertilizers, a copper deficiency on heathland soils, and the action of mycorrhizæ. Dr. Murphy's report on the biology of oribatoid mites which live in forest litter is also noteworthy. E. W. Jones

THE GOLGI CONTROVERSY

By Prof. VISHWA NATH

Department of Zoology, Panjab University, Hoshiarpur, India

Under the above title, J. R. Baker[1] has very ably summed up the evidence in favour of his now well-known view that we should concentrate on an objective study of the cytoplasmic inclusions and discard once for all the use of the terms 'Golgi apparatus', 'Golgi bodies', 'Golgi substance', etc. He has marshalled his evidence under three headings: (*a*) evidence from morphology; (*b*) evidence from histochemistry; and (*c*) evidence from ontogeny.

The purpose of this communication is to scrutinize the evidence furnished by the school of cytology at Oxford in the light of our own work done in the Department of Zoology, Panjab University, Hoshiarpur, and see if we can arrive at some definite conclusions.

(*a*) *Evidence from morphology*. Baker[1] has given three examples of the many different kinds of cells that he and his colleagues have examined.

(i) Neurones of the thoracic ganglia of *Locusta*. Shafiq[2], working on the neurones of *Locusta*, describes only two cytoplasmic inclusions, namely, (*a*) homogeneous globules stainable in life by neutral red (lipochondria), and (*b*) filamentous and granular mitochondria, stainable by janus green. Shafiq[2] used the osmium and silver 'Golgi techniques' on the lipochondria and observed that the lipochondria now reveal a black cortex and a pale medulla; and he interpreted these appearances as artefacts.

In our laboratory, Malhotra[3] has worked on the neurones of *Schistocerca* and *Laccotrephes*, *Anadenus* and *Euaustenia*, and *Pheretima*, respectively. Malhotra generally supports Shafiq, but has seen and photomicrographed the duplex structure of the lipochondria under phase-contrast in the living cell and also in sudan black preparations. Malhotra, therefore, comes to the conclusion that the duplex appearances in Golgi techniques are not artefacts. It may be noted that neither Shafiq nor Malhotra describes a 'Golgi network'.

(ii) Sympathetic nerve cell of the mouse and rabbit. Thomas[4], Baker[5] and Casselman and Baker[6] made observations on this material and detected only two cytoplasmic inclusions large enough to be visible with the light microscope, namely, spherical or spheroid globules stainable with neutral red, and mitochondria. Thomas described the globules as "binary spheroids", Baker as "Golgi elements" and Casselman and Baker as "lipochondria". Thomas[4] also showed how the typical Golgi network is produced in the Mann–Kopsch technique.

In this laboratory Malhotra[7] has worked on the ageing spinal ganglion cells of *Rana tigrina* and the spinal ganglion cells of the rabbit and squirrel. He has confirmed the findings of the Oxford school as given above, and he has also shown very clearly in the neurones of the tadpole that the "Golgi reticulum" described earlier by Gatenby *et al.*[8] and Moussa and Banhawy[9] does not exist in the living cell examined under phase-contrast.

(iii) Intestinal epithelial cell of the mouse. Baker[10] and Casselman[11] worked on this cell. With Golgi techniques there appears a complicated reticular object in the cell, situated near the nucleus, on the side towards the free border of the cell. When this part of the cell is examined in life, or in frozen sections, a different picture is given. One sees globules of various sizes, but there is a special substance, differing chemically from the ground cytoplasm, between the globules; but since it is transparent and evidently of the same refractive index as the cytoplasm, it has not been seen in the living cell. To find how the Golgi reticulum is formed, osmication was tried. It was noticed that osmium was first deposited in or on the globules, and a life-like picture was thus produced. But when osmication is prolonged to give the usual Golgi picture, osmium is also deposited in the material that lies between the globules. It is this stringy deposit that forms the Golgi reticulum of this particular cell. Casselman[11] identified this material lying between the globules as neutral mucopolysaccharide.

In our laboratory, Rishi[12], working on the liver cells of *Anadenus*, failed to detect any 'Golgi networks' in this material; and in the living cell under phase-contrast as well as in the material prepared by Golgi techniques he could see lipid spheroids and filamentous mitochondria only. Likewise, Chand (unpublished work) has not observed Golgi networks in the exocrine cell of the rat pancreas.

(*b*) *Evidence from histochemistry*. The most valuable contribution of the Oxford school is with regard to the histochemistry of the so-called Golgi bodies. Here again the same three cells were selected. The neurone of the locust was studied by Shafiq and Casselman[13]. Their purpose was to determine the chemical composition of the globules in the cytoplasm on which osmium is deposited by the Golgi techniques. It was concluded that the globules consisted of phospholipid and cerebroside.

In this laboratory, Guraya[14] has worked out the chemical composition of the lipid contents of the pigeon oocyte. The mitochondria ($L1$), according to him, consist of fatty acids, phospholipids, triglycerides and proteins. The so-called Golgi bodies of other authors consist of phospholipids and triglycerides ($L2$). These last seem to give rise to the 'fatty yolk' of Nath[15], which consists of triglycerides, cholesterol, and cholesteryl esters ($L3$). In addition, Guraya describes some lipid bodies which appear at the periphery of the oocyte and which consist of phospholipids and triglycerides (PL). These last do not seem to have any connexion with $L2$ and $L3$. Again, Guraya has described at a comparatively early stage of oocyte growth a juxta-nuclear mass of bodies consisting of lipoproteins. Finally, he has described compound yolk bodies consisting of triglycerides, phospholipids, protein and possibly carbohydrates.

Work on the histochemical studies of the cytoplasmic inclusions in the eggs of reptiles, fishes, frog, cockroach, *Culex*, *Chrotogonus* and spiders being carried out in our laboratory points towards the conclusion that there are more than one type of lipid bodies in an egg, and in some cases the 'albuminous yolk bodies' of previous authors also contain large quantities of lipids of different types. It has become clear that there are considerable differences in the detailed chemistry of the lipid bodies of different eggs.

Casselman and Baker[6], working on the sympathetic neurones of the rabbit, came to the conclusion that the lipochondria consist of cerebroside and phospholipid.

Casselman[11], working on the intestinal epithelial cell of the mouse, showed that the lipochondria consisted of neutral lipid having a higher degree of saturation than the triglycerides of storage fat. The substance in which the lipochondria were embedded was found to be neutral mucopolysaccharide.

(*c*) *Evidence from ontogeny*. Under this heading Baker[1] argues that there is no genetic continuity of the so-called Golgi bodies in successive cell generations. He quotes Roque[16], who did not observe any traces of his 'paranuclear bodies' (Golgi bodies of other authors) in the spermatogonia or early primary spermatocytes of *Helix aspersa*.

In our laboratory, we have carried out extensive investigations on the spermatogenesis of three pulmonate gastropods (Nath and Chopra[17], Nath and Gupta[18]) and have shown that the Golgi dictyosomes in our material are absent from spermatogonia, early meiosis I and early meiosis II.

Reference may be made to Nath[19] for examples of numerous germ cells in different animals which lack the Golgi apparatus.

Conclusion. The Golgi network was considered as an artefact first by Schlottke[20], then by Hirsch[21], and eventually by Nath[22] and Baker[5]; the discrete Golgi bodies described by numerous authors have no homology whatsoever with the classical 'apparato reticolare interno' described by Golgi. Again, it has been shown clearly that the so-called Golgi bodies do not have a fixed chemical composition even in the same cell. Lastly, the so-called Golgi bodies have no genetic continuity.

It seems, therefore, best to accept the view of Dr. Baker—a view which has been very ably advocated—that we should discard the terms 'Golgi apparatus', 'Golgi bodies', etc., and concentrate on an objective study of the cytoplasmic inclusions in the cell.

VISUAL PIGMENTS AND DEPTHS OF HABITAT OF MARINE FISHES

By Prof. GEORGE WALD, PAUL K. BROWN and PATRICIA SMITH BROWN
Biological Laboratories of Harvard University, Cambridge, Mass.

IT has long been known that the rods of coastal marine fishes contain the red visual pigment rhodopsin, with its wave-length of maximum absorption ($\lambda_{max.}$) about 500 mμ[1]. Recently, Denton and Warren[2] have reported that several species of fish taken at depths of about 500 metres (about 275 fathoms) possess a visual pigment with $\lambda_{max.}$ about 480 mμ. These workers did not extract the pigment, but measured its difference spectrum in fresh retinas. They described its colour as golden, and suggested that it be called chrysopsin, or visual gold.

Munz[3] has since extracted visual pigments from fishes taken at night at 280–380 fathoms, the $\lambda_{max.}$ of which ranged from 478 to 490 mμ. Munz found one species in which a pigment with $\lambda_{max.}$ 478 mμ occurs together with ordinary rhodopsin of $\lambda_{max.}$ 500 mμ. All these pigments yielded retinene$_1$ on bleaching.

The observation that deep-sea fishes possess different visual pigments from shoal-water fishes prompts the question, at what depth does this difference occur? One should scarcely expect the pigment to change abruptly at some specific depth; and indeed it does not. Fig. 1 shows the absorption spectra of visual pigments extracted from a number of marine fishes which frequent depths of less than 100 fathoms, and from the lancet-fish, ordinarily found below 200 fathoms. The lancet-fish visual pigment has $\lambda_{max.}$ 480 mμ, like the deep-sea forms described by Denton and Warren; the pigments from fishes from shallower waters range in $\lambda_{max.}$ from 494 to 503 mμ. These and Munz's observations make it clear that the visual pigments of marine fishes exhibit a continuous range of $\lambda_{max.}$, between the present limits of 478 and 503 mμ.

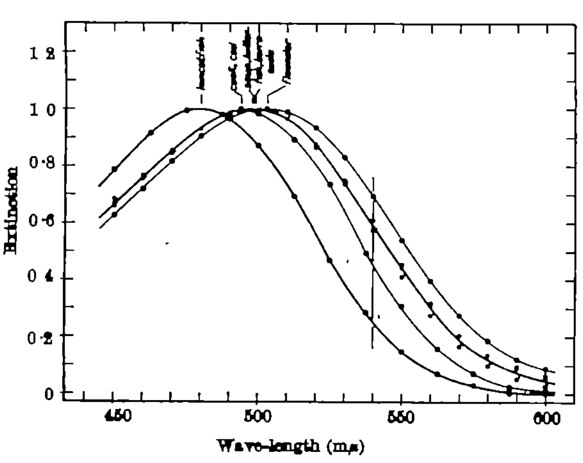

Fig. 1. Absorption spectra of rhodopsins from marine fishes, in 2 per cent aqueous digitonin solution. Scup, butterfish, barracuda and flounder are typically surface forms; cusk and cod come from middle depths; and the lancet-fish is a deep-sea form. The maximum absorption ($\lambda_{max.}$) shifts toward shorter wave-lengths in rough correlation with the depth. A more accurate index of the shift of spectrum is the ratio of the extinction at 540 mμ to that at the maximum ($E_{540}/E_{max.}$)

Table 1

Species	Summer range of depth (fathoms)	$\lambda_{max.}$ (mμ)	$E_{540}/E_{max.}$
Summer flounder (*Paralichthys dentatus* Linnaeus)	2–10	503	0·695
Scup (*Stenotomus versicolor* Mitchill)	1–20	498	0·586
Butterfish (*Poronotus triacanthus* Peck)	1–30	499	0·610
Barracuda (*Sphyraena borealis* DeKay)	1–10*	498	0·575
Cod (*Gadus callarias* Linnaeus)	5–75	496	0·530
Cusk (*Brosme brosme* Muller)	10–100	494	0·455
Lancet-fish (*Alepisaurus ferox* Lowe)	> 200	480	0·250

* Bigelow, H. B., personal communication.

Our observations, though altogether too few to fix the relationship, suggest that within these limits a rough correlation exists between depth and the wave-length of maximum absorption ($\lambda_{max.}$). Nothing exact can be sought in this regard, since fishes wander greatly in depth, and since it is already clear that a wide spread of $\lambda_{max.}$ exists at all depths. Nevertheless it seems significant that the fishes we have examined that inhabit middle depths also exhibit intermediate values of $\lambda_{max.}$: the cod, which ranges mainly from 5 to 75 fathoms, with $\lambda_{max.}$ 496 mμ; and the cusk, found ordinarily at 10 to 100 fathoms, with $\lambda_{max.}$ 494 mμ (Fig. 1, Table 1).

(*Note added in proof*: Since this paper was written, we have examined the rosefish (*Sebastes marinus* Linnaeus). It frequents the intermediate depth-range of 40–175 fathoms; and the $\lambda_{max.}$ of its visual pigment is 488 mμ.)

Actually, as is apparent in Fig. 1, a better basis than $\lambda_{max.}$ for making such comparisons is the ratio of the extinction at 540 mμ to that at the maximum ($E_{540}/E_{max.}$). In such broad absorption bands it is difficult to specify $\lambda_{max.}$ accurately, whereas E_{max} and E_{540} can be read with precision. The possibility that these extinctions have been raised by contaminants can be obviated by bleaching the pigment with light in the presence of hydroxylamine, and using the changes of extinction as the measure of the visual pigment.

Both $\lambda_{max.}$ and $E_{540}/E_{max.}$ for the fishes we have examined are listed in Table 1, together with characteristic summer depth-ranges[4]. In Fig. 2 both indices are plotted against depth. For the reasons already stated, the data are altogether too meagre to specify the form of this function. They are intended to do no more than indicate the trend of an emerging relationship.

What is the chemical basis of the displacement of spectrum? Rhodopsin is formed by the combination of a hindered *cis* configuration of retinene, called neo-*b* (11-*cis*), with opsin; and bleaches to a mixture of all-*trans* retinene and opsin[5]. The visual pigments of the lancet-fish ($\lambda_{max.}$ 480 mμ) and cusk ($\lambda_{max.}$ 494 mμ) exhibit the same properties. Each of these pigments bleaches in orange (non-isomerizing) light to a mixture of all-*trans* retinene and opsin, which on incubation in the dark with neo-*b* retinene regenerates the original photosensitive pigment (Fig. 3). It may be concluded that all these visual pigments, since identical in prosthetic group, owe their differences in spectrum to the possession of different opsins.

It is a truism in biochemistry that each species of animal and plant possesses specifically different proteins. All hæmoglobins have the same prosthetic group, ferrohæm, united with a type of protein called globin, which differs in every species so far examined. The hæmoglobins differ in oxygen affinity, kinetics of reaction, stability, absorption spectrum, and other properties. Indeed, the hæmoglobins of invertebrates differ characteristically from those of vertebrates[6]. Yet because all these substances are ferrohæm-proteins which share a few general properties, it has proved useful to call them all hæmoglobins.

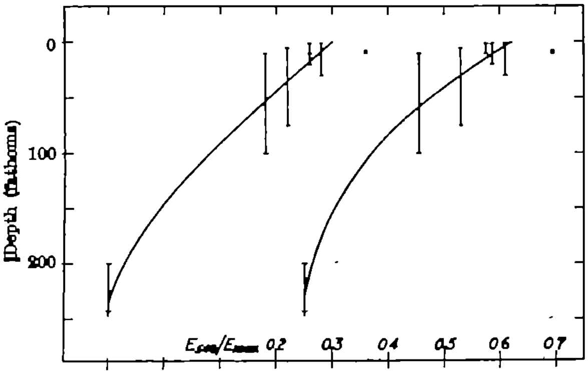

Fig. 2. Variation of absorption spectra of rhodopsins of marine fishes with summer range of depth. Left $\lambda_{max.}$; right E_{540}/E_{max}

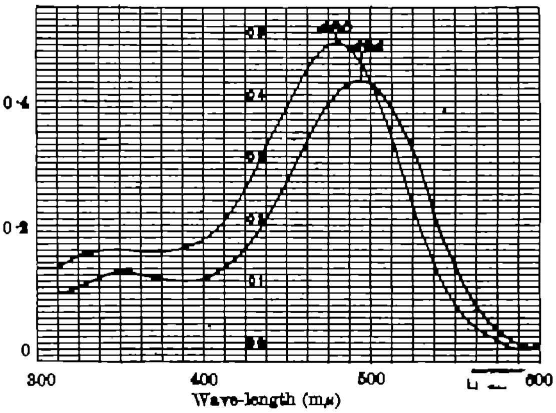

Fig. 3 The rhodopsins of the lancet-fish ($\lambda_{max.}$ 480 mμ) and cusk ($\lambda_{max.}$ 494 mμ) were bleached with orange light to mixtures of all-*trans* retinene and opsin. On incubating these in the dark with neo-*b* (11-*cis*) retinene, the rhodopsins characteristic of these fishes were regenerated. The spectra of the regenerated pigments are shown, as drawn by a recording photoelectric spectrophotometer

The rhodopsins are in a precisely parallel position. We define them as a class of visual pigments composed of neo-*b* retinene united with a type of protein found in vertebrate rods, called rod opsin or scotopsin. The pigments found in certain invertebrate eyes—squid[7], lobster[8]—have the same prosthetic group, and resemble vertebrate rhodopsins so closely as to make it useful to call them also rhodopsins. Each rhodopsin can be characterized specifically by the name of the animal which possesses it—thus cattle rhodopsin, squid rhodopsin. Each is composed of a different opsin, and with this go differences in stability, kinetics of synthesis and bleaching, absorption spectrum, and other properties.

In accordance with this definition, we should like to call the pigments of deep-sea fishes rhodopsins. Since they exhibit, as do rhodopsins generally, considerable variation in λ_{max} and since they appear to lie at one extreme of a continuous transition from surface forms downward, we think it unfortunate to give them a special name, unless to call them deep-sea fish rhodopsins. Indeed, where otherwise is 'rhodopsin' to end and 'chrysopsin' to begin?

It seems probable that the rhodopsins of marine fishes do not greatly transcend the limits already disclosed. As Denton and Warren indicate, vision is not possible with light penetrating from the surface at depths greater than those already sampled[1]. These authors note also that the displacement of spectrum observed in deep-sea fishes appears to be a significant adaptation to the quality of light penetrating into the sea. In coastal waters, green light penetrates most effectively; whereas in such deep waters as the Sargasso Sea and Gulf Stream, blue light reaches by far the greatest depth[10]. Indeed, Clarke, discussing some twenty years ago the increasing blueness of light with depth in the ocean, commented, "These results raise the question of the possibility of a shift in the sensitivity of the eye of a deep-water fish toward the blue end of the spectrum"[9]. This possibility has now been realized in the observations of Denton and Warren, which open a new and unexpected chapter in biochemical ecology.

This investigation was supported in part by funds from the Rockefeller Foundation and the Office of

Naval Research. We are indebted to the Marine Biological Laboratory, Woods Hole, Mass., for scup, butterfish and summer flounder; to the Globe Fish Co. of Boston for cusk and cod; to the Lerner Marine Laboratory of Bimini, British West Indies, for barracuda; and to Mr. James Squire, of the Boston Office of the U.S. Fish and Wildlife Service, for lancet-fish.

THERE is considerable evidence to indicate that in globular protein molecules the polypeptide chains are folded or coiled in some specific arrangement[1]. By means of end-group analysis, it is possible to obtain an estimate of the number of sub-units or individual chains in the molecule[2]. Branched peptide chains are unknown among the globular proteins[3]. Detailed single-crystal studies of a limited number of proteins have shown the presence of parallel rods of high electron density in the crystal structure[4]. The rods, which were of circular or elliptical cross-section, were in close-packed array and probably correspond to coiled polypeptide chains in the molecular structure. Undoubtedly, hydrogen bonds and salt linkages play an important part in maintaining the structure of the native protein molecule and also in holding the sub-units together where these occur.

When proteins are denatured by the action of such reagents as bases, urea, guanidine compounds, etc., the specific, internal structure of the protein undergoes alteration[5]. The closely folded polypeptide chains become unfolded in an irregular arrangement contrasting sharply with the compact native molecule. As a result of the unfolding, some of the reactive groups of the protein which were inaccessible to different reagents now become accessible. Denaturation usually results in radical alterations in the solubility and viscosity of the protein, and frequently in changes in molecular weight. The denatured molecules can usually form fibres[5]. The X-ray diagram of denatured globulins is similar to that of disoriented β-keratin (super-contracted), while on stretching orientation becomes more complete, the resulting diffraction pattern resembling that of fully extended β-keratin[6].

Wormell[7] has put forward a theory that the protein molecules remain globular or corpuscular even after denaturation. He contends that the protein molecule is composed of a number of polypeptide chains converging at the centre of the corpuscle, the chains forming loops and folding back on themselves. In the denatured state, the protein is considered to be like the pappus of a dandelion; but, before denaturation, more like the bud. Thus, according to this view, denaturation is merely the swelling of the corpuscle as a result of unfolding of the radial chains. No explanation is offered by this theory for the considerable reduction in molecular weight which frequently occurs on denaturation—for example, with the globulin arachin[8], which constitutes the major fraction of the proteins of the groundnut (*Arachis hypogaea*).

A considerable amount of work has been reported on arachin, and the purpose of this communication is to collect this information with other unpublished results obtained recently in these laboratories in order to arrive at a clearer picture of the structure of arachin and the changes it undergoes upon denaturation.

Undenatured arachin. Johnson and Shooter[9] by sedimentation velocity and diffusion measurements showed that the molecular weight of arachin is 330,000. Johnson and Goring[10] obtained the same figure by light-scattering techniques.

The first authors, also by sedimentation and diffusion measurements, demonstrated that arachin dissociates into half-molecules of molecular weight about 170,000 on reducing the ionic strength of a solution. The position of equilibrium favoured the dissociated state at high *p*H values, but the rate at which equilibrium was achieved was greater at lower *p*H values. Arachin prepared by ammonium sulphate precipitation is always in the associated state when the ionic strength is greater than 0·2. End-group analysis by Sanger's method[2,11] has shown that arachin has ten or eleven N-terminal groups of four species (Cater, C. W., and Ure, G. R., unpublished work). As the ε-lysine amino-groups can all be determined by the same method, presumably reaction is complete and there are ten or eleven peptide chains, linked by a method other than peptide bonds.

Arachin half-molecule. By means of high *p*H values[12], or the influence of guanidine hydrochloride[13,14], it is possible to convert arachin to a half-molecule even at very high ionic strengths. The process does not stop at the half-molecule stage, but further breakdown to very slowly sedimenting material occurs. In the case of high *p*H values (sodium hydroxide), the formation of the half-molecule is irreversible; but in the case of guanidine hydrochloride, the reaction is at least partially reversible, since some of the parent molecule is re-formed after removal of the guanidine hydrochloride by dialysis.

Diffusion measurements indicated that the low ionic strength half-molecules were more asymmetric than the parent molecule, the axial ratios being 4·5 and 2·6, respectively[9]. This change in asymmetry

Table 1. END-GROUP RESULTS FOR ARACHIN AND DENATURATION PRODUCTS

Protein fraction	Mean mol. wt. per N-terminal group	Free α-amino-groups per arachin molecule (mol wt. = 330,000)			
		Glutamic acid	Glycine	Leucine	Valine
Native arachin	32,000	2	3–4	3–4	2
Half-molecule	34,000	2	3–4	3–4	2
Sub-units	29,000	2	4	3–4	2
Further breakdown (sod. hydrox.)	16,000	2	5	7	6
Further breakdown (urea)	17,000	2	5	6	5

is not confirmed by viscosity measurements, since only a very small increase in viscosity occurs on lowering the ionic strength. Similarly, only a slight rise in viscosity occurs on formation of the half-molecule via guanidine hydrochloride, part of which might be caused by breakdown to the sub-unit stage[14]. It is difficult to reconcile these viscosity results with the diffusion data.

By adjusting the pH value and ionic strength carefully, it is possible to isolate the half-molecule in a fairly pure state[13]. The number and nature of the N-terminal groups are the same as those of the parent molecule (Table 1). Although it cannot be stated definitely that the splitting of the arachin molecule by high pH produces the same halves as are produced by simpler dissociation (in view of the irreversibility there must be some difference in the reaction), yet the splitting with high pH produces no new N-terminal groups. It is not practicable to determine the N-terminal residues of half-molecules produced at low ionic strength without causing association.

In view of the conflicting results obtained by diffusion and viscosity regarding the relative asymmetry of the half-molecule, it is not possible to decide definitely whether the cleavage is longitudinal or transverse; it does not, however, cut across peptide chains. There is little evidence that the two half-molecules are different; they have the same sedimentation constant. Quantitative N-terminal estimates, resulting in odd numbers of certain species, suggest that they may be different. A better explanation of this phenomenon, however, for which other evidence is available (see ref. 12 and unpublished work by Cater, C. W., and Ure, G. R.), is that two (or more) arachins exist, and these are indistinguishable in almost all physical properties.

Sub-unit stage. In the simple dissociation of arachin by lowering the ionic strength of a solution, only half-molecules are produced. In the case of treatment at high pH or by guanidine hydrochloride, however, the reaction does not stop at the half-molecule stage; further molecular breakdown occurs giving very slowly sedimenting material[14]. There is no evidence to show that this change can be reversed. The low-molecular weight material is precipitated at first (*vide infra*) on removal of the alkali or guanidine salt by dialysis to the original conditions of pH and ionic strength. No intermediate stages are found between the half-molecule and the sub-units. The considerable increase in viscosity increment which accompanies the formation of the sub-units[14,15] indicates the asymmetrical character of the denatured molecules. The extent of the viscosity increase is greater as the concentration of denaturant is increased.

Unlike denaturation with guanidine salt or alkali, urea denaturation does not give any trace of half-molecules in sedimentation experiments. Arachin is changed directly to sub-units[8]. It is apparent, therefore, that the bonds holding the sub-units together are not stronger than the bonds holding the half-molecules together with respect to resistance to urea. End-group analysis of the low-molecular weight material produced by controlled denaturation with sodium hydroxide indicates a molecular weight/N-terminal ratio of about 30,000. This is in reasonable agreement with sedimentation and osmotic pressure measurements (Naismith, W. E. F., unpublished work), and leads to the conclusion that the sub-units are probably single polypeptide chains. Further, the N-terminal residues found are quantitatively in agreement with those of both intact arachin and the half-molecule (Table 1). Clearly no peptide links have been broken up to this stage, although the molecular weight has been reduced ten- or eleven-fold.

Assuming a molecular weight for arachin of 330,000, a partial specific volume of 0·72, 30 per cent hydration and an axial ratio of 4·8 (based on the viscosity increment using Simha's equation for prolate ellipsoids), the dimensions of the molecule considered as a prolate ellipsoid are 260 A. × 54 A. From the viscosity increments of arachin denatured to its sub-units (molecular weight 30,000) in sodium hydroxide (Naismith, W. E. F., unpublished work), urea and guanidine hydrochloride[15], the dimensions shown in Table 2 were obtained.

Table 2. DIMENSIONS OF DENATURED ARACHIN FROM VISCOSITY DETERMINATIONS

Denaturant	Axial ratio	Dimensions (A.)
pH 11·8	9·5	184 × 19
4·7 *M* urea	11·1	204 × 18
7·2 *M* urea	13·2	230 × 17
4 *M* guanidine hydrochloride	15·3	251 × 16

In view of the fact that in no case is the length of the sub-unit as great as that of the parent molecule, it is probable that the separation of the sub-units which occurs on denaturation is accompanied by some degree of unfolding of the molecule, the extent of this unfolding depending on the nature and concentration of the denaturant.

Further breakdown of sub-units. When arachin is exposed to the action of urea and then dialysed against buffer in which the protein is normally soluble, to remove the denaturant, precipitation of the denatured material occurs, the proportion of precipitate increasing with time as denaturation proceeds. The precipitate contains nothing of higher molecular weight than sub-units. A maximum of insoluble material is reached, after which solubilization occurs progressively until no precipitation is found after prolonged exposure (for example, 500 hr. in 4·7 *M* urea at an ionic strength of 0·15). Similar results have been observed with sodium hydroxide. Measurements of osmotic pressure show a progressive decrease in average molecular weight with solubilization to about 20,000, until solute penetration of the osmometer membrane occurs. At the same time the viscosity decreases and the molecular weight/N-terminal ratio falls, both in alkaline and urea systems, to a value of 16,000–17,000. Thus, only at this late stage in the course of denaturation, peptide links seem to be broken and new N-terminal residues appear (see Table 1). It is a reflexion on the specificity of the entire system that very little random splitting occurs, and the new N-terminal residues are increased quantities of three of the four residues found in native arachin, in spite of the fact that these particular residues are not notably abundant in arachin.

With guanidine hydrochloride denaturation, the resolubilization phenomenon does not occur[8]. Apparently the sub-units are the ultimate products of the action of the guanidine salt. In no case, whether guanidine salts, alkali or urea are employed, is there at any time complete insolubilization during denaturation. This may indicate that a small part of the molecule is essentially different from the rest in that it never becomes insolubilized on denaturation.

The nature of the bonds between the half-molecules and the sub-units is not known. Labile peptide links are not involved; but salt-links, hydrogen bonds and possibly disulphide links are involved[1]. The difference in the behaviour of half-molecules in urea solution compared with other systems suggests that there is more hydrogen-bond character in the bonds between sub-units than in the bonds between half-molecules. The latter may have more of a salt-like character, in line with the dissociation at low ionic strength. The role of cystine has not been satisfactorily explained. Oxidation of the disulphide links by recognized methods involves some denaturation, but is difficult to attain completely. Alkaline denaturation involves the destruction of most of the cystine in the protein.

It seems probable, then, that arachin consists of two bundles of about five sub-units. The two halves are joined by very weak links. The sub-units are single chains, folded in the native protein and half-molecule, which may be reasonably parallel as in other globular proteins. They are linked in a fashion which not only necessitates that all of them are liberated simultaneously, but also that they become free to unfold at the same time. At this stage, and not before, the protein can form fibres[16].

SOME RECENT ADVANCES IN THE IDENTIFICATION OF LEUCO-ANTHOCYANINS AND THE CHEMISTRY OF CONDENSED TANNINS

By DR. DAVID G. ROUX

Leather Industries Research Institute, Rhodes University, Grahamstown, South Africa

SINCE the first recognition of leuco-anthocyanins and their wide distribution by the Robinsons[1], the method of recognizing this general class of compounds has improved considerably with the use of paper chromatography. Bate-Smith[2] was the first to use this technique for identifying the anthocyanidins formed from leuco-anthocyanins conforming mainly to the delphinidin and cyanidin types, and I have recently extended[3] the method to include the recognition of leuco-anthocyanins, and also of 2 : 3-dihydroflavonols, with different patterns of hydroxylation.

Bate-Smith's (*loc. cit.*) conditions of generation of the anthocyanidins from plant tissues by heating on a water-bath with 2 *N* hydrochloric acid, although entirely satisfactory for illustrating the remarkably widespread distribution of the leuco-compounds, is less suitable for certain plant extracts. Thus, in the presence of an excess of other flavonoid polyphenols, simultaneous formation of phlobaphene occurs, and the red colour of the anthocyanidin formed is not only partly or wholly obscured in solution, but is also often difficult to detect on paper chromatograms due to interference caused by a brown phlobaphene streak. Improved conditions for generating anthocyanidins from such plant extracts were developed by Pigman *et al.*[4] by using hydrochloric acid in wet *iso*-propanol solution under pressure. At present this represents the most satisfactory method, as formation of phlobaphene in the presence of hydrochloric acid appears to be kept at a minimum due to the limited accessibility of oxygen, and the best conditions for formation of anthocyanidin are maintained.

A new step has now been taken which renders possible the direct and easy recognition of leuco-anthocyanins, and which excellently supplemented the use of the above methods. This involves the use of toluene-*para*-sulphonic acid as chromogenic reagent in conjunction with two-dimensional paper chromatography run under specific conditions. The plant extract under investigation is spotted on to a two-way paper sheet and the chromatogram developed in water-saturated *sec.*-butanol or butanol/acetic acid/water (4 : 1 : 5) for direction 1, and water only, or preferably aqueous 2 per cent acetic acid[5], in direction 2. After final drying, the chromatograms are evenly sprayed with 3 per cent toluene-*p*-sulphonic acid in ethanol, and heated at 103° C., usually for 5–10 min., until colour development occurs.

Leuco-anthocyanins of unknown and probably complex structure, usually of low to medium R_F in direction 1 and of low R_F in direction 2, give red colorations. Flavan-3 : 4-diols (for example, 7,8,3′,4′-tetrahydroxyflavan-3 : 4-diol[6], 7,3′,4′,5′-tetrahydroxyflavan-3 : 4-diol[7], 5,7,3′,4′-tetrahydroxyflavan-3 : 4-diol[8] and 7,3′,4′-trihydroxyflavan-3 : 4-diol[9]) of low to medium R_F in direction 1 and medium R_F in direction 2 (see Table 1) give pink to scarlet spots, depending on the anthocyanidin formed. Flavones and flavonols, due to their planar structure[5,10], do not migrate in direction 2 with water as developing agent and are often visible in ordinary or in ultra-violet light on the starting line; but 2 : 3-dihydroflavonols (for example, dihydrorobinetin, dihydrofisetin (fustin) and dihydroquercetin (taxifolin)) migrate in direction 2 and develop from colourless into yellow fluorescent spots visible under ultra-violet light due to their conversion into the corresponding flavonols under the acid conditions[11]. Taxifolin eventually assumes a brownish colour under ultra-violet light. Catechins (for example, *d*-gallocatechin, *d*-catechin and *dl*-epi-7,3′,4′-trihydroxyflavan-3-ol[12]) develop prominent brown spots in visible light, which appear deep blue-mauve under ultra-violet light. Monomeric polyhydric phenols give yellow (resorcinol), blue (catechol) or reddish spots (phloroglucinol) due to their reaction with glucose resulting from acid hydrolysis of the paper[13]. This simple spray-reagent is therefore excellent for diagnostic use, particularly in the flavonoid field, where the identification of leuco-anthocyanins has excited much interest recently.

In order to illustrate the use of the method the following materials were examined. A two-way chromatogram of the methanolic extract of the heartwood of *Acacia melanoxylon* sprayed with toluene-*p*-sulphonic acid reagent develops two leuco-compounds in close proximity, in approximately equimolecular concentration, having the same shade of red ($\lambda_{max.}$ = 540 mμ), and giving similar blue colorations ($\lambda_{max.}$ = 590 mμ) with aluminium sulphate[14] (compare Table 2). These differ in R_F in direction 1 (see Table 1), and by analogy to the work of Roberts[15] on the catechins this suggests that geometrical isomers are present in the amorphous melacacidin (7,8,3′,4′-tetrahydroxyflavan-3 : 4-diol) identified by King and Bottomley[6].

Similarly, a two-way chromatogram of the methanolic extract of the heartwood of *Acacia mollissima* (black wattle) develops a light pink spot ($\lambda_{max.}$ = 525 mμ) plus a faint pink 'cloud' trailing in advance in direction 1. These represent the compound 7,3′,4′-tetrahydroxy-flavan-3 : 4-diol recently characterized by Keppler[8]. This monomeric leuco-compound is also present in the heartwoods of *Acacia decurrens* (green wattle), *Acacia dealbata* (silver wattle) and *Acacia pycnantha* (golden wattle).

To examine the scope of the method in dealing with unknown materials, eight different hardwoods commonly used for flooring purposes in South Africa were examined as above. Two of these, African rosewood (*Copaifera tessmanii*) and mucibe (*Copaifera coleosperma*) from west and tropical Africa, were found to contain highly mobile and differing leuco-compounds. These were isolated and appear to be of the monomeric flavan-3 : 4-diol type. Their presence is characterized by a number of pink and red spots of medium R_F in the water direction. From this the distribution of these 4-hydroxycatechins in the heartwoods of trees appears to be fairly general among certain genera of the order Leguminosae. Other leuco-anthocyanins of unknown identity in the low R_F region (direction 2) were shown up in chromatograms of the extractives of Rhodesian teak (*Baikiaea plurijuga*) and messanda (*Erythrophleum guineense*) as continuous broad red streaks covering a relatively large area. Brown and yellow spots developed on various chromatograms, and in one instance, Burma teak (*Tectona grandis*), the major constituent developed a pale blue coloration.

More specifically, these methods were applied to chromatograms of black wattle (from the bark of *Acacia mollissima*) and quebracho (from the heartwood of *Schinopsis balansae*) extracts, both used extensively for commercial tannage. The method of Pigman *et al.*[4], and more diagnostically the toluene-*p*-sulphonic acid spray, both indicate the presence of leuco-anthocyanins in relatively high concentration in each extract. This contrasts with the findings of King and White[16], who claimed the absence of leuco-anthocyanins from these extracts.

In the case of quebracho, the monomeric leuco-fisetinidin 7,3′,4′-trihydroxy-flavan-3 : 4-diol[8,9] has been shown to be absent from the extract by means of paper chromatography, although the extract as a whole yields fisetinidin[9]. On heating a two-way chromatogram of quebracho extract, sprayed with toluene-*p*-sulphonic acid, an intense pink coloration ($\lambda_{max.}$ = 523 mμ) turning blue ($\lambda_{max.}$ = 545 mμ) with aluminium sulphate develops in the lower R_F region. Fractionation of the extract further confirmed that these were leuco-fisetinidins of lower R_F (mainly concentrated at R_F = 0·21, 0·25, 0·28) than the above monomeric flavan-3 : 4-diol (R_F = 0·49) in the water direction. They are represented as a broad pink band leading to the origin and coinciding exactly in distribution with those main polyphenolic constituents of the extract which have strong reducing properties. Although the synthetic catechin, *dl*-epi-

Table 1. R_F VALUES OF FLAVAN-3 : 4-DIOLS

Flavan-3 : 4-diol	*sec.*-Butanol	2 per cent acetic acid

	0·38	0·54
5,7,3′,4′-Tetrahydroxy-	0·52*	0·50*

* Run in *n*-butanol/acetic acid/water and water only, respectively (Swain, T., private communication).

Table 2. ABSORPTION MAXIMA OF ANTHOCYANIDINS AND THEIR ALUMINIUM COMPLEXES EXAMINED ON PAPER CHROMATOGRAMS

Anthocyanidin	$\lambda_{max.}$ (mμ)	$\lambda_{max.}$ (mμ) of aluminium complex	Δλ*
Delphinidin	555	580	25
Cyanidin	545	560	15
Pelargonidin	520	no complex	
Robinetinidin	532	570	38
Fisetinidin	525	545	20
3 : 7 : 4′-Trihydroxyflavylium chloride	485	no complex	
3 . 7 . 8 . 3′ : 4′-Pentahydroxyflavylium chloride	540	590	50

* Delphinidin and robinetinidin, containing pyrogallol nuclei, were found to co-ordinate more readily on paper sheets with aluminium salts than cyanidin and fisetinidin, containing catechol nuclei. This stronger co-ordination is probably responsible for the larger shifts recorded for the former, compared with the latter group of anthocyanidins. The abnormally large shift for 3 7.8.3′.4′-pentahydroxyflavylium chloride, with its two pairs of vicinal hydroxy groups, was first recorded by Bottomley (ref. 22).

7,3′,4′-trihydroxy-flavan-3-ol, regarded by Freudenberg and Maitland[12] as a probable 'precursor' of quebracho extract, was similarly found not present in the extract in any appreciable proportion, the foregoing work confirms their concept of the flavonoid nature of the constituents, and also shows that the pattern of phenolic hydroxylation of a large percentage of the polyphenols is identical to that of the synthetic 'quebracho-catechin'.

For black wattle extract, areas corresponding to the major polyphenolic constituents *A*, A_1, *C* and *E* and the low R_F trail (see ref. 17) give an intense scarlet coloration with toluene-*p*-sulphonic acid spray, while constituents *B* and *C* develop brown colorations. This reaffirms evidence obtained by laboriously fractionating the exceptionally complex polyphenolic mixture and studying the reaction of each fraction by using the method of Pigman *et al.*[4].

Robinetinidin, or 3,7,3′,4′,5′-pentahydroxy-flavylium chloride[7] ($\lambda_{\max} = 532$ mμ), has now been developed in relatively high proportion from black wattle constituents A_1, *C* and *E* and in minor concentration from constituent *A*. Fisetinidin ($\lambda_{\max.} = 524$ mμ) also forms in relatively high proportion from constituent A_1, and a prominent orange-coloured compound ($\lambda_{\max.} = 470$ mμ) with the same R_F as synthetic 3,7,4′-flavylium chloride ($\lambda_{\max.} = 485$ mμ) results simultaneously from each of the constituents A_1, *C* and *E*. Similar, if not identical leuco-anthocyanins, yielding robinetinidin, fisetinidin and the unidentified pigment, are present in green (*A. decurrens*), silver (*A. dealbata*) and golden (*A. pycnantha*) wattle bark extracts. This represents the first occasion on which the presence of a leuco-robinetinidin has been demonstrated in Nature, and the proportions of robinetinidin and fisetinidin generated correspond to those of trimethoxygallic and veratric acids obtained from improved conditions of permanganate oxidation of methylated wattle tannins[18].

The leuco-robinetinidins and leuco-fisetinidin of black wattle extract have much lower R_F values in the water direction than their established monomeric flavan-3 : 4-diol counterparts (compare Tables 1 and 3).

This suggests the possibility that the leuco-anthocyanins present in wattle extract may possess a greater degree of structural complexity than the corresponding monomers, although the flavonoid structure obviously remains intact. Evelyn[19] has shown that the mobile fraction of wattle extract, also containing a low proportion of *d*-catechin and possibly *d*-gallocatechin[17], has a molecular weight of 620, reflecting a dimeric structure for the majority of flavonoid compounds present.

Furthermore, those polyphenols of wattle extract which remain completely immobile in water on cellulose sheets form the same anthocyanidins, for example, robinetinidin (high proportion) and fisetinidin (low proportion), as the mobile leuco-anthocyanins. This very low R_F fraction must be polymeric, as the average molecular weight of the total polyphenolic wattle fraction is[20] about 1,270. The simple units of the extract, therefore, undergo biochemical condensation to form higher molecular-weight polymers, which are present even in the youngest barks which may be stripped from *Acacia mollissima*[21].

Table 3. R_F VALUES OF BLACK WATTLE LEUCO-ANTHOCYANINS AND THE ANTHOCYANIDINS FORMED FROM EACH CONSTITUENT

Black wattle constituent	Water-saturated sec.-butanol	2 per cent acetic acid	Anthocyanidin generated
E	0·38	0·21	Robinetinidin
C	0·49	0·22	Robinetinidin
A_1	0·55	0·26	Robinetinidin Fisetinidin
A	0·68	0·29	Robinetinidin (trace)

These immobile leuco-anthocyanins and also the low R_F leuco-anthocyanins A_1, *C* and *E* of black wattle extract have high affinity for collagen in aqueous medium[16], and form that fraction of the extract part of which is 'irreversibly' fixed to the collagen after commercial tannage (unpublished work). These leuco-anthocyanins may, therefore, be regarded as true tannins.

As toluene-*p*-sulphonic acid has replaced hydrochloric acid[8] in the vanillin–hydrochloric acid chromatographic spray reagent for phloroglucinol and for detecting phloroglucinol nuclei in flavonoid structures, it is evident from the above work that the pink-mauve colour developed by the vanillin–toluene-*p*-sulphonic acid reagent is not specific for phloroglucinol nuclei in extracts where leuco-anthocyanins are present.

Although the colorations produced by toluene-*p*-sulphonic acid spray are not specific in all instances (for example, the pink developed with phloroglucinol), its use, with adequate experience, is nevertheless a powerful tool in locating flavonoid compounds of specific structure. Its application in the work outlined above has reflected on the phlobaphene–leuco-anthocyanin–tannin relationship; on Freudenberg's concept of a catechin-'precursor' for quebracho-extracts[12]; on the presence of new leuco-anthocyanins in extracts used for commercial tannage; on the stereo-chemistry of flavan-3 : 4-diols, and on their distribution in Nature.

Thanks are due to Mr. S. P. Sherry, Wattle Research Institute, Pietermaritzburg, for authentic heartwoods of black, green and silver wattles; also to the Director of Forestry, Forest Products Institute, Pretoria, for information regarding the botanical identity of hardwoods. I acknowledge the annual grant of the South African Wattle Growers' Union to the Leather Industries Research Institute.

The Clock Paradox in Relativity

IN the course of reasoning on this subject with some of my more recalcitrant friends, I have come across a numerical example which I think makes the matter easier to follow than would any mathematical formulæ, and perhaps this might interest some readers of *Nature*.

There is no doubt whatever that the accepted theory of relativity is a complete and self-consistent theory (at any rate up to a range of knowledge far beyond the present matter), and it quite definitely implies that a space-traveller will return from his journey younger than his stay-at-home twin brother. We all of us have an instinctive resistance against this idea, but it has got to be accepted as an essential part of the theory. If Prof. H. Dingle should be correct in his disagreement, it would destroy the whole of relativity theory as it stands at present.

Some have found a further difficulty in understanding the matter. When two bodies are moving away from each other, each sees the occurrences on the other slowed down according to the Doppler effect, and relativity requires that they should both appear to be slowed down to exactly the same degree. Thus if there are clock-dials on each body visible from the other, both will appear to be losing time at the same rate. Conversely, the clocks will appear to be gaining equally as they approach one another again. At first sight this might seem to suggest that there is an exact symmetry between the two bodies, so that the clock of neither ought in the end to record a time behind that of the other. The present example will show how this argument fails.

In order to see how a time-difference will arise, it suffices to take the case of special relativity without complications from gravitation. Two space-ships, S_0 and S_1, are floating together in free space. By firing a rocket S_1 goes off to a distant star, and on arrival there he fires a stronger rocket so as to reverse his motion, and finally by means of a third rocket he checks his speed so as to come to rest alongside S_0, who has stayed quietly at home all the time. Then they compare their experiences. The reunion of the two ships is an essential of the proceedings, because it is only through it that the well-known difficulties about time-in-other-places are avoided.

The work is to be so arranged that it can be done by ordinary ships' navigators, and does not require the presence in the crews of anyone cognizant of the mysteries of time-in-other-places. To achieve this, I suppose that the two ships are equipped with identical cæsium clocks, which are geared so as to strike the hours. On the stroke of every hour each ship sends out a flash of light. These flashes are seen by the other ship and counted, and they are logged against the hour strokes of its own clock. Finally the two logs will be compared.

In the first place it must be noted that S_1's clock may behave irregularly during the short times of his three accelerations. This trouble can be avoided by instructing him to switch the clock off before firing his rockets, and only to start it again when he has got up to a uniform speed, which he can recognize from the fact that he will no longer be pressed against one wall of his ship. The total of his time will be affected by this error, but it will be to the same extent whether he is going to the Andromeda Nebula, or merely to Mars. Since the time that is the subject under dispute is proportional to the total time of his absence, this direct effect of acceleration can be disregarded.

I choose as the velocity of S_1's travel $v = \frac{4}{5}c$, because in this special case there are no tiresome irrationalities to consider. I take the star to be 4 light-years away from S_0. The journey there and back will therefore take 10 years according to S_0. Immediately after the start each will observe the other's flashes slowed down by the Doppler effect. The formula for this in relativity theory is $\sqrt{(c+v)/(c-v)}$, which in the present case gives exactly 3. That is to say, each navigator will log the other's flashes at a rate of one every three hours of his own clock's time. Conversely, when they are nearing one another again, each will log the other's flashes at a rate of three an hour.

So far everything is perfectly symmetrical between the ships, but the question arises, for each ship respectively, how soon the slow flashes will change over into fast ones. First take the case of S_1. During his outward journey he will get slow flashes, but when he reverses direction at the star, they will suddenly change to fast ones. Whatever his clock shows at this time it is certainly just half what it will show when he gets home. Thus for half the journey he will get flashes at a rate of $\frac{1}{3}$ per hour, and for the other half at a rate of 3 per hour. The average for the whole journey will thus be at a rate $\frac{1}{2}\left(\frac{1}{3}+3\right)=\frac{5}{3}$ per hour. During this time S_0 will have sent out 10 years' worth of flashes, and so in the end S_1's clock will record $\frac{3}{5}\times 10 = 6$ years, which, of course, he can verify directly from his detailed log.

S_0's log will be quite different. He will start with slow flashes and end with fast ones, but the change-over is determined by S_1's reversal, which is occurring 4 light years away from him. Consequently, he will get slow flashes for $5+4=9$ years, and therefore fast flashes for only 1 year. The total number he will count is $\frac{1}{3}\times 9+3\times 1=6$ years' worth. His nine years of slow flashes and one of fast are in marked contrast with S_1's experience of three years of each. Thus when the navigators compare their logs together they will be completely different, but both will agree that S_0's clock went for ten years and S_1's for only six.

It may be that S_0 will suggest that for some reason S_1's clock was going slow during the motion, but S_1 will point out that there was no sign of anything wrong with it, and that anyhow his heart-beat and other bodily functions matched the rate of his clock, and he may even direct attention to the fact that his forehead is perceptibly less wrinkled than that of his twin brother. In fact—as the relativist knows—he is now actually four years younger than his brother.

In giving this example, I have assumed S_0 at rest for the sake of simplicity, but it is not hard to verify that the two logs will be exactly the same if a uniform motion of any amount is superposed on the system. However, to show this would go beyond the scope of this communication.

X-Ray Study of Scarbroite

VERNON, in 1829[1], first described scarbroite as a soft white aluminous substance filling veins in a sandstone occurring on the Scarborough coast, but did not give properties sufficiently distinctive to identify the mineral with certainty. Since then, few reports on it have been published, although the American Petroleum Institute Research Project No. 49 on clay minerals[2] lists the substance, and surmises that it consists of a mixture of clays. We have examined similar material from the same locality and environment, and conclude that it is identical with Vernon's scarbroite, but a preliminary X-ray study provides evidence that it exists as a mineral in its own right.

Our specimens were obtained from vertical fissures in the sandstone in South Bay, Scarborough, and in appearance are white, fine-grained and compact, but quite soft and in many cases damp and easily crumbled. Spectrographic and chemical analyses show that the principal constituent is aluminium, with only traces of other ions: while silica is certainly present, X-ray photographs show that it must be largely in the form of free quartz. Although a full quantitative analysis remains to be carried out, it seems likely, therefore, that the material is a highly hydrated aluminium oxide. The specific gravity is approximately 1·85 and the mean refractive index 1·509; the material does not yield single crystals large enough for other optical measurements.

Scarbroite is sufficiently fine-grained in its natural state to give continuous X-ray powder lines which are even fairly diffuse on some photographs. An X-ray powder pattern of a typical specimen is given in Table 1, the photograph being taken with monochromatized cobalt K_{α}-radiation on a Guinier-type transmission camera of effective diameter 22·9 cm. The intensities are estimated visually.

5	3·96	4	2·554		

(b) = broad

Different specimens of the material show slight variations from this pattern, which may be due both to the presence of small quantities of other materials and to the co-existence of different states of hydration. The pattern can be indexed tentatively on the basis of a primitive rhomb-based hexagonal cell with a = 34·5 A. and c = 17·3 A., the 8·64 A. reflexion being 0002.

Specimens heated to 120° C. for two days in air or dehydrated over phosphorus pentoxide for three weeks show minor changes in their powder patterns which can be interpreted as due to a small reduction in the c-axis. On heating to 130°–140° C. in air for several days, a completely different pattern is obtained which again can be indexed on the basis of a hexagonal cell with a = 31·0 A., c = 12·8 A. Heating to higher temperatures causes the X-ray reflexions to become more diffuse and progressively fainter, while the c-axis shrinks considerably, the lowest recorded value being 11·3 A. at 228° C. At temperatures higher than this, heating for two days or more causes the crystallites to break down completely, no X-ray powder pattern being obtained. At 900° C. a very diffuse pattern of γ-Al_2O_3 emerges.

Further study of the mineral is in progress.

Velocity of Compressional Waves for a Stratigraphic Profile of Chalk at Flamborough, Yorkshire

A LABORATORY determination has been made of the velocity of compressional waves in a stratigraphic section of the Chalk at Flamborough, Yorkshire. The Chalk ranges from Cenomanian to Senonian in age, and a thickness of about 378 metres is seen in the fine exposures around Flamborough Head[1]. Thirty samples were collected, at twelve stations distributed throughout the section, representative samples being chosen at each station. These were kept moist after collection and the very small amount of included air removed by saturation in a vacuum. The velocity

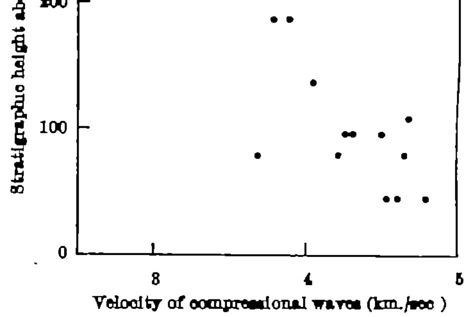

Fig. 1. The velocity of compressional waves for a stratigraphic profile of Chalk at Flamborough

measurements were made on the fresh rock samples at room temperature and pressure.

The results of these determinations and the stratigraphic level above basal (red) Chalk are shown graphically in Fig. 1. At the bottom of the section the velocity of compressional waves reaches almost 5 km./sec., while at the top it is a little more than 3 km./sec. The velocity changes linearly with depth and the velocity gradient is about 5 sec.$^{-1}$. These velocities are considerably greater than those given for Chalk in the south of England[1], but can be matched in north-west Germany[2]. There is no mention of an appreciable velocity gradient in the Chalk of southern England, and even in north-west Germany the value is less than 2 sec.$^{-1}$.

A fuller account of this, together with related work, will be published elsewhere.

A Simple Method of determining Ultrasonic Velocities in Rocks

We have devised a simple method of determining elastic constants of rocks which is based on the principle of the critical angle method employed by Schneider and Burton[1]. In this method a narrow beam of ultrasonic waves strikes the rock section immersed in a liquid at right angles to its axis of rotation, and the critical angles θ_l and θ_t for total reflexion of the longitudinal and transverse waves set-up in the section are determined experimentally. Knowing the velocity of ultrasonic waves V in the liquid, the velocities of longitudinal and transverse velocities V_l and V_t in the rock section are determined by using the familiar relations,

$$V_l = V/\sin\theta_l\,;\quad V_t = V/\sin\theta_t$$

The experimental arrangement consists of a 2½-in. brass ultrasonic cell having two holes of ⅞ in. diameter on two opposite faces. Two identical silvered quartz X-cut plates of 1¼ in. diameter and 1·1 Mc./sec. fundamental frequency are clamped against the holes from outside and serve as sender and receiver crystals. They are completely shielded by metal enclosures having provisions for making connexions to the crystals by shielded cables. One of the crystals which serves as the ultrasonic generator is connected to a completely shielded variable frequency oscillator giving a radio-frequency output of 150 volts while the other is connected across the input of a sensitive vacuum tube voltmeter. The silvered surfaces of the crystals which are kept pressed against the brass cell are at ground potential and serve effectively as shields preventing direct pick-up of the oscillator voltage by the voltmeter. The cell is filled with water or any other liquid and the oscillator is tuned to the fundamental frequency of the crystal by adjusting for maximum deflexion in the voltmeter. The rock section, which is in the form of a rectangular plate of approximate dimensions 2 in. × 1½ in. × 1/5 in., is clamped to a slow-motion rotation arrangement having a gear reduction ratio of 50 : 1 and is immersed vertically in the liquid in the cell so that it intercepts the direct ultrasonic beam from the transmitter to the receiver. Each division of the vernier scale of the rotation arrangement corresponds to an angle of rotation of 4·3′. A levelling arrangement is provided so as to adjust the axis of rotation of the section to be perpendicular to the direction of propagation of the ultra-sonic waves. By noting the four positions showing sharp dip in transmission energy on either side of normal incidence, the values of θ_l and θ_t are experimentally determined and the velocities are calculated in the usual manner. The method was first tested by determining velocities of sound propagation in some common metals. Sound velocities in some difficult types of Indian rock materials, some of which are porous and water absorbing, were determined by this method after giving a coating of collodion film, and the values are presented in Table 1. Check measurements on glass and metal plates have shown that the values are not affected by the thin film of collodion.

Table 1

Specimen	Density (gm./c.c.)	θ_l	θ_t	V_l (m./s.)	V_t (m./s.)
Khondalite	2·36	20° 0′	50° 24′	4,415	1,960
Schale	2·78	15° 7′	50° 5′	5,790	1,970
Barakar Sandstone	2·66	17° 3′	50° 5′	5,152	1,970
Red ochre*	3·52	21° 15′	48° 4′	4,166	2,034
Talc chlorite schist.*	2·82	14° 11′	47° 30′	6,156	2,048
Chalk*†	1·67	17° 38′	35° 40′	3,038	1,577
Kaolin*†	1·62	17° 0′	33° 42′	3,115	1,640

* Coated with collodion. † Tank liquid carbon tetrachloride.

Ultrasonic velocities for most of these rocks have not been determined before. It is interesting to note that in some of the materials like chalk and kaolin, for which transverse sound velocity is nearly as low as that of water, carbon tetrachloride has to be used as the tank liquid in order to ensure that the critical angle is not close to 90°.

The method presented here has the unique advantage, particularly for the determination of elastic constants of rocks, of being most simple, rapid and sufficiently accurate. There is no difficulty either in the preparation of the specimen as the thickness need not be uniform.

Chemical Shifts in $C_5H_5^-$ and $C_7H_7^+$ Ions: the Free Electron Model

In an earlier communication[1], the classical free electron model proposed by Pople[2] was modified and successfully applied to the description of the nuclear resonance spectra of hydrocarbons containing six-membered aromatic rings. It was then noted that results on a five-membered aromatic ring did not appear to be in good agreement with this theory. We now wish to report complete data on the aromatic systems $C_5H_5^-$ and $C_7H_7^+$ (cyclopentadienide ion and tropylium ion, respectively), and to compare them with theoretical expectations. The aromaticity of these two species is generally accepted[2-5].

An approximately 1 *M* solution of sodium cyclopentadienide in tetrahydrofuran was prepared from sodium sand and freshly distilled tetrahydrofuran, using methods previously described[6]. The proton resonance spectrum was observed on a Varian Model *V*–4300 *B* high-resolution spectrometer. By making successive dilutions of the stock solution (concentrations were determined by sodium analyses on a flame photometer), chemical shifts from pure water of the $C_5H_5^-$ ion were extrapolated to infinite dilution[7]. Since the 'ideality' of tetrahydrofuran as a solvent for chemical shift measurements is uncertain, we endeavoured to make measurements in other solvents such as dimethylcellosolve and dioxane. These attempts were unsuccessful, owing to insufficient solubility of the sodium cyclopentadienide. Bicyclo [2.2.1]hepta-2,5-diene (Shell Chemical Co.) was isomerized by passage through a stainless steel pipe at 485° C. The products were condensed and fractionated through a sixty-plate column to isolate cycloheptatriene (tropylidene) from toluene in about 70 per cent yield. This was further purified by fractionating in a spinning-band column at reduced pressure until a cut of very pure tropylidene ($[\alpha]_{n}^{D}$ = 1·5200) was obtained. Tropylium bromide was then prepared from this as described by Doering and Knox[5]. Its spectrum was measured and extrapolated (as above) in both aqueous and methanol solutions to which sufficient hydrogen bromide (about 0·002 *M*) had been added to suppress hydrolysis. The results are given in Table 1. In both cases the chemical shifts are relative to pure water at 25° C. and we use the same sign convention as in ref. 1.

Table 1. CHEMICAL SHIFTS (IN PARTS PER MILLION) VERSUS PURE WATER

Compound	Chemical shift	
	Observed	Calculated (see text)
$C_5H_5^-$ (Na^+)	+ 0·62 ± 0·05	+ 2·26
C_6H_6 (*a*)	+ 2·50 ± 0·05	+ 2·50
$C_7H_7^+$ (Br^-)	+ 4·67 ± 0·05(*b*)	+ 3·15

(*a*) In CCl_4, see ref. 1.
(*b*) 4·62 from OH of CH_3OH in methanol solution.

It is evident that the observed differences are much more extreme than the calculated ones, although they do agree in sign. The discrepancies are too large to be explained by solvent effects, as shown by footnote (*b*) in Table 1, and also by the fact that the benzene shift in tetrahydrofuran is +2·33. We conclude that, while the effect of the free electrons is probably present, there are other contributing factors which have to do with differences in electron density at the protons. We have attempted an empirical assessment of the effects of changing the C—C—H bond angle by measuring chemical shifts at infinite dilution in a series of cyclic mono-olefins, but without notable success as yet. We do not think it desirable to speculate further at this time, except to remark that the electron distribution in these systems is undoubtedly affected by the differences in overall charge. The Pauling "electroneutrality principle"[8] gives, perhaps fortuitously, an effect of the proper sign.

Formation of Liesegang-like Rings by Metal Ions and Chelating or Complexing Agents

IT has been recently reported from this laboratory that Liesegang-like rings of growth and inhibition of growth of bacteria were produced around filter paper disks in inoculated agar media when a chelating agent was dissolved in the agar and a metal ion was applied on the disk[1]. The formation of as many as six concentric and alternate rings of growth and absence of growth was ascribed to the presence or absence of toxic mixtures of chelating agents, metal chelates and free metal ions in the areas of the rings. These areas of interaction were invisible and apparent only through the biological response of the micro-organisms.

We have now obtained rings of chemical interactions which are visible. This has been achieved primarily by increasing the concentration of the chelating or complexing agent and selecting an agent which had the optimum chromogenic properties, solubilities and degrees of dissociations of the complexes with two different metal ions. Dithizone (diphenylthiocarbazone) and copper and zinc chlorides were found suitable.

The experimental conditions were similar in most respects to those employed for the bacteriological studies[1]. Appropriate amounts of the dithizone solution, metal salts, buffer, any other reagents under study and water were added to tubes containing 20 ml. of warm (50–55° C.) 1·7 per cent agar ('Bacto-Agar', Difco Laboratories). The contents of the tubes were then rapidly mixed and poured into Petri dishes. The agar (1·5 per cent) was allowed to harden and filter paper disks (8 mm. in diameter) were placed on the surface of the agar. Fifty µl. of the desired metal-ion/buffer mixture were then placed on the disks. The agar dishes were placed in a refrigerator (2° C.) and periodically inspected for the

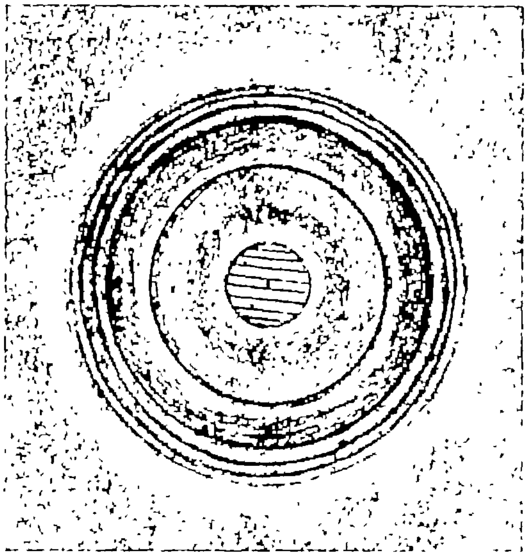

Fig. 1. Reproduction of rings produced in agar containing zinc and dithizone with copper on filter paper disk. Disk is cross-hatched

formation of rings in the agar. Representative dishes were photographed for permanent records.

Formation of multiple rings was achieved around disks containing copper (360 p.p.m. copper as the chloride in a buffer mixture of 0·012 *M* sodium phosphate and 0·012 *M* sodium citrate at *p*H 7·9) on agar containing the same buffer plus 12·5 p.p.m. dithizone and 0·2 p.p.m. zinc as the chloride. The rings were similar to Liesegang rings in that there were different coloured rings with various degrees of precipitation, together with colourless and clear rings. The colours varied from the light purple background of the zinc dithizonate in the agar to several shades of dark purple, black and brown in the rings. Varying the concentrations of the dithizone or zinc in the agar markedly affected the natures of the rings obtained, but varying the concentration of the individual buffer constituents several-fold either in the agar or on the metal disks had relatively minor effects. Fig. 1 is a reproduction of the rings obtained after five days storage at 2° C.

Interpretations of Liesegang phenomena are difficult because of the conflicting theories on the basic causes of such periodic structures[2]. The possibility that chromatographic separations of different molecular species may cause some Liesegang-like phenomena must always be considered[3]. In biological studies it is even more difficult to explain interrelationships which might be considered as forms of periodicity. Some of these may be more simply a matter of relative concentrations of biologically active materials obtained by calculated additions[4] or by diffusion[5].

Chromogenic organic complexing or chelating agents have apparently received little attention for the study of the Liesegang phenomenon. It would appear that they should offer many possibilities for this purpose as well as in the study of biological problems.

This investigation was supported in part by a grant (*E*-916) from the Division of Research Grants, U.S. Public Health Service. This communication is published with the approval of the Director as Paper No. 813, Journal Series, Nebraska Agricultural Experiment Station.

Colorimetric Determination of Vanadium

SEVERAL authors have observed that the coloured products of vanadium ions with benzhydroxamic acid[1,2] and with salicylhydroxamic acid[3] can be extracted with oxygen containing organic solvents (alcohols, ethers and esters).

It is possible to use these complexes for the colorimetric determination of vanadium. However, in using these methods in the analysis of the mineralogical products and particularly of steel, the presence of iron, titanium and uranium causes difficulties. These elements should be removed by electrolysis with a mercury cathode or by precipitation with sodium hydroxide.

During experiments with several solvents and hydroxamic acids we have now found that the reaction product of vanadium and a hydroxamic acid, for example, of salicylic acid, can be quantitatively and easily extracted with di-*iso*butylketone. By this solvent and in carefully chosen circumstances, in acidic solution, the iron, titanium and uranium complexes are not extracted.

Experimental work is now in train to develop a suitable method for the colorimetric determination of vanadium in steel, without any preliminary separation, based on the selective extraction indicated.

Molecular Vibrations and Standard Deviation of Interatomic Distances in Benzene

CLASSICAL electron diffraction studies of free molecules were limited to the determination of the geometry of molecular models that usually, for the sake of simplicity, were assumed to be rigid. By means of modern electron diffraction techniques, however, information concerning the root-mean-square deviation, u, from the equilibrium distances can readily be obtained. ($u = [\overline{(r - r_e)^2}]^{1/2}$, where r is the actual distance and r_e the equilibrium distance. In cases where asymmetric vibrations have to be considered, the distance of maximum probability might be used instead of r_e.)

The experimental determination of the values of u is based upon the study of the natural damping of the various sine-terms making up the electron diffraction intensity curve. By the visual method these natural damping factors could scarcely be obtained. The sector method, however, makes this kind of study possible. To secure reliable values all effects causing extra damping must be avoided, and the geometry of the electron diffraction apparatus must permit the study of the largest obtainable diffraction angles.

Determinations of the value of u based upon electron diffraction experiments for quite a few molecules have been reported during recent years, though the accuracy of these values is not claimed to be very large. Several molecules have been studied by I. and J. Karle, including that of benzene[1].

The important task of calculating values of u from spectroscopic data was first undertaken by the Karles[2] and by Morino *et al.*[3]. These investigations included such large molecules as carbon tetrachloride and 1.1-difluoroethylene. Dimethyldiacetylene was studied in the same way, and the results were compared with those from electron diffraction studies[4].

In the present investigation benzene has been studied. Values of u were obtained by the Oslo electron diffraction apparatus, and theoretical values were based upon the vibrational frequencies of benzene and benzene-d_6 obtained by Brodersen and Langseth[5]. The evaluation of the force constants followed the procedure of Wilson, Decius and Cross[6], and is similar to the earlier calculations of Crawford and Miller[7]. The vibrations were treated as harmonic oscillations. The results of these calculations for $T = 0$ and 298° K. are given in Table 1, together with electron diffraction data from two independent investigations conducted by us. The results earlier obtained by Karle[1] have also been included. The correspondence between our results obtained from electron diffraction studies and the spectroscopic results is very good, particularly for the C—C distances. For the C—H distances the deviation is somewhat larger. This is to be expected, as the contribution of the C—H distances to the radial distribution curve is considerably smaller than that of the C—C distances. The accuracy of the values of u depends upon the accuracy of the zero-line determination of the final radial distribution curve. The zero line is determined by an experimental 'envelope'[8] which is somewhat uncertain, particularly in the innermost region of the radial distribution curve. This is probably the reason for the rather large deviation in the case of the C—H bond distance.

Table 1. CALCULATED AND MEASURED STANDARD DEVIATION FOR INTERATOMIC DISTANCES (u) IN BENZENE

Distances (A.)	Calculated from spectroscopic data		Electron diffraction data		
	$T = 0$	298° K.	Present investigation I	II	Karle
$C_1—C_2$	0·0457	0·0459	0·0455	0·0453	0·055
$C_1—C_3$	0·0534	0·0547	0·054	0·054	0·067
$C_1—C_4$	0·0576	0·0597	0·062	0·059	0·075
$C_1—H_1$	0·0771	0·0771	0·073	0·073	0·072
$C_1—H_2$	0·1000	0·1004	0·094	0·092	0·092
$C_1—H_3$	0·0962	0·0960	0·094	0·087	
$C_1—H_4$	0·0928	0·0942	0·097	0·099	
$H_1—H_2$	0·1556	0·1561			
$H_1—H_3$	0·1312	0·1321			
$H_1—H_4$	0·1179	0·1191			

The experimental values for the H—H distances have not been included. The value for the $H_1—H_2$ distance is unobtainable from our electron diffraction results. For the $H_1—H_3$ and $H_1—H_4$ distances, values are obtained, but they are too uncertain to be included as real measured values. However, the electron diffraction results do show that the u-values for the largest two H—H distances are of the same order of magnitude as for the largest C—H distances. They further show that the value of u of the $H_1—H_3$ distance is larger than that of the $H_1—H_4$ distance, in agreement with the calculated results.

The electron diffraction values of I. Karle are, within the limits of the errors, in agreement with the calculated values, with a single exception (namely, $C_1—C_4$).

Detailed accounts of the electron diffraction studies of benzene as well as of the spectroscopic calculations will be published elsewhere[9].

A Phase Transition in Cæsium Plumbochloride

IN the course of an investigation of some cæsium-lead halide compounds, a phase transition has been observed in cæsium plumbochloride ($CsPbCl_3$). This compound may be obtained from plumbous chloride dissolved in a hot aqueous solution of cæsium chloride on cooling[1], or simply by melting or sintering cæsium chloride and plumbous chloride together in the correct stoichiometric proportion. The crystals are pale yellow and rectangular in shape. At room temperature they show birefringence under the polarizing microscope. However, on heating, the interference colours change continually and completely disappear at 46·9° C. This phenomenon is reversible; and on cooling, the interference colours appear again in the reverse order. Different types of twin formation can also be observed in these crystals; very common is twinning with (110) as the composition plane.

X-ray investigations on powders and single crystals of cæsium plumbochloride show that the form stable at room temperature is tetragonal with axes $a = 5·590$ A., $c = 5·630$ A., whereas the form stable above 46·9° C. is cubic with $a = 5·599$ A. The lattice is primitive, with one molecule per unit cell, and the structure can be described as a perovskite structure with the Goldschmidt tolerance factor $t = 0·8$, which is just on the limit of the condition for the perovskite structure to be stable. The axes of the tetragonal form have been determined as a function of temperature in the range 20–55° C. from oscillation photographs of a single crystal. Plotted against temperature, a curve is obtained which has a very strong similarity with the corresponding curve for barium titanate[2].

On the basis of intensities visually estimated from Weissenberg diagrams of a single crystal, projections of the electron densities have been calculated. As there is scarcely any difference between the intensities of the tetragonal and the cubic form, the electron projections are practically identical and show that in both cases the Cl-atoms are moved out from the positions (½, 0, 0) for an ideal perovskite structure to the positions (½, ±1/15, ±1/15) perpendicular to the edges, and that the caesium atoms at (½, ½, ½) are drawn out in directions perpendicular to the unit-cell faces. That these effects are not due to diffraction errors has been inferred from calculation of an electron projection based on intensities calculated for caesium plumbochloride with an assumed ideal perovskite structure. From the photographs taken at temperatures above and below the transition point it could be seen that the crystal was essentially a single crystal. It thus appears that from the apparent space-group symmetry alone one cannot get information about the actual mean positions of the chlorine atoms but only about their 'statistical centres of gravity'.

It seems likely that the transition at 46·9° C. is a second-order transition from complete disorder in the cubic crystal to some degree of order in the tetragonal crystal, and it is expected that a comparison with the transition in barium titanate at 120° C. may be interesting. In spite of the great similarity with the isomorphic barium titanate crystals it has not so far been possible to detect ferro-electric behaviour of the caesium plumbochloride crystals, but further investigations are in progress.

I am much indebted to Mr. V. Frank for having measured the dielectric constant of caesium plumbochloride at different temperatures.

A Lake with Trapped Sea-Water ?

WHEN examining such a large number of lakes as my collaborators and I have done since 1945 (about a hundred lakes with monthly observations during one year, mostly in southern Norway), it is inevitable that strange types of lake are sometimes encountered. One very curious find was the occurrence of sea water that must have been trapped some six thousand years ago in a part of Lake Tokke (Rørholtfjorden) in southern Norway.

It is certainly difficult to admit the possibility of sea water still being left in a lake 60 m. above the present sea-level, but the complete analysis leaves no doubt as to the water being sea water. The possibility of it being supplied by salt springs was taken into consideration, but rejected, on account

of the virtual absence of such clays as may store sea water below the ancient marine limit. Also the picture of the chlorine content is that of a stored mass being disturbed by turbulence from above, not that of salt waters being supplied to the bottom of a freshwater lake.

The topographical explanation is that the basin of Rørholtfjorden is very narrow and deep, and there is no river streaming through this part at all. There is the pronounced semi-stagnation of waters from about 80 m. to 132 m. depth, preserving the salt deep from contact with the overlying freshwater lake during periods of full circulation in the freshwater part. This semi-stagnation is brought about through turbulence removing only a very little at the top of the salt bottom waters. Indeed, from the two series of chloride observations, it should be possible to calculate the rate of wasting-away of the bottom waters still left, and the part played by diffusion.

The great difference in composition compared with the original sea water is that there is no sulphate left. It has all gone to form hydrogen sulphide and other sulphides. The bottom waters to-day smell very little of hydrogen sulphide, which can now be formed only from protein sulphur.

There are enormous quantities of methane arising from cellulose and lignin, and a very high iron carbonate content.

This lake represents the most nearly complete stagnation of bottom waters imaginable, of quite a different degree from the most stagnant of so-called meromictic lakes (Blankvatn[1]) or land-locked inlets of the sea (Framvaren[2,3]).

Through close collaboration with Prof. B. Kullenberg, of the Department of Oceanography, University of Gothenburg, extended investigations of the bottom waters and sediments are to begin during the winter 1957–58, it being easiest to operate the core samplers from the ice.

We have secured further collaboration from a number of people and institutions for isotope determinations, radioactivity, pollen, diatom and foraminifera analyses, as well as more ordinary routine work. My main reason for publishing this preliminary notice of our work (some results have been previously published[4]) is that there may be scientists wishing to collaborate, or to have material sent them from such an extraordinary locality; this can easily be arranged.

Autoradiography of Polytene Chromosomes of *Rhynchosciara angelae* at Different Stages of Larval Development

THE polytene chromosomes of Diptera, since their rediscovery in 1933 [1,2], have proved to be excellent material for cytogenetic studies. They present a longitudinal differentiation into a series of transverse bands, which were shown to be the sites of the genes[3,4]. Recently, experiments performed with Chironomidae[5–7] and Sciaridae[8,9] showed that the bands of polytene chromosomes may vary in their morphology in different cells at the same stage of larval development and in the same cell at different stages of the larval life.

Some of these bands pass through only slight modification in their morphology, while others form large bulbs ('puffs') which increase by two to three times the diameter of the chromosomes at this specific locus. As the changes in structure of these chromosomal loci occur always at the same stage of larval development, and in a definite sequence and manner, they have been interpreted as a morphological manifestation of gene activities.

To obtain fuller information on the metabolism of polytene chromosomes in relation to the morphological changes that they exhibit during larval development, we have studied, by the autoradiographic method[11], the salivary gland chromosomes of larvæ of *Rhynchosciara angelae* (Diptera, Sciaridae) injected with a precursor of deoxyribonucleic acid.

Previous work using the autoradiographic method was carried out on polytene chromosomes by Pelc and Howard[12] on *Drosophila* and by one of us (A. F.) on *Chironomus*, by means of carbon-14-labelled precursors of ribonucleic acid and proteins. Unpublished observations have led us to the conclusion that the nucleoli and the pyroninophilic bands of the chromosomes, coloured red by Unna staining and rich in ribonucleic acid, have a much higher protein metabolism than those rich in deoxyribonucleic acid. In these experiments, the salivary glands were dissected and incubated in the hæmolymph with the labelled molecule. Gross[13] has recently presented similar data concerning the ribonucleic acid metabolism of these structures.

In the present case, however, the radioisotope was administered *in vivo* to the larvæ. Quantities of 0·01–0·1 μcurie of tritiated thymidine in a saline solution were injected into each larva without any trauma or loss of radioactive material. The experiments showed that in the puffing processes, as well as in other morphological changes of polytene chromosomes, the deoxyribonucleic acid plays a very active part. As can be seen in Fig. 1, the rates of incorporation of thymidine vary considerably in different parts of the chromosomes. The sites of greatest incorporation of thymidine into the chromosome vary with the age of the larvæ, but are constant at the same stage of larval development.

Experiments undertaken with larvæ injected with tritiated thymidine 2–5 days before being killed show that a great part of the radioactive isotope is retained in the chromosomes. This would suggest that the incorporation of the thymidine represents a real synthesis of deoxyribonucleic acid rather than a mere turnover or a simple exchange of the hydrogen atoms. As this incorporation is much more evident in certain loci of the chromosomes than in others, these findings seem to be in agreement with the statement of Breuer and Pavan[9,10], namely, that there is an increase in the number of specific genes, and not of the entire chromosome, in different stages of the larval development. Tests performed using deoxyribonuclease and ribonuclease confirmed that the tritiated thymidine was really acting as a specific precursor of the deoxyribonucleic acid.

Other experiments are now being made, using other tracers, to study the metabolism of ribonucleic acid and proteins in the polytene chromosomes of *R. angelae* during larval development.

We conclude from our investigations that the great incorporation of tritiated thymidine in loci responsible for the puffing processes of polytene chromosomes of *R. angelae* shows that deoxyribonucleic acid plays a very active part in the puffing.

There are loci of the polytene chromosomes which, although rich in deoxyribonucleic acid, show only a very little, if any, thymidine incorporation at some periods of larval development. This suggests that the corresponding gene is practically inactive at these stages of the larval life. In other stages, however, these loci are very active, as shown by their incorporation of thymidine.

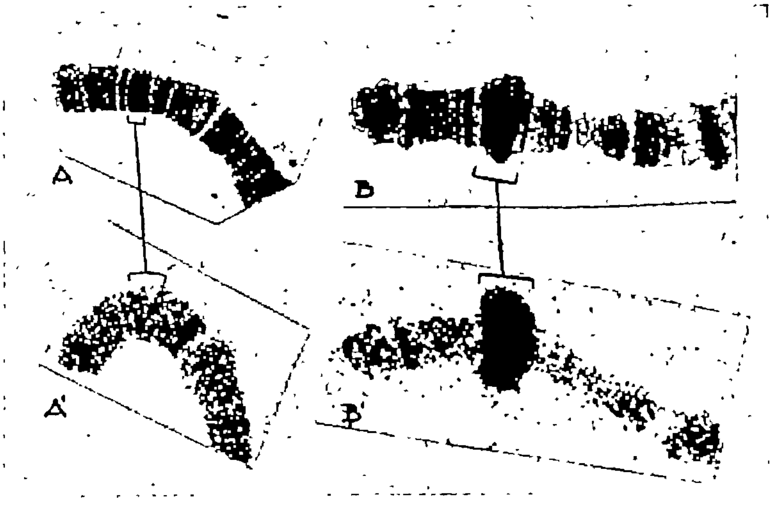

Fig. 1. Distal end of chromosome *C* of *R. angelae* at two different stages of larval life. *A* and *B*, stained by aceto-orcein; *A'* and *B'*, the corresponding segment radioautographed without any staining. *A* and *A'* are from a full-grown larva; *B* and *B'* are from a larva at a pre-pupal stage, about six days older. The lines indicate the corresponding loci of the chromosomes at these two larval stages]

The autoradiographic method using tritiated thymidine confirms the statement made by Breuer and Pavan[7] in Rhynchosciara and Beerman[6] and Mechelke[9] in Chironomidae, namely, that genes have different activities at different stages of larval development.

Kojibiose (2-O-α-D-Glucopyranosyl-D-Glucose): Isolation and Structure

Isolation from Hydrol

IT has previously been reported that saké and koji extract produced from rice by the application of *Aspergillus oryzae* contains two new disaccharides[1], one of which has been confirmed to be 1 : 3-α-linked gluco-biose (kojibiose)[3,4] by its conversion into glucose with acid, R_F in paper chromatography, M_G in ionophoresis in borate buffer, its resistance to almond β-glucosidase, lack of formation of osazone and the similarity of its stain (aniline hydrogen phthalate spray) to that of sophorose. Peat *et al.*[4] have also described the isolation of a gluco-biose (octaacetate; melting point 166°, $[\alpha]_D + 153°$), believed to contain the 1 : 2-α-linkage, from a mixture of disaccharides synthesized from glucose by *Aspergillus niger*. One of us (K. A.) has detected kojibiose in the acid hydrolysate (hydrol) of sweet potato starch which is known to have undergone marked reversion[5]. We now report the isolation of this sugar from hydrol.

The preliminary fractionation of hydrol was carried out by the usual method of carbon column chromatography and the effluent portion of the 3–5 per cent ethanol fraction was collected. Then the techniques of carbon column chromatography of the free sugars in the presence of borate buffer (pH 10·0)[6], followed by 'Magnesol-Celite' column chromatography of the acetates, were used for the further fractionation. In addition to the octaacetate of isomaltose, maltose and β,β-trehalose, two reducing disaccharides were isolated as their crystalline octaacetates, the properties of which distinguished them from the other disaccharide octaacetates. One of them, herein designated α-kojibiose octaacetate, showed melting point 166° (uncor.) and $[\alpha]_D + 150°$ (*c.* 2·1 in chloroform) (calc. for $C_{28}H_{38}O_{19}$: C, 49·55; H, 5·64 per cent; found: C, 49·79; H, 5·85 per cent), being in good agreement with those reported by Peat *et al.*; and the other, designated β-kojibiose octaacetate, melting point 118° (uncor.) and $[\alpha]_D + 112°$ (*c.* 2·0 in chloroform) (calc. for $C_{28}H_{38}O_{19}$: C, 49·55; H, 5·64 per cent; found: C, 49·40; H, 5·50 per cent). Neither acetate showed depression of melting point on admixture with samples synthesized chemically by Matsuda (see following communication).

Free sugars obtained by deacetylation from α- and β-acetate gave $[\alpha]_D + 136°$ (equil.: *c*, 0·5 in water) and + 140° (equil.: *c*, 0·6 in water), respectively; these high values, being in fairly good agreement with those of the 1 : 2-α-linked gluco-biose reported very recently by Barker *et al.*[7] and by Whelan *et al.*[8], suggested the presence of an α-linkage. Both sugars also had the following properties: (*a*) acidic hydrolysis gave glucose as the only product detectable by paper chromatography; (*b*) their resistance to almond β-glucosidase; (*c*) ionophoresis in borate buffer (pH 9·8) showed M_G 0·31, which eliminated the

1 : 3- and 1 : 6-linkages; (*d*) the R_F 0·22 on paper chromatography (pyridine/butanol/water : 4 : 6 : 3) eliminated the possibility of maltose; (*e*) neither was developed by alkaline triphenyltetrazolium chloride[9], which detects all reducing glucosaccharides except those with a 2-O-substituent; (*f*) further indication of C-2-substitution was their low reducing power (about 6 per cent of glucose) towards the Shaffer–Hartmann reagent[10]; (*g*) their stains on filter paper (aniline hydrogen phthalate spray) were similar to that of sophorose.

All these properties are consistent with the structure of 2-O-α-D-glucopyranosyl-D-glucose. Thus the above two sugars are both 2-O-α-glucopyranosyl-D-glucose (kojibiose).

It is hoped to publish full details elsewhere.

Chemical Synthesis

I HAVE previously pointed out that kojibiose (one of the unfermentable gluco-bioses in koji extract) is believed to have most probably 1,2-α-glucosidic linkage from the following facts: (*a*) acid hydrolysis gave glucose as the only product detectable by paper chromatography[1]; (*b*) resistance to almond β-glucosidase eliminates the β-linkage[1]; (*c*) the low M_G value[2] (0·31) in borate buffer (*p*H 9·8) suggests that the linkage cannot be 1, 3- or 1, 6-, and the R_F value in butanol/pyridine/water (3 : 2 : 1·5) is different from that of maltose as well as from sakébiose (nigerose) and *iso*maltose[3]; (*d*) the stain of this sugar on the paper chromatogram sprayed by aniline hydrogen phthalate has a colour similar to that of sophorose[3]; (*e*) this sugar gives no phenylosazone by the usual method, though it showed reducing power against Fehling's solution[4].

For the direct proof of the structure of this new sugar, chemical synthesis of 1,2-α-linked gluco-biose was carried out. The method of synthesis was suggested by the observation of Zemplen[5] that the use of mercuric salt in the Königs–Knorr reaction tends to give α-linkage. This view was further supported by the fact that α,β-trehalose octaacetate was prepared by using mercuric cyanide[6].

α-Kojibiose octaacetate was prepared in the following manner. 3,4,6-Tri-O-acetyl-β-D-glucopyranosyl chloride (I) was prepared according to the procedure described by Brigl[7]. This was treated with mercuric acetate in acetic acid at room temperature for two hours. 1,3,4,6-Tetra-O-acetyl-α-D-glucopyranose (II) was obtained; melting point 98–100°, $[\alpha]^{15}_{D} = +143°$ (*c*, 3·0; chloroform) (calc. for $C_{14}H_{20}O_{10}$; C, 48·27; H, 5·78 per cent; found: C, 47·90; H, 5·58 per cent).

Gakhokidze[8] has obtained the β-isomer of the above tetra-O-acetyl-D-glucose (melting point 138°) by the treatment of (I) with silver acetate. But the high $[\alpha]_D$ value shows that the tetraacetate obtained by us is the hitherto unknown α-isomer.

Equimolecular portions of (II) and 2,3,4,6,-tetra-O-acetyl-α-D-glucopyranosyl bromide (III) were shaken in anhydrous nitromethane with mercuric cyanide for 8 hr. at room temperature. The reaction mixture was filtered and evaporated to a syrup. The residual (III) was removed by precipitation with a slight excess of benzylamine in absolute ether. The ether solution was washed first with dilute hydrochloric acid, then repeatedly with water and evaporated to a syrup. This syrup crystallized very slowly when dissolved in absolute ethanol and kept at 20° for two weeks. The twice-recrystallized product showed melting point 166°, $[\alpha]^{15}_{D} = +152·8$ (*c*, 2·0; chloroform) (calc. for $C_{28}H_{38}O_{19}$: C, 49·55; H, 5·64 per cent; found: C, 49·75; H, 5·83 per cent).

These values are in good agreement with those reported by Peat *et al.*[9] and also with those obtained from hydrol as above. The melting point was not depressed on admixture with the specimen obtained from hydrol. The β-octaacetate was obtained by acetylating the free sugar with acetic anhydride and anhydrous sodium acetate; melting point 118°, $[\alpha]^{15}_{D} = +113°$ (*c*, 2·0; chloroform) (calc. for $C_{28}H_{38}O_{19}$: C, 49·55; H, 5·64 per cent; found: C, 49·42; H, 5·26 per cent). This was found to be identical with the specimen obtained from hydrol and also with that obtained from koji extract.

I wish to acknowledge my indebtedness to Prof. K. Aso for his guidance and encouragement.

Effects of Kinetin on Division of Yoshida Sarcoma Cells

KINETIN (6-furfurylaminopurine) was isolated by C. O. Miller *et al.*[1] from deoxyribonucleic acid from herring sperms. They found that it induced a high rate of cell multiplication in the callus tissue of plants. R. Guttman's work[2] has shown that, in onion root-tip cells, kinetin promoted mitotic division, and induced polyploidy and various forms of pycnosis in addition. However, its effect on the division of animal cells is not well known, though negative results have been reported by H. Lettré[3] using animal and human cells.

We have investigated the effect of kinetin (kindly supplied by Dr. F. G. Okumura) on the mitotic activity of Yoshida sarcoma cells transplanted to

Table 1. FREQUENCY OF MITOTIC FIGURES AFFECTED BY THE INJECTION OF KINETIN

Time after inject. (hr.)	Control	Kinetin		
		0·03 mgm.	0·15 mgm.	0·75 mgm.
48 48 48	6·25 per cent 4·77 4·33	5·31 per cent 3·51	3·09 per cent 2·75	3·65 per cent 3·51
120 120 120	2·56 2·88 2·60	2·39 2·47	4·12 3·88	2·73 2·41

Host: Wistar rat, 2 months old. Preparation: aceto-orcein staining by squash technique. The percentage of dividing cells was determined by the observation of 10,000 cells. No dividing cell was found in the ascites if kinetin only was injected and the sarcoma had not been transplanted. Between 2 and 7 days after transplantation of Yoshida sarcoma, the error variation in the frequency of mitotic figures is very low, and we have therefore used this period

Table 2. ANALYSIS OF THE FREQUENCY OF DIVIDING CELLS

Source	Degree of freedom	48 hr Mean sq.	120 hr. Mean sq.
Treatment	3	4·66	3·99*
Error	5	1·82	0·1

* Significant at 1 per cent level.
Standard error: control, 0·183; after treatment, 0·224.

Wistar strain rats. Injecting the solution of kinetin into the abdomen, a significant increase in the frequency of mitotic figures was found in the tumour cells after about 120 hr. (significant at the 1 per cent level, as shown in Tables 1 and 2). However, no significant effect was found on the relative frequency of the mitotic stage. This suggests that kinetin may promote the mitotic division of tumour cells, but does not affect a specific stage of mitosis.

In the non-treated control, as shown in Fig. 1, the frequency curve for metaphasic cells showed two periods of increase, two and ten days after the transplantation of Yoshida sarcoma. In the treated rats, the second period of increase was not apparent, possibly because the animals were nutritionally exhausted during the first period of increase, which had continued longer than in the non-treated animals. The observed frequency curves for treated rats do not show any indication of an abrupt change, and seem to suggest that the effect of kinetin may be direct and not due to a secondary metabolite. Thus we have found a case in which kinetin can induce a high rate of multiplication in animal cells as well as in plant cells.

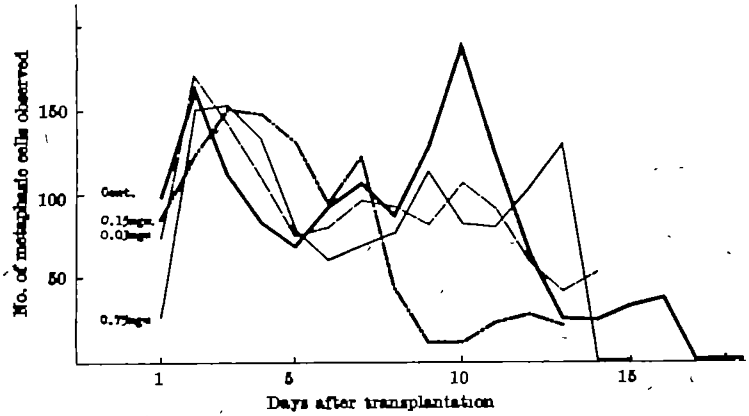

Fig. 1. Daily change of frequency of metaphasic cells (pathological figures excluded) after injecting kinetin into the abdomen of rats, 10,000 cells being observed per day

We thank Dr. Motoo Kimura for help in the statistical treatment of our results.

An Immuno-electrophoretic Technique

INTEREST in immuno-electrophoresis and its application both to research and in clinical pathology is rapidly increasing. I have developed a technique which is comparatively simple, reliable and very economical in the use of the anti-serum, which is still quite difficult to obtain. An additional advantage is the very distinct separation of the alpha-1 fraction, which usually is only poorly separated in agar electrophoresis. The electrophoretic pattern can be controlled according to requirements by adjusting the current time, buffer concentration and pH and the fluid levels in the buffer compartments.

The technique is based on the principle of the Grabar–Williams method[1], and is a combination of cellulose acetate membrane filter electrophoresis[2] and the agar diffusion method. It consists in applying the membrane filter strip with the separated fractions (electrophoretic strip) and a filter paper impregnated with anti-serum (anti-serum strip) to the surface of the agar and letting the various fractions and the anti-serum diffuse into the agar and form precipitates where antigen and antibody meet at optimal concentration.

The electrophoresis is performed on membrane filter strips (obtainable from Messrs. Oxo, Ltd. (Med. Dept.), 16 Southwark Bridge Road, London). Buffered 1·0 per cent agar slabs, 18 cm. × 7·5 cm. and about 2–4 mm. thick, mounted on glass plates of suitable dimensions, were prepared as described by Grabar and Williams[1]; 1·0 per cent non-dialysed clear isotonic saline agar buffered to pH 8·2 also gave satisfactory results. Equine anti-human serum was obtained from the Pasteur Institute. A plan indicating the exact positions of the electrophoretic strips and the anti-serum strip is drawn on white paper and placed underneath the agar slabs (Fig. 1). A sample of the material to be investigated is applied to the membrane filter strip and an electrophoretic run performed. On completion, the strip is removed from the tank and cut lengthwise into halves, and a 1-cm. length at each end is cut off. One half of the strip is placed immediately on the surface of the agar as indicated on the plan, cut side facing the anti-serum strip. This step must be carried out quickly, for the strip must not dry out. Either following (or preceding) it the filter paper strip is soaked with an adequate amount of the anti-serum, usually 0·2–0·3 ml., and placed immediately in its position on the agar slab

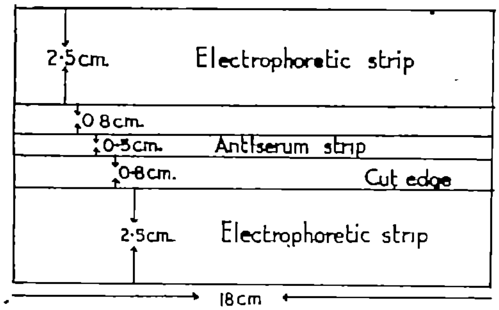

Fig. 1

at a distance of approximately 0·8–1 cm. from the electrophoretic strip. The quantity of anti-serum and the optimal distance vary according to the concentrations of the material investigated and the titre and type of the anti-serum. The more potent the anti-serum the greater can be the distance. A second electrophoretic strip may be placed on the other side of the anti-serum strip so that two samples can be investigated at the same time, thus halving the quantity of anti-serum to be used. The second half of the electrophoretic strip is dried and stained to show the electrophoretic pattern and serves as an accurate and reliable guide to the positions of the various fractions in relation to the precipitation lines.

Alternatively, only the centre part of the electrophoretic strip is cut out, discarding both margins, and is then placed on the middle of the agar slab with an anti-serum strip applied on each side. In this case, of course, no stained replica is available. The agar slab with the applied strips is then placed in a moist chamber at room temperature, avoiding large temperature fluctuations, and left there for the diffusion and precipitation process to proceed.

The first precipitation lines are usually visible after 24 hr. Within three to four days most of the lines are already developed. This depends, of course, on the titre of the anti-serum and the distance between the anti-serum strip and the electrophoretic strip. The precipitation lines in the form of arches are best seen against a black background with oblique illumination and may be photographed at this stage without staining. When the diffusion process is considered to be completed, both the electrophoretic and the anti-serum strips are removed and a sheet of filter paper of suitable size to cover the whole slab is then placed on the agar surface, and the agar, still on the glass plate, is transferred to a 37° C. incubator for drying. Drying is usually completed overnight and the agar is reduced to a thin sheet suitable for staining. The covering filter paper is then detached and the agar slab, now firmly stuck to the glass plate, is placed in a 2 per cent acetic acid solution for three to four hours for fixation. This step, however, does not appear to be essential as the precipitated proteins are insoluble, and also because the staining solutions contain acetic acid which acts as a fixative. For serum proteins azocarmin *B* (0·05 per cent in 2 per cent acetic acid) and Masson's Ponceau fuchsin stain (diluted 1 : 4 with 2 per cent acetic acid in 20 per cent alcohol) were used with very satisfactory results. The dried agar slab remains in the staining solution for four to six hours until the precipitation lines are well stained and distinct. Following the staining, the preparation is transferred into a solution of 10 per cent glycerine in 2 per cent acetic acid for about 30 min. for differentiation and to render the agar pliable. It is then dried in the incubator at 37° C. or at room temperature and can be detached from the glass plate if so desired. The details of drying, fixing and staining are those of the Uriel and Grabar technique[3] with only minor changes.

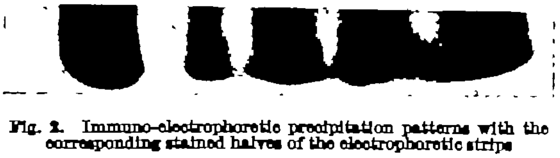

Fig. 2. Immuno-electrophoretic precipitation patterns with the corresponding stained halves of the electrophoretic strips

A typical example of the results obtained is shown in Fig. 2. It should also be pointed out that the background is usually clear and shows only traces of residual proteins. This is due to the comparatively small quantities of proteins applied; consequently, very little excess protein is left after precipitation. The saline washing for the removal of excess residual proteins can, therefore, be omitted. An additional advantage is that for studies of isolated fractions it is much easier to cut the electrophoretic strip into segments than when an agar supporting medium is used.

Note added in proof. Since this communication was submitted I have developed a 'micro' technique which is much more rapid and economical. Only about 0·05 ml. of anti-serum is used for one experiment, and the time is cut down to 24–48 hr., including the electrophoretic run. Full details will be reported later.

Use of Pilocarpine in Pancreatic Research

The ability of pilocarpine to deplete the pancreas exocrine cells of zymogen granules has been utilized by cytologists[1] and biochemists[2] in their studies of secretion processes in this very active organ. Generally, changes observed microscopically or results derived chemically have been accepted as attributable to the direct effect of the drug on the pancreas. The purpose of this report is to direct attention to several other effects of pilocarpine which should be of interest to those following this line of investigation. These probably do not diminish the value of the drug as an experimental tool, but they do indicate that its effects are not confined to the pancreas. This fact should be taken into account in the interpretation of results.

In brief, these additional effects of pilocarpine in the dosages usually employed in pancreatic research are: apparent stimulation of the adrenal medulla, diminution of glycogen in the liver, and hyperglycaemia.

Table 1 shows the effect of pilocarpine administered subcutaneously on the level of blood sugar in male rats weighing 200–225 gm. One rat was used for each determination[3]. These studies indicate that the effects of pilocarpine occur soon after injection. The blood sugar reaches hyperglycaemic levels within 15 min. but falls to about normal in 1 hr. A similar response has been found in mice.

As assessed by periodic acid–Schiff glycogen stains[4], the amount of glycogen in the liver is significantly reduced within ½ hr. after the administration of 2 mgm. of pilocarpine given subcutaneously to a rat weighing 200 gm.; within 1 hr. the depletion is considerable and may be complete. Mice, with an average weight of 22–25 gm., given 0·5 mgm. of pilocarpine subcutaneously, showed slightly diminished glycogen in 1 hr. and 3 hr.; those given 1 mgm. displayed essentially complete loss in 1 hr. and 3 hr.; while in mice given 2 mgm. there was apparent absence of liver glycogen in 1 hr. and 3 hr. Although the diminution in glycogen in the liver is sustained for several hours, mice given 1 mgm. of pilocarpine regain much liver glycogen within 7½ hr., and at 8½ hr. approximately normal amounts of glycogen are present.

Table 1. Effect of Pilocarpine on Blood Sugar of the Rat

Time after injection	Level of blood sugar (mgm./100 ml.)		
Dose of pilocarpine	1 mgm.	2 mgm.	4 mgm.
15 min.	178	153	179
30 min.	182	182	201
45 min.	118	194	231
60 min.	116	138	118

Hrubetz[5], also studying rats, similarly found that pilocarpine in the dosage of 5 mgm./kgm. raises the level of blood sugar with a maximum effect produced in 15 min. In her studies of related drugs she found that atropine lowers the level of blood sugar with a maximum effect in 90 min. and prevents the rise in blood sugar after pilocarpine. Acetylcholine lowers the level of blood sugar, the lowest point being reached in 20 min. Physostigmine also raises the level of blood sugar, and has a maximum effect in 1 hr. with a return to the original level in 2 hr. Atropine prevents hyperglycaemia after physostigmine.

It would appear that pilocarpine and physostigmine stimulate the adrenal medulla, leading to increased output of epinephrine; this would account for the above results.

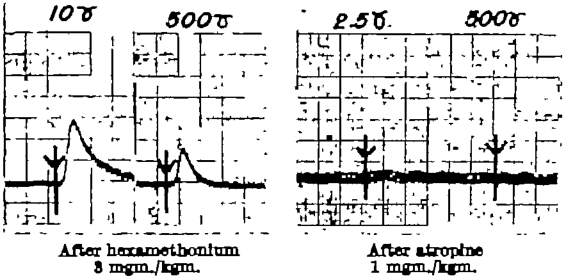
Muscarinic Action of Murexine and Some Related Choline Esters

SEVERAL reports have indicated that murexine (β-imidazolyl-4-(5)acrylcholine) has strong nicotinic and curare-like actions but shows little or no muscarinic action[1–4]. Recent work in our laboratories[5] suggests that murexine and two related esters, imidazolepropionylcholine and imidazoleacetylcholine, have significant cholinomimetic (muscarinic) activity on the vascular system of the intact dog. When injected intra-arterially in anaesthetized dogs, murexine and the two esters produced a local vasodilatation which was blocked by atropine but not by hexamethonium.

A series of five dogs was anaesthetized with sodium pentothal followed by α-chloralose. The femoral arterial flow-rate was measured with a rotameter placed in series between the central and peripheral ends of the artery. Blood pressure was recorded simultaneously with a pressure transducer.

Intra-arterial injection (into the tubing from the rotameter to the artery) of 100–500 μgm. of murexine or imidazolepropionylcholine or 1–2 mgm. of imidazoleacetylcholine produced a sharp rise in the blood flow-rate (vasodilatation) which lasted from 15 to 90 sec. There were no changes in the systemic arterial pressure. A similar response was observed following 1–10 μgm. of acetylcholine. This local vasodilator action of murexine, acetylcholine and the other choline esters was blocked completely by atropine, 1 mgm./kgm. intravenously, but was not blocked by hexamethonium, 2–3 mgm./kgm. intravenously (Fig. 1). The action of atropine was specific since the vasodilator action of intra-arterial histamine (1–10 μgm.) was not blocked.

Intravenous injection of imidazolepropionylcholine (0·5–2 mgm./kgm.) or imidazoleacetylcholine (1–4 mgm./kgm.) produced a marked hypertension frequently preceded by bradycardia and slight transient hypotension. A similar hypertensive response was observed after 10–15 μgm./kgm. of 1,1-dimethyl-4-phenylpiperazinium. After hexamethonium (2–3



After hexamethonium
3 mgm./kgm.

After atropine
1 mgm./kgm.

Fig. 1. Effect of hexamethonium or atropine on the vasodilator action of murexine (*m*) and acetylcholine (*ACh*). The injection is indicated by the arrow on the blood-flow record. Each heavy time line represents 20 sec.

mgm./kgm. intravenously) 1,1-dimethyl-4-phenylpiperazinium produced no change in blood pressure or heart-rate, whereas imidazolepropionylcholine and imidazoleacetylcholine lowered the blood pressure and heart-rate. Atropine (1 mgm./kgm. intravenously), before or after the hexamethonium, eliminated the depressor and bradycardic phase.

Thus, it has been concluded that murexine and the two related esters have two types of autonomic cholinergic properties on the circulatory system—nicotinic and muscarinic. This is based on the following facts: (1) the rise in blood pressure on intravenous injection of the choline esters was blocked by hexamethonium (nicotinic); (2) the local vasodilatation on intra-arterial injection was blocked by atropine and not by hexamethonium (muscarinic); (3) after blockade of the intravenous pressor effect by hexamethonium there was a depressor and bradycardic component which could be blocked by atropine (muscarinic).

Carbon Dioxide as a Reversible Inhibitor of Spermatozoan Metabolism

LOW-TEMPERATURE storage (+ 5° to − 79° C.) has been the primary means of preserving the life and fertility of mammalian spermatozoa *in vitro*. Experiments in our laboratory have repeatedly shown that low levels of carbon dioxide prolonged the life of bovine sperm at 37° C. under either aerobic or anaerobic conditions[1]. Recent experiments have shown that high concentrations of carbon dioxide in a properly buffered medium reversibly inhibit sperm motility and metabolism. Preliminary results have shown that the fertility of bovine semen stored for several days at room temperature in a diluent saturated with carbon dioxide is not impaired[2].

The inhibitory effect of various levels of carbon dioxide on glycolysis by bovine spermatozoa suspended in a new diluent, and the reversibility of this inhibition, are reported here. The new diluent, called the 'Illini variable-temperature diluent', was composed of 20·0 gm. sodium citrate dihydrate, 2·1 gm. sodium bicarbonate, 0·4 gm. potassium chloride, 3·0 gm. glucose, and 3·0 gm. sulphanilamide, dissolved (by heating to near boiling) in a litre of glass-distilled water. One million I.U. of penicillin G and 1·0 gm. dihydrostreptomycin sulphate were added before use.

In the first studies, 0·2 ml. semen was added in Warburg flasks to 0·8 ml. of our diluent from which the antibacterial agents were omitted. The contents were gassed for ten minutes with nitrogen, carbon dioxide, or nitrogen containing from 5 to 75 per cent carbon dioxide. The contents of the flasks gassed with 100 per cent carbon dioxide reached an initial *p*H level of 6·3. The glycolytic rates as measured by evolution of carbon dioxide at 37° C. were used for periods ranging from 4 to 24 hr. to determine the inhibitory effects of the gas phase.

Table 1. GLYCOLYTIC ACTIVITY OF BOVINE SPERMATOZOA IN VARIOUS GASES DURING INCUBATION FOR 4 HR. AT 37° C. IN ILLINI VARIABLE-TEMPERATURE DILUENT CONTAINING NO ANTIBACTERIAL AGENTS

Time (hr.)	Carbon dioxide evolved (μl.)/10^{8} spermatozoa				
	Nitrogen	5% carbon dioxide	25% carbon dioxide	50% carbon dioxide	100% carbon dioxide
1	38·7	40·6	19·4	9·6	6·0
2	66·4	64·3	25·4	12·2	7·5
3	82·9	79·9	31·7	13·7	5·9
4	93·9	87·7	36·4	14·6	5·7

As shown in Table 1, with Illini variable-temperature diluent the glycolytic rate on a mean of three semen samples during the initial 4-hr. period tended to be optimum at the 5 per cent carbon dioxide level for the first hour, but afterwards was depressed slightly below that in 100 per cent nitrogen. Each higher amount of carbon dioxide in the gas phase resulted in an increased inhibition of glycolysis. With some semen samples the inhibition of glycolysis was maximum with the 50 per cent carbon dioxide gas mixture. With others, higher levels of carbon dioxide were required, and the inhibition of the initial glycolysis was essentially completed by the end of the first hour under 100 per cent carbon dioxide.

At the end of selected 4-hr. periods, inhibition was reversed by flushing the flasks and contents with a mixture of 95 per cent nitrogen and 5 per cent carbon dioxide. As shown in Table 2, the rate of glycolysis by the previously inhibited sperm returned to the level initially exhibited by the sperm under the low carbon dioxide mixture.

Table 2. GLYCOLYTIC ACTIVITY OF BOVINE SPERMATOZOA IN A MIXTURE OF 5 PER CENT CARBON DIOXIDE AND 95 PER CENT NITROGEN BEFORE AND AFTER 24 HR. UNDER 100 PER CENT CARBON DIOXIDE AT 37° C. IN ILLINI VARIABLE-TEMPERATURE DILUENT CONTAINING THE ANTIBACTERIAL AGENTS

Time (hr.)	Carbon dioxide evolved (μl.)/10^{8} spermatozoa	
	Initial	Final
1	41·5	24·0
2	57·0	41·9
3	65·5	57·4
4	72·4	70·0

Table 2 illustrates a lag in the recovery. Spermatozoan motility estimations were made on the flask contents after completion of the 4-hr. period following reversal of the inhibition. In the case of the results in Table 2, 50 per cent of the total cells still showed vigorous motility. The final *p*H of the flask contents was 6·76.

The rate of glycolytic activity following inhibition was directly related to the completeness of the initial inhibition. When inhibition was maximal during the 24-hr. period, both motility and glycolytic rates in the subsequent 4-hr. period were essentially the same as those in the initial 4-hr. period under 5 per cent carbon dioxide. Incomplete inhibition often resulted in death of the sperm cells during the 24-hr. period at 37° C. Following reversal of the maximal inhibition, oxygen consumption was at levels similar to that during an initial 4-hr. period. On the other hand, when inhibition was incomplete and death ensued, respiration could occur at reduced levels. The practical application of these observations in the preservation of semen for artificial insemination are readily apparent.

These experiments were supported in part by grants from the Rockefeller Foundation and the Illinois Dairy Cattle Breeding Federation.

Phenols as Inhibitors of the Heparin Co-factor of Plasma

Phenols counteract the antithrombic activity of plasma and serum[1]. The antithrombic activity is present in a protein fraction which also contains the co-factor required for the anticoagulant effect of heparin[2]. The antithrombic and the heparin co-factor activity are present in the α-globulin fraction of human plasma[3]. It was therefore of interest to test the influence of phenols on heparin activity in plasma.

The results indicate that the phenols tested partly counteracted the heparin effect in human oxalated plasma. On a molar basis *p*-cresol is more active than the other compounds; a similar behaviour was noted with phenols in the counteraction of antithrombic activity.

Phenols accelerate the thrombic fibrinogen reaction[4] by a factor of approximately 2. The observed shortening of the thrombin clotting time by phenols in the presence of heparin is far greater, therefore it cannot be due solely to this effect. The phenomenon could be due either to destruction of heparin or to a partial inactivation of the heparin co-factor. Heparin is not destroyed by phenol since phenol can be used for the quantitative isolation of heparin from plasma[5]. Further evidence that pyrocatechol does not inactivate heparin itself was obtained from experiments in which twice as much heparin was added to oxalated human plasma under conditions similar to those given in Table 1, both in the presence and absence of 0·36 *M* pyrocatechol. The recovery of heparin was approximately 80 per cent in both cases.

It is therefore most likely that the phenols have the property of inhibiting the co-factor of heparin activity. The physiologically occurring phenols—adrenaline, noradrenaline, tyrosine, natural œstrogens and synthetic œstrogens—in saturated solutions in the buffer system used had no effect on heparin activity.

Table 1. Influence of Phenols on Heparin Activity
Reaction mixture consisted of 0·2 ml. plasma, 0·05 ml. veronal buffer, *p*H 7·1, containing the phenols and 0·05 ml. veronal buffer, *p*H 7·1, containing heparin. Incubation for 1 min. at 37° C. Addition of 0·1 ml. human thrombin dissolved in veronal buffer, *p*H 7·1

Heparin antagonists have been described to occur in crude preparations of adrenocorticotrophic hormone[6]. However, the mechanism was not established. It should be pointed out that for the preparation of corticotrophin solution, phenol is used often and this, of course, would affect heparin activity in plasma.

There are two classes of heparin antagonists: basic substances which bind heparin, and thus annul the heparin effect, and the phenols which counteract the heparin co-factor.

A Hitherto Unknown Blood Clotting Defect in Hæmophilia and Christmas Disease

Many consider that the blood clotting defect in hæmophilia and Christmas disease is due to a deficiency of one of the blood clotting factors, namely, antihæmophilic globulin[1] or Christmas factor (plasma thromboplastin component)[2]. Others believe that the anomaly is produced by a derangement in the balance between a lipid inhibitor and a platelet plasma co-factor[3].

While investigating the specificity of different forms of plasma thromboplastin[4], we noticed that incomplete plasma thromboplastin—that is, thromboplastin formed in the absence of antihæmophilic globulin or Christmas factor—clotted normal substrate (plasma) in a shorter time than hæmophilic or Christmas disease (Table 1). This difference in the times of clotting was not materially affected on the addition of antihæmophilic globulin or normal serum (Christmas factor) to the substrates, respectively. This indicated that it was due to a

Table 1. Effect of Incomplete Plasma Thromboplastin on Normal and Patients' Substrates

Reagents incubated with 0·025 *M* calcium chloride (equal volumes)	Clotting time of substrate (sec.)*	
	Normal plasma	Patients' plasma
Hæmophilic plasma adsorbed by aluminium hydroxide (1 : 5) Normal serum (1 : 10) Platelet suspension	40	59
Normal plasma adsorbed by aluminium hydroxide (1 : 5) Christmas disease serum (1 : 10) Platelet suspension	32	47

* The activity of the incomplete plasma thromboplastin formed in the incubation mixture was tested after 6 min., by taking 0·1 ml. thereof together with 0·1 ml. 0·025 *M* calcium chloride, adding them simultaneously to 0·1 ml. substrate at 37° C., and recording the clotting time.

cause other than the deficiency of these factors in the substrates. Since the concentration of prothrombin in the plasmata of these diseases is known to be normal[5], further experiments were carried out in order to elucidate the cause of their delayed clotting. The results[6] have shown the presence of an anticoagulant which counteracts the action of incomplete plasma thromboplastin on prothrombin. In addition, this anticoagulant was found to inhibit the interaction between Christmas factor, antihæmophilic globulin and platelets.

The anticoagulant is a congenital anomaly, being present in the plasma of 123 patients who were examined, six of whom had received no blood transfusions. A study of its properties showed that it bears no resemblance to any inhibitor of blood clotting previously described. It is not adsorbed on glass, aluminium hydroxide, kaolin or asbestos, and is absent in serum.

It is now our opinion that the defect in these two diseases is produced by a deficiency in a blood clotting factor as well as by the presence of this inhibitor termed Bridge anticoagulant. The concentration of the latter seems to influence greatly the clinical picture (unpublished work).

Nucleic Acid Metabolism in Megaloblastic Marrows *in vitro*

Davidson *et al.*[1] reported that the deoxyribonucleic acid phosphorus content is increased above normal in megaloblastic bone marrow. Vilter *et al.*[2], on the other hand, on the basis mainly of deoxyribonucleic/ribonucleic acid ratios, claimed that megaloblasts are deficient in deoxyribonucleic acid, more specifically in thymine.

Formate carbon-14 in bone marrow cultures *in vitro* labels nearly exclusively deoxyribonucleic acid; about 95 per cent of the radioactivity is found in the 5-methyl group of deoxyribonucleic acid thymine[3]. Earlier work from this laboratory reported that megaloblasts ripen in normal serum, their ripening is inhibited by pernicious anæmia serum, and pernicious anæmia serum may cause the transformation of normoblasts into megaloblasts[4]. Both folic acid and citrovorum factor cause maturation of megaloblasts *in vitro*.

In view of the above observations, it was decided to investigate the uptake of formate carbon-14 (sodium formate carbon-14, specific activity 4·85 mc./m.mole, 1·25 μc./ml. medium) in cultures of megaloblastic marrows in normal and in pernicious anæmia sera. The methods for culturing bone marrow cell suspensions *in vitro* and for a high-resolution autoradiography on smears prepared from such cultures have been published previously[4]. Grain counts over individual cells indicated the amount of formate carbon-14 incorporated into deoxyribonucleic acid (Fig. 1).

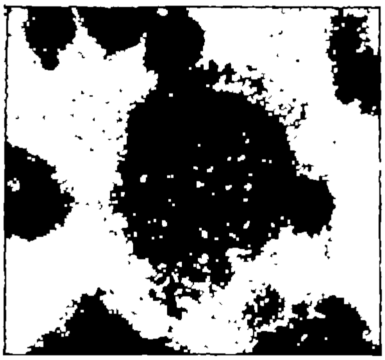

Fig. 1. Localization of formate carbon-14 in megaloblast cultured *in vitro*. Stained autoradiograph. (× 2,000)

Tables 1 and 2 indicate that the incorporation of formate carbon-14 into deoxyribonucleic acid was not significantly influenced by the type of serum in the culture medium. Pernicious anæmia sera certainly did not cause an inhibition of uptake. On the contrary, there is a suggestion of a slightly increased uptake in such sera. Citrovorum factor also did not significantly influence the uptake of formate carbon-14 into megaloblasts. No difference was found in uptake between normoblasts and megaloblasts.

In 24-hr. cultures of six normal marrows in normal serum and eight pernicious anæmia marrows in pernicious anæmia serum a comparison was made of the formate carbon-14 and adenine carbon-14 uptake *in vitro*. Table 3 indicates that the deoxyribonucleic acid labelling of the myelocytes is similar, whether they originate from normal or pernicious anæmia marrows, but the megaloblasts show higher grain counts than the corresponding normoblasts (basophilic grade). The ribonucleic acid labelling, however, is about twice as high in myelocytes and nearly 3·5 times as high in megaloblasts from pernicious

Table 3. Deoxyribonucleic Acid and Ribonucleic Acid Synthesis in Normoblastic and Megaloblastic Marrows
Grain counts in 24-hr. cultures

Label	Normal marrows		Pernicious anæmia marrows	
	Normoblasts	Myelocytes	Megaloblasts	Myelocytes
Formate carbon-14 (DNA)	120	98	170	100
Adenine carbon-14 (DNA + RNA)	245	185	603	295
Adenine minus formate = RNA	125	87	433	195
DNA/RNA	0·96	1·10	0·39	0·51

anæmia marrows than in myelocytes or normoblasts from normal marrows (inter-marrow variations of grain counts over myelocytes or erythroblasts is ± 10 per cent).

These observations complement earlier findings by Davidson *et al.*[1] and indicate that in pernicious anæmia marrows deoxyribonucleic acid synthesis is slightly increased in megaloblasts but not in the myelocytes. Synthesis of ribonucleic acid, however, is greatly increased in myelocytes and even more so in megaloblasts of pernicious anæmia marrows. Since in short-term (6–20 hr.) cultures no marked difference was noted between normal and pernicious anæmia serum in the medium, it is suggested that the megaloblastic change takes more than 20 hr. to develop. This is in agreement with earlier observations on the formation of megaloblasts in normal marrows cultured in pernicious anæmia serum[4].

The underlying biochemical defect in the megaloblasts is far from clear. Determinations based on deoxyribonucleic/ribonucleic acid ratios may be misleading, because a greatly increased ribonucleic acid and a slightly less increased deoxyribonucleic acid content may give the erroneous impression of deficiency in deoxyribonucleic acid.

Effect of Ultra-violet Light on Mouse Skin over a Wide Range of Intensities

Whether the effect on the living skin of a constant dose of ultra-violet radiation is the same if given with high intensity in a short pulse as if given with low intensity over a longer period of time has not apparently been recorded. We have therefore examined the tissue injury caused in mouse skin by ultra-violet light of wave-length about 300 mμ when the intensity of the incident light was varied from 10^{14} to 10^{21} $h\nu$/cm.^{2} sec.

A high-pressure mercury lamp with appropriate filters (2 mm. Jena *WG* 7 + 10 mm. $NiSO_4.6H_2O$, 500 gm./l.) served as source of light at the lower intensities. To obtain different intensities, working distances of about 10, 12, 35, 40 and 140 cm. were used with exposure times varying from ½ min. up to 120 min. The light pulse of high intensity was obtained from a photolysis flash lamp with maximum emission at about 300 mμ [1] provided with the same filters. The working distance was 4·5 cm., giving a constant average light-intensity of about 1·3 × 10^{21} $h\nu$/cm.^{2} sec. or about 860 watts/cm.^{2}; suitable exposure times were 50–150 μsec. The intensities and doses were determined by means of chemical actinometry (both uranyloxalate and potassium ferrioxalate).

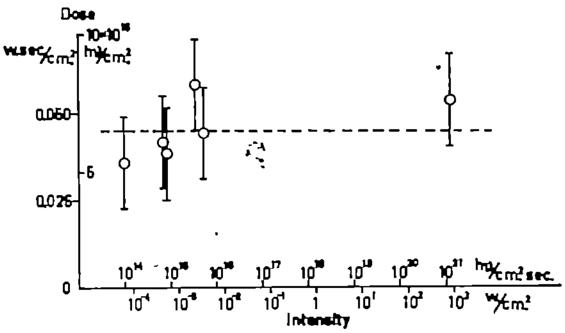

Fig. 1. The relation between light intensity (λ ∼ 300 mμ) and minimum dose to cause tissue injury in mouse skin

The mice, a commercial albino stock, were shaved with a barium sulphide paste on the back. They were fastened rigidly without anæsthesia by means of black rubber sheets to plane wooden boards and irradiated on the back through 20 mm. circular openings in the sheets. Each animal was normally irradiated at two positions, both placed over the spine, with about 25 mm. between their centres. A total of about 100 animals were used in the experiments reported here.

The degree of tissue damage was estimated by the leakage into the irradiated areas of intravenously injected Evans blue. A volume of 0·3 ml. of the dye solution (0·5 per cent in saline) was injected intravenously 20 hr. after irradiation. The animals were killed 15 min. after injection. The degree of blueing, estimated by visual colorimetry of the dried skin, was plotted as a function of the irradiation dose. From these curves the minimum dose causing blueing was estimated and is plotted against intensity in Fig. 1. It is evident that this minimum dose is virtually constant over a 10^7-fold change in intensity.

The intensity of the blueing increases with the dose of radiation up to a certain point. The blueing then gradually becomes weaker, probably due to a decrease in blood supply as the damage is increased. This latter limb of the curve is markedly influenced by the light intensity. At the flash intensity the decrease in blueing is evident at much lower doses than in the case of the lower intensities.

Search for a Potassium Compartment in the Human Red Cell Membrane

The present experiments are concerned with the search for a potassium carrier in the membrane of the human red cell. From studies on the efflux of potassium-42 from human red cells, Solomon and Gold[1] concluded that the cell contained its intracellular potassium in two separate compartments. The larger compartment was assumed to contain 41·6 m.eq. potassium/l. blood; the smaller compartment was assumed to contain 1·75 m.eq. potassium/l. blood[2], and to reach its peak specific activity about 1·5 hr. after potassium-42 was added to the system. Fig. 1 shows an analogue computer curve giving the time course of the predicted relative specific activities of the three compartments under the present experimental conditions. In order to determine whether the smaller compartment could be identified with the membrane phase, the kinetics of the uptake of potassium-42 by the cellular membrane have been studied over the time period of a few minutes to six hours. They have failed to reveal the presence of a significant potassium-containing compartment within the membrane phase. Since the time resolution of the present experiments is about three minutes, no information is available about processes which may be complete in shorter times.

Human red cells, suspended in plasma diluted with buffer (Ref. 2, Table 1) to form a suspension containing about 20 per cent cells, were incubated with potassium-42 in the usual manner[2]. Periodically, 1-ml. samples of the blood suspension were withdrawn from the incubation bath, and a small amount of rubidium-86 was added. The sample was then poured on to a siliconized 'Milli-pore' filter, which is characterized by pores too small to pass red cells or hæmolysed red cell membranes. The cells were then hæmolysed by the addition of a 5-ml. portion of water, and suction was applied to remove the hæmolysate. This process was repeated and the material adhering to the filter was then washed once with 5 ml. of normal buffer. The total procedure required 2–3 min. The filter and adhering membranes from two separate 1-ml. samples taken at the same time were then combined for counting. Simultaneous determinations of the potassium-42 and rubidium-86 radioactivities were made in a gamma-ray spectrometer. Since the washing procedure did not remove the suspension medium quantitatively from the membranes and the filters, the rubidium-86 radioactivity was used for correcting for the adherent medium. The remaining potassium-42 after correction was assumed to comprise all the membrane potassium-42 together with a small amount of trapped potassium-42 from the large intracellular potassium compartment.

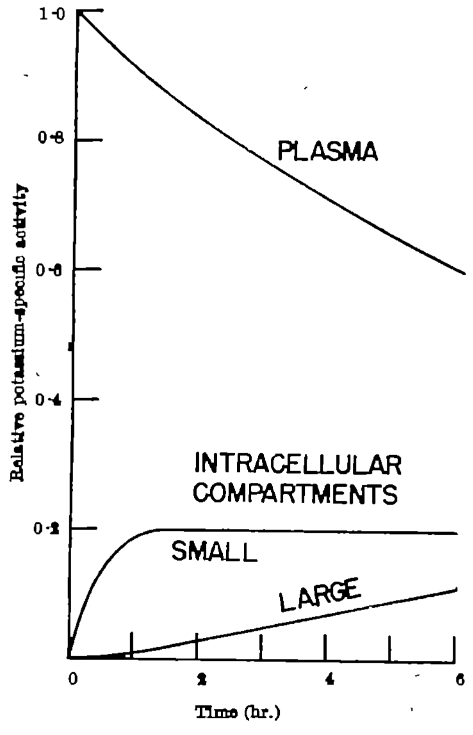

Fig. 1. Analogue computer curve showing predicted relative specific activities for potassium-42 uptake in large and small intracellular compartments

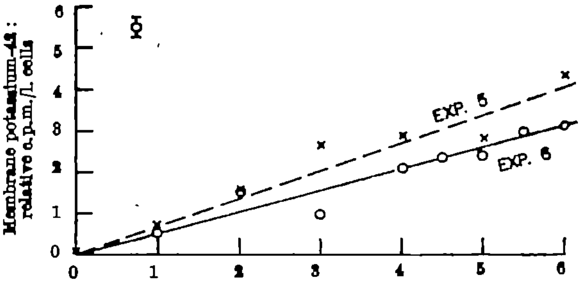

Fig. 2. Uptake of potassium-42 by human red cell membranes. The curves have been drawn by eye. The units of potassium-42 are arbitrary and refer to a fixed size of sample. The statistical counting error is shown in the top left corner

Control experiments in which hæmoglobin was measured photometrically demonstrated that hæmolysis was at least 97 per cent complete under these conditions. In three other control experiments, when plasma solutions containing potassium-42 and rubidium-86 (with inorganic concentrations chosen to simulate experimental conditions) were poured over blank pieces of 'Milli-pore' filter paper, the ratio of potassium-42/rubidium-86 trapped in the filter paper was found to be 1·0 ± 0·1.

The results of two typical experiments of a series of six are given in Fig. 2. It will be seen that the uptake is approximately linear, with no sign of a maximum at 1·5 hr. The kinetics are comparable with the kinetics of the large intracellular compartment, and the uptake could be accounted for completely on the basis of 0·3 per cent of the intracellular potassium remaining with the membrane phase. It is concluded that the membrane phase, as prepared under the present conditions, does not account for a small intracellular potassium compartment with kinetics comparable to those shown in Fig. 1.

The potassium-42 content of the membrane can be converted into total potassium uptake on the assumption that all the membrane potassium-42 is derived from the plasma and is accompanied by non-labelled potassium in the same proportion as the average present in the plasma. This leads to uptakes of 5 and 3·5 μeq./l. cell hour for experiments 5 and 6 respectively, which are very small compared with the predicted small compartment uptake of 2 m.eq./l. cell hr. It can be concluded that the exchange of extracellular potassium with the membrane phase must proceed at a rate less than about 5 μeq./l. cell hr., or that the membrane potassium must exchange with its environment in a period short compared with three minutes.

Solution of Mineral Phosphates by Soil Bacteria

The mechanisms by which soil micro-organisms dissolve insoluble mineral phosphates and make them available to plants is largely unknown, therefore research was undertaken to investigate these processes.

Phosphate-dissolving bacteria and fungi were isolated from soil dilutions by a modification of Gerretsen's technique[1] using carrot extract agar containing finely crystalline hydroxyapatite, precipitated by the addition of calcium chloride and di-potassium phosphate at 50° C. and afterwards adjusting the *p*H to 7. A strain of *Escherichia freundii* was selected for studying the mechanisms of solubilizing the hydroxyapatite, since it dissolved large amounts after 24-hr. incubation. A minimal medium containing 1·0 per cent glucose, 0·05 per cent yeast extract and mineral salts was devised and hydroxyapatite was precipitated in the agar as previously described. Zones of solubilization appeared around individual colonies after 24–48 hr. growth at 25° C. (Fig. 1) wherever the organism produced acids from fermentable carbohydrates (Table 1).

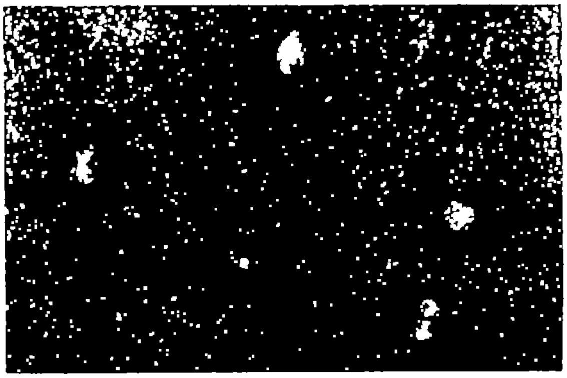

Fig. 1. Clear zone of phosphate solubilization around colonies of *E. freundii* on a minimal medium in which hydroxyapatite has been precipitated at 50° C. (× 4·5)

E. freundii grown in the minimal liquid medium for three days at 25° C. completely dissolved hydroxyapatite (220 μmgm. P/ml.)[2] both aerobically and anaerobically. The organic acids in the culture supernatant were identified by paper chromatography. Volatile acids were converted into hydroxamic acids[3], and thus formic, acetic and propionic acids were detected. The non-volatile acids were determined by the method of Ladd and Nossal[4] and included large amounts of lactic acid with smaller quantities of glycollic, fumaric, adipic and succinic acids. The lactic acid[5] represented about 85–100 per cent of the non-volatile acids (Table 2).

Table 1. Fermentation and Solubilization of Apatite by *E. freundii* in the Presence of Various Carbohydrates

Carbohydrate supplied	Fermentation	Solubilization of apatite
Glucose	*A* + *G*	+
Maltose	*A* + *G*	+
Glycerol	*A* + *G*	+
Sucrose	Growth only	−
Erythritol	Growth only	−

A, Acid; *G*, gas; +, solubilization; −, no solubilization

Table 2. Acid Production by *E. freundii* (μeq. acid/ml. of culture supernatant)

Determination	Aerobic		Anaerobic	
	Phosphate supplied		Phosphate supplied	
	KH_2PO_4	Apatite	KH_2PO_4	Apatite
Total acidity	14	14	25	22
Non-volatile acidity	8	9	17	15
Lactic acid	7·5	8·2	14·3	16

Johnson[6] showed that all these acids solubilize calcium hydrogen phosphate and calcium phosphate, the α-hydroxy acids being among the most reactive. Laboratory tests indicated that 1,200 μmgm. lactic acid was sufficient to bring 220 μmgm. phosphorus into solution. Solution occurred almost immediately and showed no increase after three days standing. Therefore lactic acid alone from this bacterium could have dissolved the apatite. On nutrient agar this organism produced golden-coloured intra-colonial crystals identified as calcium carbonate, as described by Hewitt[7] for *E. coli*.

Numerous other phosphate-dissolving organisms have been isolated. From Waite Institute soil 291 bacterial isolates were made, of which 184 grew on the minimal agar and 84 showed digestion zones varying from 1 to 10 mm. in diameter around individual colonies. In all cases solubilization was accompanied by a fall in *p*H, the lowest value recorded being 4·5. An even higher percentage of phosphate solubilizing bacteria were isolated from the rhizosphere of plants. Many of the organisms irreversibly lost their ability to dissolve phosphate after a few subculturings. After a further period of incubation numerous cultures precipitated calcium salts over the whole of the cleared areas. With one strain of *A. niger* a band of reprecipitation followed closely behind the zone of solution.

Further results have shown that the finer the phosphate particle the more easily it was digested by the organisms. In an experiment where ferric phosphate was incorporated as the insoluble phosphate source, a marked blackening of the particles by numerous organisms occurred. This was shown to be due to hydrogen sulphide production by these organisms. The hydrogen sulphide presumably reduced ferric phosphate to black ferrous sulphide with the release of phosphate.

The importance of these organisms in the soil is difficult to assess but it seems that a local accumulation of lactic acid and hydrogen sulphide from microbial metabolism are at least two biological products important in rendering insoluble phosphates available. Research is continuing on other bacterial and fungal isolates.

I wish to thank Mrs. L. E. R. Rogers for taking X-ray patterns and identifying the precipitate from calcium chloride and di-potassium phosphate as very finely crystalline hydroxyapatite.

Pathway of the Synthesis of Fucose from Glucose in *Klebsiella aerogenes*

IT is possible to obtain evidence for the synthetic pathway of a monosaccharide by determining its isotopic labelling in a suitable polysaccharide which has been produced from a labelled substrate. Experiments were undertaken to determine the synthetic pathway of fucose using a fucose-containing extracellular bacterial polysaccharide which was produced from labelled glucose and methionine as the sole carbon and energy sources.

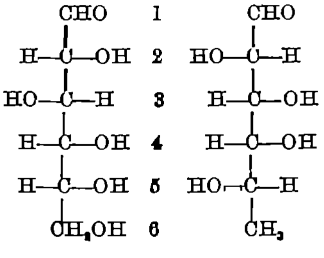
A washed suspension containing about 0·5 mgm. total cell nitrogen per ml. of a slime-forming strain of type 54 *Klebsiella aerogenes* (*A*3 '*S*1') was prepared from a nitrogen-deficient solid medium[1]. It was aerated for 6 hr. at 30° in 250 ml. of a medium containing 0·1 per cent glucose, 0·001 per cent methionine, 0·001 per cent magnesium chloride, 0·0001 per cent calcium chloride and 0·2 *M* sodium phosphate–potassium phosphate buffer *p*H 7·2. The extracellular type-specific polysaccharide was isolated, purified, hydrolysed and the component sugars (D-glucose, D-glucuronic acid and L-fucose) isolated as described previously[2]. The labelling on each carbon of glucose was determined using the *Leuconostoc mesenteroides* method[3] and on C6 of glucuronic acid by decarboxylation with hydrochloric acid[4]. Fucose was degraded by periodate oxidation to give formic acid (C1–4) and acetaldehyde (C5–6). The acetaldehyde was oxidized to acetic acid which was degraded to give C5 and C6 separately[3].

Experiments using unlabelled glucose and $^{14}CH_3$-labelled methionine (100 μc.) as the carbon and energy sources for synthesis showed little radioactivity incorporated into the polysaccharide (less than 0·01 per cent conversion) and no increased labelling of the methyl group of fucose compared with the rest of the polysaccharide. This result indicated that fucose is probably not formed by methylation of the corresponding pentose. Experiments using unlabelled methionine and either glucose-1-^{14}C or glucose-6-^{14}C (200 μc.) gave a yield of radioactivity in the purified polysaccharides of 12·1 and 13·2 per cent respectively. The distribution of carbon-14 in the component sugars is shown in Table 1.

Table 1. PER CENT DISTRIBUTION OF RADIOACTIVITY IN MONOSACCHARIDES DERIVED FROM TYPE 54 *Klebsiella aerogenes* POLYSACCHARIDE AFTER INCUBATION WITH GLUCOSE-1-^{14}C OR GLUCOSE-6-^{14}C

Carbon atom	Glucose-1-^{14}C			Glucose-6-^{14}C		
	Glucose	Glucuronic acid	Fucose	Glucose	Glucuronic acid	Fucose
1	68·7	—	—	13·7	—	—
2	1·2	—	—	1·4	—	—
3	5·6	—	—	3·7	—	—
4	3·0	—	—	6·7	—	—
5	1·1	—	1·6	1·2	—	0·9
6	19·0	18·6	20·3	72·9	69·2	71·5
Average 1–4	19·6	—	18·5	6·4	—	5·2

It is evident that the distribution of labelling in the three sugars is very similar, so far as the experimental method can determine. This suggests that glucuronic acid and fucose are probably derived from glucose without a splitting of the carbon chain and without a reversal of the molecule. The result with glucuronic acid was expected from a knowledge of its synthetic pathway[5] and agrees with previous results obtained with *Streptococcus pyogenes*[4]. However, conversion from D-glucose to L-fucose without splitting or inversion of the carbon chain involves a Walden inversion of three carbon atoms as well as reduction of C6 to a methyl group—a very surprising metabolic pathway.



D-Glucose L-Fucose

Similar results showing a conversion of D-glucose to L-fucose without a change in carbon chain have been obtained recently by Heath and Roseman (in the press). They degraded the fucose of the extracellular polysaccharide by periodate oxidation of the benzimidazole compound in order to get C1, 2, 5 and 6 separately. As their results are reported in detail, those presented in this communication will not be published further.

The experiments described above were carried out during 1955 at the Berkeley campus of the University of California. I am indebted to the Rockefeller Foundation for a fellowship during this period.

Effect of Gamma Rays on the Sprouting of Stored Mangolds

GAMMA radiation, which has previously been shown to prevent sprouting in potatoes[1], onions[2] and carrots[3], has now been found to prevent the sprouting of stored mangolds (*Beta vulgaris*). Recently harvested mangolds of the variety Orange Globe, from which the leaves had been removed leaving 2 in. of leaf-stalk, were irradiated in batches of five with a cobalt-60 source giving a dose-rate of 100 rads per min. After treatment on November 7, 1956, the mangolds were bedded in damp sand in an unheated building. On April 8, 1957, the mean lengths of the sprouts were 5·7, 3·2, 1·5, 0·0, 0·0 and 0·0 in. on the batches given 0, 5,000, 10,000, 20,000, 30,000 and 40,000 rads, respectively. Some of the aphid species that transmit viruses of sugar beet and mangold crops survive through the winter in clamps and multiply in the spring on the developing sprouts of mangolds[4]. This experiment was part of a programme of research to find a method of preventing the aphid vectors from over-wintering in this way.

Effects of Red and Far-Red Radiation on Seed Germination

DURING a recent study of the effect of continuous and short illumination on the germination of *Amaranthus retroflexus* seeds[1], three new facts concerning the effect of red and far-red radiation have been found.

Amaranthus retroflexus seeds germinate to the extent of about 50 per cent in darkness at 37° C. within 48 hr. with no subsequent germinations. But a single illumination of 1,000 ft.-candles for 2 sec., given at any time after 48 hr., causes 100 per cent germination within 24 hr. of illumination. The ability of the seeds to respond to such a short light stimulus is not diminished by several months of imbibition. If, instead of darkness, the seeds were kept for the first two days in continuous high-intensity far-red radiation, they did not respond even to a much stronger light stimulus. The ability of these seeds to react to a short irradiation was regained if they were placed for a certain period in darkness (Fig. 1, curve *a*). If, however, after being in the dark, the seeds were illuminated again with continuous far-red radiation, the ability to respond to short illumination diminished again (Fig. 1, curve *b*). This could be repeated several times. (For technical reasons very short illuminations (up to 60 sec.) were given with white instead of red light. But each kind of experiment was repeated at least once with pure red light, to ascertain that the effect of the short illumination was really that of its red component.)

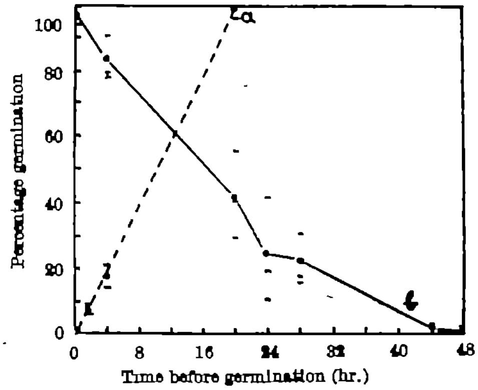

Fig. 1. (*a*) The seeds were kept in continuous far-red light for two days and then removed to darkness. After various intervals, which are given on the abscissa, three dishes containing 100 seeds each received an illumination of 3 sec. at 1,000 ft.-candles of white light. Germination was counted after a further 24 hr. in darkness

(*b*) The seeds were kept in continuous darkness for the first two days and then removed to continuous far-red light. After various intervals in far-red light, the dishes were illuminated as above and removed to darkness for a further 24 hr. The far-red light was filtered out of a source giving an intensity of 1,000 ft.-candles at the level of the seeds

In contrast to the usual reversible red – far-red effect[2], red in this case is not effective immediately after continuous high-intensity far-red. Some sort of prolonged dark reaction is needed to restore the response of the seeds to red light. Thus, the effect of prolonged high-intensity light on plant development is not due only to photosynthesis, as was supposed by Liverman[3] and others, but has been shown to be directly involved in the red – far-red reaction. This may also explain why Stolwijk and Zeevaart could not demonstrate an inhibitory effect of red light on the flowering of *Hyoscyamus niger* when the red light was used after prolonged infra-red irradiation.

The reversal of the effect of red light by far-red illumination was less effective if the latter was given immediately after the red than if a short interval of one or two minutes was allowed between them (Fig. 2, curve *a*). This indicates the existence of a dark reaction during the interval. The effect of temperature on this red – dark – far-red reaction was investigated. First it was ascertained that placing the seeds for 5 min. on ice did not affect dark germination, nor the sensitivity of the seeds to red light.

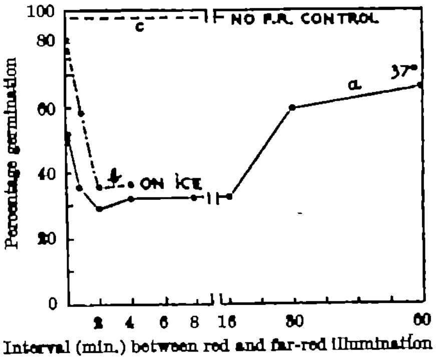

Fig. 2. Effect of temperature and time-interval between application of red and infra-red illuminations. (*a*) During the interval between illuminations the seeds were kept at 37° C. (*b*) During the interval between illuminations the seeds were kept on crushed ice. (*c*) Seeds receiving no far-red illumination

The illuminations used were 2 sec. of white light of 1,000 ft.-candles and then, after various intervals, 30 sec. of far-red light filtered out of the same source. The dishes with the seeds were kept for 48 hr. in the dark at 37° C. The seedlings were removed in blue light and the remaining non-germinated seeds were divided into two lots, one of which was placed on crushed ice for the period of five minutes. Illuminations, as described above, were applied during the 5 min. in such a way that the far-red was given just before the end of this period. The control lot was illuminated in the same manner but at 37° C. The results of these experiments are summarized in Fig. 2. It is evident from these results that low temperature further delayed the maximum effectiveness of far-red irradiation in reducing germination. The results, therefore, confirm the existence of a dark reaction sensitive to temperature in addition to the photochemical one. This is in contrast to the findings of Borthwick *et al.*[2], who could not demonstrate any temperature effect on the reversible red – far-red reaction when the seeds were illuminated at low temperature.

From the curve for the control seeds (Fig. 2, curve *a*) it is also evident that on further prolongation of the dark period, a point is reached when far-red light is completely ineffective in reversing the effect of red light[3,4].

A further effect of red and far-red radiation was found when the seeds were germinated at 26° instead of at 37° C. The seeds received short illuminations of 1,000 ft.-candles of white light for 1 min. once every day on the first, second and fourth days. Control lots received a single illumination only on one of these days (Table 1). From Table 1 it is evident that at 26° the sensitivity of the seeds to short illuminations is only developed fully by the fourth day. Illumination given prior to that day diminishes the effect of a subsequent illumination. Further experiments showed that this inhibition by a 'premature' illumination was caused by the red component of the light used. It is suggested that the effect of the 'premature' illumination may be analogous with the short interruption of darkness in long-day plants. A further study of this problem is in progress.

Table 1. GERMINATION OF *Amaranthus retroflexus* SEEDS AT 26° C

Treatment	Percentage of germination
No illumination	20 ± 2*
Illuminated 60 sec. with 1,000 ft.-candles on	
1st day	21 ± 2
2nd day only	53 ± 8
1st and 2nd days	39 ± 2
4th day only	96 ± 4
1st, 2nd and 4th days	69 ± 1
2nd and 4th days	68 ± 1

* ± maximal range

This investigation has been carried out under the guidance of Prof. M. Evenari, and I thank him for his interest and help during the course of this work. This communication is based on a Ph.D. thesis to be submitted to the Hebrew University, Jerusalem; and a detailed report of the investigations will be published elsewhere.

A Quantitative Comparison of Sulphydryl Content and Formazan in the Tissues of the Pea Radicle

SEVERAL workers have discussed the tetrazolium indicators as possible histochemical reagents for SH-groups[1–4]. Experiments by Roberts and Lucchese[5] indicated a positive correlation between the histochemical localization of protein-bound SH-groups and triphenyl tetrazolium chloride reduction.

Experiments were conducted to determine the possible quantitative relationship between *in vivo* SH and formazan in segments of the radicle of *Pisum sativum* L. (var. Express). 5-mm. segments were excised from seedlings of various age-groups at the same stage of tissue differentiation, as reported by Féjer[6]. Quantitative determinations were conducted on the SH-content of the samples by the amperometric titration method[7]. Quantitative determinations of reduction of tetrazolium by the tissues were carried out following incubation of the samples for 20 hr. in a medium consisting of Sorenson's phosphate buffer (*p*H. 7·4) at a final concentration of $10^{-1} M$, tetrazolium at a final concentration of $10^{-3} M$, and sodium succinate neutralized with sodium bicarbonate (*p*H 7·4) at a final concentration of $10^{-2} M$. On the basis of the experimental values of SH-content, the equivalent amount of intracellular formazan was determined by calculation. The results are given in Table 1. All values are expressed in 10^{-3} mgm./100 mgm. fresh weight of sample. The experimental results revealed that radicle segments from older plants contained a higher concentration of total SH than young plants at the same stage of tissue differentiation. On the other hand, experimentally determined formazan values were higher in the segments of radicles of young plants and decreased sharply in seedlings from two to six days old.

Table 1. COMPARISON OF SH CONTENT AND EXPERIMENTAL AND CALCULATED VALUES OF FORMAZAN CONTENT OF PEA RADICLE TISSUES*

Age of plant (days)	Total SH	Total formazan	Formazan calculated from SH content
2	22	354	111
4	40	162	202
6	75	63	379
8	95	58	481

* All values are expressed in 10^{-3} mgm./100 mgm. fresh weight of sample.

Although previous workers have indicated the possibility of using tetrazolium indicators as histochemical reagents for SH-groups, the present experiment did not reveal a positive correlation between total SH and formazan content in segments of pea radicles. On the contrary, SH and formazan values were inversely proportional in all determinations. Since determinations on segments excised from young plants revealed considerably more formazan than SH, it is unlikely that SH-groups played a part as a substrate in the reaction. These groups are probably present as protein-bound SH-groups of the apoenzyme. It can be demonstrated that the endogenous substrate is exhausted after approximately 6 hr. incubation and reduction of tetrazolium ceases. However, reduction of the indicator will be resumed on the addition of succinic acid as a substrate. Sulphydryl groups are effective in reducing tetrazolium only at pH values[2-4] in excess of 10·0. Findlay[3] reported a 100 per cent efficiency in the *in vitro* reduction of neotetrazolium at pH 12·6. All the present results were obtained from incubation media buffered at pH 7·4. The SH concentrations employed by Roberts[5] in determinations of *in vitro* reduction of tetrazolium by SH-groups were considerably in excess of physiological concentrations encountered in cells.

It is interesting to note that segments of radicles of the same state of differentiation exhibited considerable difference in SH and formazan values from plants of different age-groups. Similar differences have been reported in determinations of free amino-acids, isoelectric point[9], and certain sulphur-containing compounds[8] in segments of radicles from plants of different age-groups. These results have been observed in other members of the Leguminosae and appear to be specific for this family[10]. Therefore, it is important to point out that the reverse trend of SH and formazan is a special case; in certain other plant families a closer correlation between these values will be observed. The Leguminosae family was chosen to illustrate that the histochemical pattern does not result from a direct reaction between SH and tetrazolium, but to direct attention to the importance of SH in the enzymes involved.

Acknowledgment is made to Mrs. Olga Féjer for SH determinations.

Vesicular-Arbuscular Mycorrhizas in Apple Seedlings

MOSSE has described the formation of vesicular-arbuscular mycorrhizas in apple seedlings grown in sterilized soil to which sporocarps of a species of *Endogone* were added[1]. She states that "no attempt was made to sterilize the sporocarps since their loose structure makes this impossible". Thus the identity of the endophytic mycelium in the apple roots with that of *Endogone* could not be proved.

We have been able to show that a similar vesicular-arbuscular endophyte in roots of *Allium ursinum* and other plants (including *Fragaria vesca*) is a species of *Pythium*[2], closely resembling *P. ultimum*.

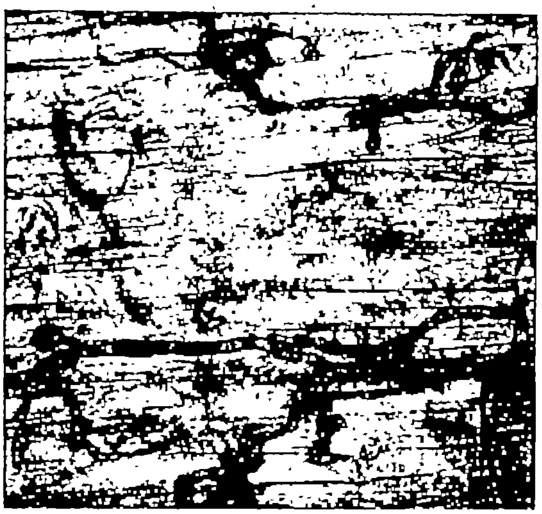

Fig. 1. Hyphae of *Pythium ultimum* (isolate from *Allium ursinum*) in roots of inoculated apple seedlings (8 weeks old). Note irregular, intercellular hyphae, bearing vesicles, and intracellular, occasionally septate, branches. Arbuscules do not develop until later

Inoculation experiments and the use of Harrison's[3] direct-observation method of isolation of the endophyte leave no reasonable doubt that the *Pythium* isolate is able to produce a vesicular-arbuscular mycorrhiza in association with the roots of a number of unrelated plants. Since Mosse[4] considered that similar endophytic mycelia in roots of strawberry and apple were attributable to an unidentified species of *Endogone*, we investigated the effect on apple of isolates of *Pythium*, including that from *A. ursinum* and one of *P. ultimum* from lettuce. Surface-sterilized apple pips were sown in steam-sterilized soil (John Innes No. 1 potting soil) inoculated with sand and oatmeal cultures of the *Pythium* isolates. The pots were stood in sterilized dishes in a temperate greenhouse. The soil was covered with a ½-in. layer of sterilized sand, and the pots were watered with sterile water. Uninoculated controls remained free from infection throughout the experiment. During the early stages of germination a few seedlings, inoculated with the lettuce isolate of *P. ultimum*, damped-off but the rest survived. Four weeks after germination of the seedlings the fungus became established as an intercellular mycelium with a few intracellular branches. Three-month-old seedlings had reached the stage shown in Fig. 1. Ovoid or globose vesicles were formed both outside and inside the roots. Branched, irregularly crenate, sometimes septate, hyphae were widespread in the cortex. The endophyte was strikingly similar to that figured by Mosse. *Pythium* was re-isolated from these seedlings by Harrison's direct observation technique.

Infected seedlings were noticeably taller and sturdier than the uninfected controls, as was noted by Mosse in her experiments.

The close similarity between the effects produced by inoculation of apple seedlings with *Pythium ultimum* in our experiments and those associated with the presence of *Endogone* in Mosse's work is very striking. Either both these unrelated fungi assume the same form on entry into apple roots, or *Pythium* was present in or on the unsterilized sporocarps of

Endogone used by Mosse. Further work on these *Pythium* isolates is in progress in this laboratory.

Transmission of Trophic Stimuli along Developing Nerve Fibres

In the development of the nervous system of the vertebrate embryo, the spinal nerves grow outwards to the developing limb-buds. Once within the limb rudiment, nerve fibres apparently convey some trophic stimulus to their cell bodies, at the levels of the brachial and lumbar plexuses. This influence can be demonstrated by removal of a limb on one side of an embryo, when both the sensory neurones of the dorsal root ganglia[1] and the motor neurones of the ventral horns within the cord[2] have been shown to be fewer in number on the operated side.

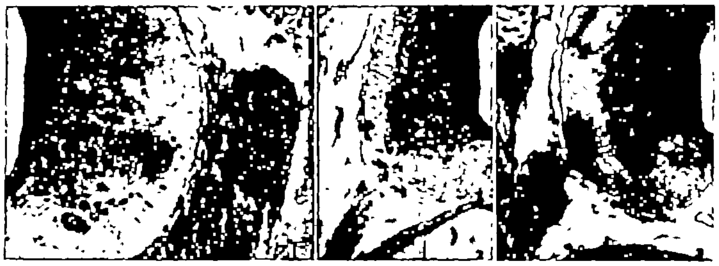
Recent experiments by us on the toad *Xenopus laevis* show something of the means by which this influence is exerted. We have interfered with its normal operation at lumbar levels in the following ways:

(1) Removal of the hind limb-bud, followed by measures to check any subsequent regeneration, for example, by grafting head skin over the limb area.

(2) Insertion of a barrier between the outgrowing spinal nerves and the limb-bud. Into a horizontal cut through the larva below the notochord a thin lamina of mica was inserted, over the surface of which ectoderm regenerated. After a few days the mica was removed; a permanent cleft then remained. The lumbar nerves can then only reach the limb by a tortuous path around the borders of the cleft. The obstacle is not always overcome, and in such instances the limb develops without innervation.

(3) Treatment of the limb area with the nitrogen-mustard methyl-*bis* (beta chlorethyl) amine hydrochloride. One of us[3] has already shown that local application of this substance at 1 : 500 dilution will suppress the development of the hind-limbs. We have now shown that the effect of the treatment extends beyond the limbs to the dorsal root ganglia of the lumbar region, where their cell bodies may undergo degeneration. The corresponding ventral roots remain unaffected (Figs. 2 and 3).

The particular effects of these experiments on the ventral horn call for notice. This centre normally develops in two stages. First, groups of neuroblasts are formed at the ventro-lateral margin of the grey matter of the cord in the lumbar region. Later, a compact group of these cells differentiates into bipolar neurones (Fig. 1). The nucleus and nucleolus then enlarge, and Nissl substance is laid down within the cytoplasm.



Figs. 1–3 show transverse sections through part of the spinal cord of tadpoles of *Xenopus laevis*

(1) Normal larva, 35 mm., through level of the tenth spinal ganglion, showing ventral horn. × 120

(2) Larva, 34 mm. long, 29 days after treatment of limb-area with 1 : 500 nitrogen-mustard. The ninth spinal ventral root is shown; the corresponding dorsal root ganglion has been destroyed. No ventral horn has developed. × 85

(3) Larva, 46 mm. long, 44 days after treatment of limb-area with 1 : 500 nitrogen-mustard. The much-reduced tenth spinal ganglion is shown; again no ventral horn has developed. × 85

The ventral horn will develop as far as the neuroblast stage in the absence of limbs and of dorsal root ganglia. The further stage of differentiated neurones is only attained, however, if a nerve has reached the limb, and also provided that sufficient cells of the lumbar dorsal root ganglia still remain. These facts, which follow from the results of experiments in groups (2) and (3), suggest that: (*a*) some stimulus which originates in the limb is necessary for the differentiation of neurones in the ventral horn; (*b*) this stimulus is transmitted along fibres of the dorsal root ganglia.

In larvæ in which a limb was removed at an early stage, a small bud usually regenerates. Four weeks after the operation, the dorsal root ganglia on the operated side contain about half their normal number of cells. Yet within the cord there is here little difference between the ventral horns on the two sides. It thus seems that the stimulating effect of the limb is of the nature of an induction, and one in which the final result is largely independent of the magnitude of the original stimulus.

Not only does the normal formative stimulus from the limb travel to the cord along afferent fibres, but also the degenerative effect after treatment of the limb-area with nitrogen-mustard is propagated along the same channels and in the same direction. In both instances the action appears to be independent of the ventral root fibres. It seems, however, that the latter can transmit formative stimuli of another kind in an efferent direction. This evidence comes from the development of the jaw musculature in larval *Xenopus*[4]. By the use of an azo dye-coupling reaction, it has been shown that groups of neurones within the hind brain show a positive reaction for cholinesterase a day before their axons finally reach the fibres of the developing jaw muscles, when the enzyme first appears at neuro-muscular junctions. Preparations from larvæ at this stage show how the distribution of the enzyme follows the course of the nerve fibre. This sequence is most easily explained by assuming the transmission of a substance, possibly the enzyme itself, or an immediate precursor, along the developing axon.

The brilliant experiments of Levi-Montalcini[5] and her collaborators[6] have shown that chemical substances, apparently proteins, can stimulate the development of fibres from dorsal root and sympathetic ganglia of the chick, both in the intact embryo and in tissue culture. Some years ago, one of us[7] demonstrated that in cultures of spinal ganglia of the chick, vacuoles taken in at the nerve tip rapidly travel along the fibre towards the cell-body, although in cultures of the spinal cord itself movement along the axons in the zone of outgrowth is irregular and without a general trend.

It is likely that trophic stimuli are transmitted within the developing nervous system by the passage of substances along the growing nerve fibres. The present evidence suggests that in some instances they travel in the same direction as that in which the nerve impulse will be conveyed in functional life.

Development of Isolated Female Larvæ of the Potato-Root Eelworm (*Heterodera rostochiensis* Woll.)

Tyler[1], following the observations of Byars[2] and Gabriel[3], conducted an experiment to determine whether the root-knot nematode, *Heterodera marioni* (Cornu) (now *Meloidogyne* sp.), could reproduce in the absence of males. Lines were maintained from isolated females through as many as twelve generations. Since *Heterodera* and *Meloidogyne* are closely related genera of the subfamily Heteroderinae, the possibility of such reproduction (parthenogenesis or syngonism) occurring in the potato-root eelworm, *Heterodera rostochiensis* Woll., was investigated.

Small tubers of Majestic potato were surface-sterilized and all 'eyes' removed. They were then cut into halves and a single larva of the potato-root eelworm was placed on each freshly cut surface. Each half-tuber was then buried in moist, autoclaved sand, one piece in each of a hundred 2½-in. pots, each covered with a glass lid and the sand kept moist by watering with a 20 p.p.m. copper sulphate solution. As controls, twelve similar tuber slices were prepared and about 2,000 larvæ added to each. The pots were kept at laboratory temperature (20–22° C.).

After four weeks the tubers were removed, washed free of adhering sand and examined for cysts. Further weekly examinations were made until the sixth week when, on two tuber slices, single developing females were seen. The control slices by this time bore numerous cysts, many in the yellow stage of development, and containing embryonating eggs. The single isolated cysts were maintained on the tuber slices until the tenth week, at which time they were still white, although a slight browning was detectable. They did not pass through the distinctive yellow stage. No eggs were found when the cysts were opened. 'Giant cells' were present in the tuber tissue associated with developing cysts.

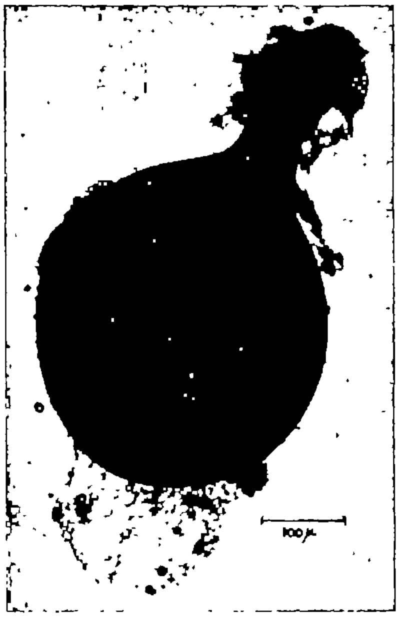

Fig. 1

These results are in agreement with those reported by Fassuliotis[4] and Ellenby[5], who found no embryonated eggs in cysts developing on the roots of separate tomato plants and potato plants respectively to which a single larva had been added. They suggest that parthenogenesis does not occur.

One of the isolated females showed a gelatinous extrusion reminiscent of the egg sac found in other *Heterodera* spp., but not hitherto described in *H. rostochiensis* (Fig. 1).

This work is part of an investigation financed by the Agricultural Research Council. Thanks are due to Mr. S. G. Revell for the photograph of the cyst with the gelatinous extrusion.

Effect of Leaf Rust on Cereal Forage

Few investigators have examined the effect of leaf rust on yield, chemical composition and nutritive value of cereal forage. This situation is unexpected in view of the large acreage of cereals devoted to sheep and cattle grazing in many countries. However, the reviews of Allen[1] and of Chester[2] indicate that invasion of a susceptible host by an obligate parasite such as leaf rust is accompanied by physiological disturbances mediated by chemical change. Murphy[3] found that leaf rust infection of oats, harvested at the boot stage, reduced the yield of forage, altered the chemical composition and delayed maturity except where water-stress occurred. Murphy's observations may apply only to cereal forage at the boot stage of maturity and not necessarily to the much earlier stage of maturity at which cereal forages are grazed in New Zealand and elsewhere. Yarwood[4] observed increased invasion of rust-infected tissue

by fungi, viruses and insects, and measured improved growth-rate of slugs and rats eating rust-infected bean leaves. However, digestion of monogastric animals differs from that of ruminants in several ways, so that Yarwood's observations have limited application to sheep.

Pot experiments were consequently carried out to elucidate some aspects of the leaf rust/cereal forage/ruminant complex. The summarized results are presented in Table 1, which clearly shows the marked reduction in yield of forage caused by leaf rust. Also a reduction in palatability of rust-infected forage was observed in field experiments. The percentage of dry matter in the cereal forage was usually, but not always, increased by rust infection. Henneberg analyses (Table 2) showed that the crude protein and ash content of rust-infected cereal forage was increased, whereas that of nitrogen-free extract and crude fibre was decreased. Furthermore, changes in chemical composition, normal to increasing age or changing season, occurred; but there was a marked lag in chemical change of the rust-infected forage, indicating a real delay in maturity due to rust. Consequently, the hypothesis that leaf rust affects chemical composition mainly by reducing the physiological age is proposed.

The most plausible interpretation is that the altered content of crude protein and crude fibre of rust-infected forage represents improvement of the digestibility and nutritive value. This is at least true for guinea pigs, as was shown by Hall[5], who used rust-infected and rust-free Dun oat forage grown by me. The guinea pigs eating rusted forage grew heavier per unit of time and unit of feed than did those eating rust-free forage. Also there were no short-term toxic effects. This was unexpected as the almost unanimous opinion of farmers, from frequent observation, is that sheep grazing severely rusted cereal or pasture forage, scour, fail to thrive and sometimes die.

There is clearly very good agreement between experimental results and farmers' observations that rust reduces yield of forage and palatability, but marked disagreement on the effect of the chemical change on ruminant thrift. The evidence from field observation is so strong that it cannot be lightly dismissed. Factors not yet considered in experiments so far carried out are doubtless involved. The reconciliation of field-observations and experimental results may follow from experiments measuring, for example, the daily intake of rusted forage, ruminant alergy to rust spores or the effect of changed chemical composition on protein or mineral imbalance.

A fuller report of this series of experiments will shortly be published in the *Journal of Agricultural Science*.

Toxicity of Lithium Salts to Keratin-digesting Insect Larvæ

THE inorganic salts reported to be the most toxic to clothes-moth and carpet-beetle larvæ are the fluorides[1], and these have been used on an appreciable scale in the moth-proofing of wool.

Waterhouse[2] has shown that cations which form insoluble sulphides are detoxified by clothes-moth larvæ by conversion to the sulphides, which are excreted or deposited in the gut wall. Consequently, metals which form soluble sulphides, and which are not normal tissue constituents (such as lithium), may be toxic. Further, since the gut of the clothes-moth is at about *p*H 10, metals forming unstable sulphides which decompose into soluble hydroxides (for example, barium, strontium) could also be toxic. Metals, the sulphides of which decompose into insoluble hydroxides (for example, aluminium, chromium), could be excreted in this form.

We have confirmed the toxicity of salts of barium (chloride) and strontium (chloride, nitrate)[3] to moth larvæ, and find also that lithium salts (sulphate, chloride, hydroxide, citrate) are poisonous. Fully active 21-day old clothes-moth larvæ (*Tineola bisselliella* Humm.) all died in 6–7 days when allowed to feed on fabrics containing 0·2 gm.-ion of lithium, strontium or barium per 10^4 gm. wool (0·1–0·5 per cent by weight of their salts). The weight of wool eaten per larva was 0·2–0·4 mgm., compared with about 2 mgm. of untreated wool consumed by a larva of the same age in 7 days.

Salts of lithium, strontium and barium also protect wool from carpet-beetle larvæ (*Anthrenus flavipes* Le Conte), although their mechanism of metal detoxification differs from that of moth larvæ[4].

Moth larvæ fed on wool containing 1 gm.-ion per 10^4 gm. wool of iron (ferrous sulphate), mercury (mercuric acetate), antimony (potassium antimony tartrate), silver (nitrate), cadmium (acetate), lead (acetate), copper (sulphate), nickel (sulphate) or cobalt (chloride), which form insoluble sulphides, showed 70–90 per cent mortality in 14 days. However, serious damage was done during this period in which the larvæ could satisfactorily detoxify the metals. At a concentration of 1·5 gm.-ion per 10^4 gm. wool, mercury, silver and antimony, but not the other metals in this group, are sufficiently toxic to prevent visible damage to the wool.

Salts of aluminium (potassium aluminium sulphate), trivalent chromium (sulphate), magnesium (sulphate) or calcium (lactate, chloride) at a concentration of 1 gm.-ion per 10^4 gm. wool have no effect on the normal development of the larvæ. Aluminium and chromium hydroxides are probably precipitated in the gut and excreted, excess magnesium possibly being removed in the same way. Sodium (chloride, sulphate) and potassium (chloride, sulphate, tartrate) also have no effect at concentrations up to 5 gm.-ion/10^4 gm. wool.

Bromides and iodides of sodium and potassium are toxic to moth larvæ at a concentration of 2 gm.-ion/10^4 gm. wool, but not at 1·5 gm.-ion/10^4 gm. wool. The bromides and iodides of lithium, strontium or barium are more toxic at the same molar concentrations than the corresponding sulphates, chlorides or acetates. Also, cadmium, magnesium or aluminium, which have little or no effect when incorporated in the diet of moth larvæ as sulphates or acetates at a concentration of 0·5 gm.-ion/10^4 gm. wool, are toxic at this concentration when combined with bromine or iodine. The latter are then at a concentration of 1·0–1·5 gm.-ion/10^4 gm. wool, a level which is non-toxic when these anions are combined with sodium or potassium.

I wish to thank Dr. M. Lipson and Mr. W. G. Crewther for their helpful criticisms and Mr. T. Bath for skilled technical assistance.

A Method of marking Calliphoridae (Diptera) during Emergence from the Puparium

The practice of marking and releasing insects for subsequent capture has been widely adopted in ecological investigations. Studies on the Calliphoridae have been prominent in this field, the various workers adopting a wide range of marking techniques. However, if liberated adult specimens are intended to simulate naturally emerging insects added to the wild population, it is desirable to avoid the preliminary period of cage-life which most marking methods involve. The incorporation of radiotracers in the larval medium[1] is one method by which pre-release handling of adults can be avoided. A second method has been employed in studies on the Australian sheep blowfly, *Lucilia cuprina* (Wied.). This involves the emergence of the flies from puparia covered by an inch of fine, dry sand intimately mixed with 0·5 per cent of a fluorescent dust. Flies which have emerged from such a preparation may readily be identified under ultra-violet light because they retain a quantity of the fluorescent dust on the ptilinal suture and frontalia. These areas of the head are beset with minute scales[2] which become closely crowded after the ptilinum is retracted, and hold the dust particles between them. The puckering of the frontalia on hardening probably also assists the retention of dust.

Provision should be made for the ready exit of emerging adult flies from the culture vessels, as the film of dust on the pulvilli temporarily reduces their ability to climb on smooth surfaces. Surplus dust largely disappears from the bodies of the flies in the first day or so after emergence; but if any is transferred to 'wild' flies in traps, these accidentally marked specimens may be separated readily from liberated flies by their lack of the characteristic vivid frontal pattern. Many marked flies may be detected during exposure of entire catches to ultra-violet light; but critical examination requires that the flies be faced towards the source of the radiation.

Only three of many fluorescent dusts tested have proved entirely satisfactory ('Lumogen' *L* Yellow Orange, 'Lumogen' *L* Light Yellow and 'Lumogen' *L* White; Badische Anilin und Sodafabrik A.G., Ludwigshafen A/RH, Germany). These dusts have irregular particles, mostly less than 2μ in diameter. They also have cohesive qualities, which make them ball and cake, instead of pouring. On the other hand, most of the unsatisfactory dusts tested poured freely like dry sand, and had rounded particles predominantly larger than 8μ in diameter. The size and smoothness of such particles doubtless prevent their entanglement in the scales of the ptilinal suture and frontalia. Particle size, however, is not the only criterion of suitability for marking, as some extremely finely subdivided dusts were not retained on the heads of flies for significant periods.

Cage tests have shown repeatedly that marked specimens are comparable in longevity, fertility and behaviour with untreated controls. High recoveries have been made in trapping experiments. One marked female was recaptured four weeks after field emergence, and a marked male six weeks after field emergence. There is thus no question as to the ability of marked flies to survive in the wild state, nor the persistency of the marking under field conditions.

The marking technique has also been used successfully by colleagues requiring to separate *L. cuprina* individuals of different strains, or treatment groups in cage experiments.

Limited tests have been made on other species of flies. *Calliphora augur* (F.), *C. stygia* (F.) and *Chrysomyia rufifacies* (Macq.) were all marked satisfactorily. Undoubtedly the method will prove applicable to other species of Calliphoridae.

Interspecific Competition

In a recent article about interspecific competition, Williamson[1] quotes a definition of this process by Elton and Miller[2] and adds that "it is difficult to distinguish between some cases that they would call competition and, say, predation". But in our paper it is made clear that the term "competition" was being used only in respect of members of the same species, or between species of the same consumer layer, that is, it excludes such biotic relationships as predator–prey and parasite–host.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk are open to the public* *)

Monday, November 11

British Society for the History of Science, Philosophy of Science Group (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. S. Toulmin: "Newton on Space, Time and Motion—a Reassessment".

Royal Institution, Library Circle (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Mr. H. E. Ironmonger: "The Royal Institution and the Teaching of Science in the 19th Century".

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Dr. H. W. Melville, F.R.S.: "The Changing Functions of D.S.I.R."*

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. D. Lewis: "The Experimental Approach to Life"* (Inaugural Lecture)

Royal Institute of Chemistry, London Section (joint meeting with the Woolwich Polytechnic Scientific Society, at the Woolwich Polytechnic, London, S.E.18), at 7.30 p.m.—Dr. G. G. Freeman: "Silicones".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Mr. Glyn Daniel: "Megaliths of France".

Tuesday, November 12

Institute of Physics, Electronics Group (at 47 Belgrave Square, London, S.W.1), at 5.30 p.m.—Mr. W. E. Willshaw: "Crossed Field Interaction in Microwave Valves".

Institution of Civil Engineers (at Great George Street, London, S.W.1), at 5.30 p.m.—Mr. Jacques Heyman: "Plastic Design of Pitched Roof Portal Frames".

University of London (at the Royal College of Science, South Kensington, London, S.W.7), at 5.30 p.m.—Prof. P. V. Danckwerts: "Chemical Engineering in a University" (Inaugural Lecture)

Institution of Electrical Engineers, London Graduate and Student Section (at Savoy Place, London, W.C.2), at 6.30 p.m.—Mr. J. D. Navey: "Manufacture of Electric Cables".

Royal Society of Medicine, Psychiatry Section (at 1 Wimpole Street, London, W.1), at 8 p.m.—Discussion on "Physiological Measurements of 'Emotional Tension'". Opening Speakers: Dr. Brian Ackner, Dr. Giuseppe Pampiglione and Dr. Peter Sainsbury.

Wednesday, November 13

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Dr. E. Lester Smith: "Biochemistry of Vitamin B_{12}".*

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. M. C. Dukes: "Broad-Band Slot-Coupled Microstrip Directional Couplers"; "The Application of Printed-Circuit Techniques to the Design of Microwave Components"; and "Re-Entrant Transmission Line Filter using Printed Conductors".

Institution of Mechanical Engineers, Steam Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6.45 p.m.—Discussion on "Steam Conditions in Relation to the Size of Units".

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 7.45 p.m.—Concert of Nigerian Talking-Drums, Songs and Dances.*

Wednesday, November 13—Friday, November 15

Institution of Civil Engineers (at Great George Street, London, S.W.1)—Conference on "The Highway Needs of Great Britain".

Thursday, November 14

Royal Society (at Burlington House, Piccadilly, London, W.1), at 10.30 a.m.—Discussion on "The Physics of Water and Ice" opened by Prof. J. D. Bernal, F.R.S.

East Malling Research Station (at Withersdane, Wye College, near Ashford, Kent), at 4 p.m.—Mr. F. C. Bawden, F.R.S.: "Viruses and Virus Diseases" (Amos Memorial Lecture).*

Institution of Electrical Engineers, Utilization Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. L. Abram, Mr. J. B. McBreen and Mr. J. Sherlock: "D.C. Winder Drives using Mercury-Arc Rectifier/Inverters".

Royal Meteorological Society (in the Conference Hall, County Hall, London, S.E.1), at 5.30 p.m.—Mr. H. H. Lamb: "Weather in the Polar Regions" (Popular Lecture for Sixth-form Scholars).

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. H. O. Schild: "Mechanism of Anaphylaxis"* (Ninth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation. Further lectures on November 19, 21, 26, 28 and December 3 and 5.)

Institute of Metals, Metal Physics Committee (at 17 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. T. H. Blewitt (U.S.A.): "The Low-Temperature Deformation of Metals".

Friday, November 15

Biochemical Society (at the Westminster Medical School, Horseferry Road, London, S.W.1), at 2.15 p.m.—Scientific Papers.

Institution of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5.15 p.m.—Mr. G. E. Beck; Flight Lieut. C. M. Moorhen, Mr. P. Houghton, Mr. C. S. Durst, Mr. D. O. Fraser, Mr. T. Gray and others: "Doppler Navigation".

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Prof. J. P. den Hartog: "Vibration—a Survey of Industrial Applications" (Thomas Hawksley Lecture).

Royal Society of Medicine, Radiology Section (at 1 Wimpole Street, London, W.1), at 8.15 p.m.—Dr. G. E. Donovan and Mr. E. Stafford: "Vision, Photography and Electronics in Radiography".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. John Ramsbottom: "Mushrooms, Toadstools and Other Fungi".

Saturday, November 16

British Psychological Society (in the Gustave Tuck Theatre, University College, Gower Street, London, W.C.1), at 2.30 p.m.—Dr. Howard E. Page: "Trends in American Psychology".

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. G. H. S. Bushnell: "The Art of Ancient Peru".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Astronomy—The Secretary of University Court, the University, Glasgow (November 14).

Lecturer (with an honours degree in chemistry) in the Department of Chemistry, Canterbury University College, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, November 15).

Lecturers (3) (with appropriate academic and/or professional qualifications and sound industrial experience) in the Engineering Department (two in Mechanical Engineering and one in Production Engineering)—The Principal, Welsh College of Advanced Technology, Cardiff (November 15).

Assistant Biochemist, Basic grade (with a science degree, preferably with honours in biochemistry or chemistry, or the A.R.I.C.)—The House Governor, The General Hospital, Steelhouse Lane, Birmingham 4 (November 16).

Senior Lecturer in Electronic Engineering at Brighton Technical College, to be responsible for the subject to final degree standard—The Director of Education, 54 Old Steine, Brighton (November 16).

Senior Research Fellow (graduate in mining, physics, mathematics or engineering, with postgraduate experience, preferably in the field of applied mechanics) in the Postgraduate School of Mining, to undertake a study of the mechanics of rock fracture in mining processes—The Registrar, The University, Sheffield (November 16).

Reader in Physical Metallurgy; Reader in Industrial Metallurgy; and a Reader in Electrical Engineering (Heavy Current)—The Registrar, College of Technology, Suffolk Street, Birmingham 1 (November 18).

Principal (with high academic qualifications and wide experience, preferably including experience in industry and in technical education) of the City College of Technology, Liverpool—The Director of Education, 14 Sir Thomas Street, Liverpool 1 (November 20).

Senior Lecturer or Lecturer in Philosophy at the University of Khartoum—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 20).

Head (well-qualified graduate of a British university) of the Electrical Engineering Department—The Clerk to the Governing Body, Battersea College of Technology, London, S.W.11 (November 22).

Imperial Chemical Industries Fellow at Durham or Newcastle-upon-Tyne, for research in Engineering, Chemistry, Physics and allied subjects, including the biological application of chemistry—The Registrar, University Office, 46 North Bailey, Durham (November 23).

Lecturer in the Department of Electric Power Engineering—The Registrar, The University, Liverpool (November 23).

Research Assistant (with an honours degree in physics or engineering or equivalent qualifications) in the Department of Aeronautical Engineering, to take part in initial investigations in (*a*) the construction of a hypersonic shock tube and (*b*) helicopter blade oscillations—The Secretary and Registrar, The University, Southampton (November 23).

Lecturer (with a good honours degree and preferably teaching experience) in Chemistry; and a Lecturer (with a good honours degree and preferably teaching experience) in Physics at the Nigerian College of Arts, Science and Technology—The Council for Overseas Colleges, 1 Woburn Square, London, W.C.1 (November 25).

Research Assistant (interested in physiology, physics or biochemistry) in the Department of Anaesthetics, to work as part of a group engaged in studying the problems of spontaneous and artificial respiration in man—The Registrar, The University, Leeds 2 (November 25).

Research Assistant (with a first- or second-class honours degree in geology) in the Department of Geology—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (November 30).

Lecturer (with a research degree in chemistry) in Chemistry in the Faculty of Engineering, University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 6).

Lecturer in the Department of Pathology—The Secretary, The University, Edinburgh (December 7).

Lecturer (graduate of a British university, or with equivalent qualifications and experience) in Physics at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, December 14).

Lecturer in the Department of Philosophy, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, December 15).

Research Fellow in the Department of Nuclear Physics, Research School of Physical Studies, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (December 31).

Senior Lecturer in Biochemistry at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 31).

Senior Lecturer in Geology at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, December 31).

Director of the Commonwealth Bureau of Helminthology, St. Albans—The Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Bucks (February 15).

Agronomist (with at least a second-class honours degree in agriculture or botany with two years' postgraduate training or experience leading *inter alia* to a sound knowledge of experimental method) in the Department of Agriculture, Uganda, to collect and study herbage plants and to pursue generally the improvement of ley grazing—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/9/020.

Botanist (preferably male, between the ages of 23 and 32, with a good honours degree in botany with postgraduate training or experience in plant breeding, and preferably an agricultural background), at the Rice Research Station, Rokupr, Sierra Leone, to investigate general botanical problems concerned with rice growing in West Africa—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/15/014.

Electro-Encephalograph Recordist, Grade I—The Personnel Officer, St. Thomas's Hospital, London, S.E.1.

Master (with a good honours degree in physics) to teach Physics to university scholarship level—The Headmaster, School House, Rugby, Warwickshire.

Organic Chemist (male, preferably Ph.D.) at the Sheffield Centre for the Investigation and Treatment of Rheumatic Diseases, to work with a team in the steroid field—The Group Secretary, Sheffield No. 1 Hospital Management Committee, Nether Edge Hospital, Sheffield 11.

Physicist (Basic grade), for work with the 15 MeV Linear Accelerator Research Unit or in the Hospital Physics Department—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1.

Physicist, for work concerned with medical applications of radioactive isotopes—The Secretary, Institute of Cancer Research, Royal Cancer Hospital, Fulham Road, London, S.W.3.

Reader; a Senior Lecturer; and a Lecturer in the Department of Applied Physics—The Secretary, Northampton College of Advanced Technology, St. John Street, London, E.C.1.

Research Assistant (Biochemist or graduate with similar qualifications), for investigating chemical aspects in a general programme on mass culture of marine micro-algae—The Zoology Department, The University, Southampton.

Research Officer (female, with an honours degree in bacteriology, microbiology or zoology)—The Secretary, The Research Institute (Animal Virus Diseases), Pirbright, Surrey.

Senior Technician (with good workshop experience) in the Radiotherapy Department, to assist in research on moving beam radiotherapy—The Secretary, Royal Northern Hospital, Holloway Road, London, N.7.

Technical Assistant (graduate in chemistry, biochemistry or physiology), to assist with biochemical research into certain aspects of diabetes—The Professor of Physiology, The Medical School, King's College, Newcastle-upon-Tyne 1.

Technical Sub-editor (with a knowledge of chemistry) for *Chemistry and Industry*—The General Secretary, S.C.I., 14 Belgrave Square, London, S.W.1.

Technician (preferably with some experience of work in a geological laboratory) in the Geology Department, for work covering a wide field involving the preparation of material for teaching and research purposes—Head of the Department of Geology, Chelsea College of Science and Technology, Manresa Road, London, S.W.3.

PRECISION INSTRUMENTS

Spectrograph ***with quartz optical system***

Critical definition is obtained over the entire range of the spectrum. Size of photographic plate 12 in. × 3 in.

A larger instrument can now be supplied giving a 12 in. length of spectrum between 8000A and 2100A.

Full particulars from the Manufacturers:

Bellingham & Stanley Ltd. DEPT. N, 71 HORNSEY RISE, LONDON, N.19

CORPORATE LIFE IN UNIVERSITY EDUCATION

ALMOST from its establishment, the University Grants Committee has emphasized the importance of corporate life as an essential part of university education, returning to this thesis in almost every report since 1921. In 1942 strong support was forthcoming from the British Association Committee on Post-War University Education, which recommended that at least one year of residence in college or in a university hostel should be required of every internal candidate for a first degree, and a further report from the same Committee ten months later noted a general call for better residential facilities at the modern universities. The Association of University Teachers, in its report on University Developments published in 1944, also advocated the one-year residential principle as an immediate objective, with a full residential system of university education as the ultimate objective. Since 1945, moreover, when it was enabled to give capital grants to universities, the University Grants Committee has placed at the disposal of the universities funds for providing halls of residence, as well as playing fields, students' unions and refectories, without which a fuller corporate and social life becomes well-nigh impossible.

Changes since the War have accentuated the need for increasing the provision of student facilities and amenities in Britain quite out of proportion to the increase in numbers of students. The increase in numbers has in itself made it all the more difficult to find satisfactory lodgings for those students who cannot gain admission to a hall of residence and whose homes are too distant from the university for daily travel to be practicable. Again, with the steadily increasing proportion of students who are in receipt of some form of assistance from public funds, there is a growing number drawn from homes where the accommodation is too limited or the tradition of learning too slender for the student to enjoy the conditions he or she needs for effective and strenuous study.

The very dependence of such students upon State scholarships and other public awards, and the competition to gain admission to a university, point to cases of failure in a way that did not formerly arise; but attention is being focused upon the expansion of halls of residence not simply because lodgings and home life have often failed to provide satisfactory conditions, but because of the positive contribution which living in a hostel or hall of residence usually makes to the development of a student. The expanding frontiers of knowledge, the growing content of curricula, and the increasing specialization of courses both in arts and science tend to leave most students too little time or inclination for the development of those wider interests which should be part of their heritage at a university. Both in regard to the expansion of higher technological education and of university education in general, the importance of an adequate broad general education has been freely emphasized, and while there may be wide differences of opinion as to the content of such a general education or where it can best be given, it is widely accepted that an essential part of it is received from contact with fellow students.

In a recent survey of graduates in industry, Political and Economic Planning noted that, in the suggestions made by members of management as to ways in which the universities could do more to meet the needs of industry, stress was laid on the provision of more halls of residence and the bearing of facilities for residence on the development of personality. The building programme for 1957–59 of the universities of Britain in fact includes halls of residence at thirteen universities and university colleges; and the universities are already giving a good deal of attention to the whole question of the bearing of extra-curricular activities on the general development of their students, although most of the modern universities of England and Wales were originally intended for local students and interest in residence has developed differently for each place. Whereas in the younger universities such as Reading, Southampton and Exeter, residence has been regarded as the natural and usual condition of a student's life, in the older civic universities, in large industrial cities, the idea of halls of residence developed empirically and as accretions when students from outside the local population were attracted and found that lodgings were squalid, dear or unobtainable. Again, in Scotland, by the end of the nineteenth century, the original residential system had long been forgotten and a tradition established by which students, if they could not live at home, lived cheaply in lodgings.

It was against this background that the University Grants Committee appointed a Sub-Committee on Halls of Residence, with Prof. W. R. Niblett as chairman, and its report has just been issued*. The report does not encroach on the field covered by the 1948 report on "The Planning of University Halls of Residence", simply urging that the building be designed for the maximum of privacy and quiet, and is perhaps content to dismiss the question of cost rather too completely. As Sir Keith Murray, chairman of the University Grants Committee, remarks in his foreword to the report, at about £1,500–£2,000 a student-place, the cost of such halls of residence appears high, and if substantial sums of public money are to be invested in their provision, a clear view is needed of their objective and of the conditions which determine their success or failure. The Sub-Committee was appointed to make such a fuller study of the educational role of the hall of residence, but the contrast between the figure just quoted and that of

---

* University Grants Committee. Report of the Sub-committee on Halls of Residence. Pp. vi+54. (London: H.M. Stationery Office, 1957.) 3s. net.

£800 for which, according to the Ministry of Education's Bulletin No. 15, places are provided at training colleges for teachers, and the £100 or so for each student place per annum, including capital and maintenance at 1938–39 prices, of the British Association committee is too startling to be passed over without searching inquiry as to the possibility of providing the essentials at something nearer the lower figures.

Having made this comment, it must be said that Prof. Niblett and his Committee have produced an admirable report. The problem is set fairly and clearly against both its historical background and the growing needs of to-day. The functions of the hall of residence are well defined as well as its practical limitations, and aims are conceived with vision as well as realism and in fairness to the main alternatives described to the Committee; while the conditions for success are indicated, there are also practical suggestions offering important opportunities for experiment. Appointed "To consider and report on the nature and importance of the role which should be played by halls of residence in the education of university students, and its relation to other forms of student organization; the manner in which halls of residence should be administered and staffed in order to carry out this role; and the arrangements within universities for formulating policy on these matters and for supervising its execution", the Niblett Committee has made a noteworthy contribution not merely to university policy in this field but also to thought on general education.

While the higher education of intellectually able young men and women, the promotion of learning and research, and the advancement of knowledge, are to-day accepted as three of the most important activities in a civilized community, the responsibility of the university for the liberal education of the student is not everywhere taken seriously enough. The Committee believes that he should mix with his fellows and seniors under conditions which encourage him to appreciate and discuss matters of the spirit and of the intellect at the highest level of which he is capable. The educated man must have come to some real degree of knowledge and begun to work out a philosophy of life, and in the Committee's opinion the hall of residence has a role of great importance in this wider education. Nevertheless, it does not imply that halls can, or should, take from the departments their share of the responsibility for developing close relations between staff and students. Nor does it suggest either that its conclusions will be easy to translate into practice or that there is any universally applicable 'blueprint' for halls of residence.

Despite the growing support for university residence, the proportion of university students in Britain living in halls of residence and colleges has increased too slowly during the past two decades; in 1955–56 only 27·5 per cent of the total of 85,194 university students were in residence, compared with about 24 per cent in 1934–35 out of the pre-War population of 50,090. Merely to maintain the present proportion would require a further 10,000 places during the next decade if the anticipated increase in student population materializes, even if the potential bulge in 1964–67 is disregarded. Moreover, apart from the impossibility of ignoring, in any planned expansion, the question of where the students are to live, there is on every side a demand for graduates who possess, as well as their specialized knowledge, a wide range of interests, initiative, consideration for others, a strong sense of personal integrity and a willingness to take responsibility. To succeed in the fullest sense, a university education must help the student to achieve these qualities. He can scarcely do so without living in comfortable conditions outside lecture hours, or as a member of a social group inspiring loyalty or providing personal contacts which will extend his interests.

The Niblett Committee is convinced of the great educational possibilities of a good hall of residence. It can provide the student with a society to which he really belongs. In it he has the stimulus of free and informal discussion with a wide variety of his contemporaries and the experience of living with others; the friendships he makes and his daily contacts with people from very different backgrounds all extend his social experience without divorcing it from his intellectual life, while the academic influences which surround the resident have time to sink in and become effective.

For all this to be possible, the hall must contain sufficient people able and willing to nourish it intellectually. The prime stress is laid upon the personality and character of the warden; but the support of a senior common room and the leavening of the student body by some exceptionally able members, preferably drawn from a variety of faculties, in each year of the course, are almost equally important factors. Physical conditions too are, of course, significant: it is probably an advantage to the residential student that he sees his seniors at work and insensibly gathers much from them about the best pace and method in study; but the successful halls are those which continually suggest new interests and points of view to their students. The Committee commends, for example, the institution of regular guest nights, when students have the opportunity of meeting interesting and distinguished people—members of their own or other universities, representatives of industry and the professions, or foreign visitors. It also stresses the importance of some element of dignity in the standards of living, such as maintenance of the older social traditions at formal dinners or on guest nights, and it refers to the student's obligations in a hall as well as his rights, and to the way in which he comes to realize that if he withholds his contribution, he diminishes the whole.

As regards practical recommendations and conclusions, the Niblett Committee agrees with the principle frequently expressed to it that the best size for the individual hall is probably 130–150 students, and where experiments are made in grouping halls on neighbouring sites with a number of services in common, each hall should have its own warden and senior common room. On educational grounds, it believes that two years residence in the hall is desirable, for most students admitted to membership, with an arrangement, whenever possible, for membership of the hall to be retained by ex-residents, who would for the rest of their university course or courses have the right to use some of the amenities of the hall. To this end it is suggested that some halls might build up a nexus of lodgings in special relationship with them, in which some third- and fourth-year ex-residents would live. The Committee agrees with the usual practice by which the wardens, rather than the administrative officers of a university, select students for membership of the halls.

As already indicated, a senior common room is regarded as indispensable, and the Committee suggests a proportion of one senior resident member of staff for every twenty students. It was impressed by the value of staff houses, adjacent to the halls, for married members of the senior common room; and to meet the shortage of senior members of common room residing in halls it suggests the appointment of 'graduate assistants' to the warden from among postgraduate students, who might receive whole or partial remission of residence fees in return for social or supervisory obligations within the hall. It also believes that the warden and senior members who live in the hall should be entrusted with a greater share in the government than obtains in some universities, and suggests that the internal government of a hall should normally be the responsibility of a hall council, with the warden as chairman and including as members the senior members of the university resident in the hall, with one or two others—possibly a member of senate and, where appropriate, representatives of the graduate assistants. It is also suggested that a joint committee of university council and senate should meet regularly to consider the policy of the university as a whole on student residence, including its educational implications, on which the wardens should at least be well represented. So far as students are concerned, they should be encouraged to take a full share in the management and government of a hall, including the usual committee of elected students for dealing with junior common room affairs.

The key to the success of the hall as an instrument of education, however, lies in the qualifications, personality and status of the warden; in the Committee's view, the character of the hall is largely determined by what he is and does. Good appointments are essential, but there should also be a continuing stream of able candidates for these posts, which, it is urged, should be of such standing that anyone below the grade of professor would regard the office as promotion. Great effort should be made to ensure that the office of warden is recognized as one of value and importance in the educational as well as in the administrative life of the university, and the Committee is convinced that wardens should, wherever possible, be men and women holding an academic post in the university. Adequate clerical help should be available; and halls of 130 or more, where the warden is also a member of the academic staff, should also be provided with a bursar, responsible under the warden for the administration of day-to-day running of the hall.

The Niblett Committee recognizes frankly the impossibility of offering residence to every student of a British university in the near future, and it discusses with some insight the various means of bringing students living at home and in lodgings more fully into university life. Students should be encouraged to spend as much as possible of their day within the university precincts, and facilities for work, meals and leisure activities need to be provided. While the university union supplies many of these, it cannot afford the requisite privacy nor can it handle the numbers soon to be expected in the universities. The Committee therefore suggests that student houses, each under the leadership of its own warden, might be established near the main buildings of universities to serve as non-residential halls or social and cultural centres for an appropriate number of students who are not members of a residential hall. There is clearly room for experiment in such directions, and also for some further probing of the costs of halls as set forth by the Murray Report in 1948. Meanwhile, the Niblett Committee has gone far to establish the educational importance of halls of residence and to reiterate the University Grants Committee's own conclusion ten years ago that the further provision of halls of residence should be a prime object of university policy in Britain during the next decade.

PHYSICAL OCEANOGRAPHY

Allgemeine Meereskunde

Eine Einführung in die Ozeanographie. Von Günter Dietrich, mit Beiträgen von Kurt Kalle. Pp. viii + 492 + 30 plates. (Berlin-Nikolassee: Gebrüder Borntraeger, 1957.) 56 D.M.

THE physical aspects of oceanography have advanced rapidly since the last comprehensive text-book, by Sverdrup, Johnson and Fleming, was written in 1942; of the references in Prof. Dietrich's book nearly two-thirds are to papers published since then. The proportion of new papers is greatest in the sections dealing with the study of the sea bottom, surface waves and internal waves, geochemistry and biochemistry of the oceans, and oceanographic instruments. The study of tides has been established longer than other aspects of marine research, and although there is as much reference to new work in this chapter as in any other there is twice as much to older work. Everywhere the new emphasis is on the physical and mathematical development of the subject.

The main purpose of the book is to give an insight into all aspects of the physics of the oceans, to emphasize the relations between them and to introduce the reader to specialist literature if he needs it. It also deals with the relation of the physics to the biology. It is meant to be an introduction rather than a handbook. It is written clearly and concisely, and well illustrated with diagrams and pictures. Its tables and graphs are so well chosen that it will serve as a useful reference book.

The effectiveness of modern theoretical and practical methods is illustrated by reference to results obtained with them. The chapter on topography of the sea floor, sediments and morphology describes the results of seismic and echo sounding, coring, and gravity determinations, and discusses density currents, submarine canyons and the history of the oceans. The chapter on physical properties is particularly rich in graphs showing as much as is known about the dependence of the physical properties, including sound velocity and light extinction, on temperature and salinity and other factors. Instruments, energy interchange, currents, circulation, long waves and all other aspects of the subject are admirably dealt with.

To look for faults is being ungrateful, but perhaps it might be better to introduce the idea of a wave spectrum by referring to the now classic paper of Barber and Ursell (*Phil. Trans. Roy. Soc.*, A, 240, 527; 1948) which showed that there was such a spectrum and that the different wave-lengths travelled according to theoretical expectation, instead of starting with Neumann's ideas. It is perhaps reasonable to expect a text-book which summarizes new progress to do as much as possible to preserve the main features of historical development. "The Oceans" by Sverdrup, Johnson and Fleming seems sometimes to be quoted when reference farther back might be more rewarding. Measurement of currents by the electromagnetic method from a moving ship is mentioned, but it would have been useful to refer to the early paper on "The Electrical and Magnetic Effects of Tidal Streams" by M. S. Longuet-Higgins (*Mon. Not. Roy. Astro. Soc.*, Geophys. Suppl., 5, 285; 1949) which makes a careful study of the history of the subject, and to that by M. S. Longuet-Higgins, M. E. Stern and H. Stommel (*Pap. Phys. Oceanogr.*, 13, 1; 1954) which deals comprehensively with the theory. It would also have been useful to refer to Bowden's spectacular demonstration of the practicability of these ideas in the Straits of Dover (*Phil. Trans. Roy. Soc.*, A, 248, 517; 1956).

These are small defects in an excellent book. Its clear and concise style makes it readable by seamen and others not expert in science, and by students who do not read German very well; but it is to be hoped that someone in Great Britain or the United States will translate it, to make it as widely available as possible.

G. E. R. DEACON

FLOW THROUGH POROUS MEDIA

The Physics of Flow Through Porous Media

By Dr. Adrian E. Scheidegger. Pp. xii+236. (Toronto: University of Toronto Press; London: Oxford University Press, 1957.) 110*s*. net.

THIS book is, to a great extent, complementary to a recent book on the flow of gases through porous media (Carman, P. C., "Flow of Gases through Porous Media". Butterworths; 1957), as it deals predominantly with liquids in single and multiphase flow. The approach is a theoretical one and strictly limited to the physical aspects of fluid flow. The method used is that of a review of existing world literature, with exposition of selected main topics in the form of basic differential equations and discussion of particular solutions of each case. The author gathered the material for the book while working with Imperial Oil, Ltd., Canada, and it originated in a compilation of two thousand references on the subject, of which the author has retained a thousand. It constitutes the best available selection, especially because it includes, for the first time, a great deal of non-Western literature.

The survey of the field is very thorough and therefore extremely valuable, even if a critical appraisal of much apparently similar work is often not given. On p. 145, we read, for example, that "the Klinkenberg equation has been tested by Grunberg and Nissan (1943), Calhoun (1956), Calhoun and Yuster (1946), Heid *et al.* (1950), and Collins and Crawford (1953)". It would have been helpful had the author added that at least one of these contributors was not able to verify the equation and had given an opinion on the observed discrepancies in results.

The author devotes one-fifth of the volume to the all-important structural properties and hydrostatics of porous media, together with the flow of fluids in general. A puzzling statement refers to the critical Reynolds number at which the flow becomes turbulent (p. 26). On the authority of a French and Turkish reference, the author states that this critical Reynolds number is reduced if the direction of flow in tubes becomes increasingly curved. However, British and United States practice (as quoted in handbooks) accepts the work of White and Taylor (*Proc. Roy. Soc.*, A, 123, 645; 1929: 124, 243; 1929), which shows that the critical Reynolds's number at which departure from streamline flow takes place increases with the curvature of the tube. There is indeed considerable evidence that, with increasing velocity of flow, streamline flow in curved tubes is maintained much longer than in straight tubes.

In the following chapters, on Darcy's Law and the solutions of the general flow equations, the author is really at home, and the theoretical treatment is excellent. One could only wish that the drag theory of permeability and the general equations for high flow rates could have been more extensively treated, in view of the many empirical equations which have been derived to cover this type of flow. The chapter on multiphase flow gives a scholarly account of the theoretical work available and occupies one-third of the volume.

It is unfortunate that the author has little regard for practical aspects of the problem. Thus, he chooses to describe the original Kozeny model and theory (Chapter 6.3.2), which has been found to give bad results in practice, and only briefly mentions the Carman modification, without giving the derivation, although it agrees with experimental results more often than not. Again, on theoretical studies in the field of relative permeability, the author quotes Rose (1949), whose assumption of textural constants which do not vary with saturation has been shown to be untenable, in view of the experimental results of Wyllie and Spangler (1952). Rose's equations, such as equation 8.5.2.22, should therefore be rejected in favour of the treatment of Rose and Wyllie (1949), which the author does not describe.

On the whole, the book is likely to form an indispensable part of the library of research workers in this field. As a result, the price in Great Britain is relatively high. During its preparation, two works have been published which are not mentioned in the bibliography: first, the book referred to at the beginning of this notice, the special contribution of which lies in the description of macro surface measurements and in the treatment of molecular flow phenomena during gas flow; secondly, a contribution on porous masses to Volume 2 of "Chemical Engineering Practice" (Butterworths; 1956), which in slightly more than half the pages covers the same field as the book under review but treats the subjects from a chemical engineering angle. PAUL EISENKLAM

BIOPHYSICAL TECHNIQUES

Physical Techniques in Biological Research

Edited by Gerald Oster and Arthur W. Pollister. Vol. 1: Optical Techniques. Pp. xiii+564. 96*s*. 6*d*. (1955). Vol. 2: Physical Chemical Techniques. Pp. xv+502. 91*s*. 6*d*. (1956). Vol. 3: Cells and Tissues. Pp. xv+728. 118*s*. (1956).
(New York: Academic Press, Inc.; London: Academic Books, Ltd.)

THESE volumes contain a large number of articles on the various physical techniques which are applied to biological materials. Such a collection is undoubtedly of value for reference purposes and can be recommended for the reference shelf of nearly all biological laboratories. No doubt much of the information provided could be found elsewhere, but it is often a convenience to have it in one set of volumes which can be consulted rapidly. At the same time there may be some doubt as to the class of reader at which it is aimed. The biologist on the whole will need the help of the physical or physicochemical specialists in operating many of these techniques; while the specialist will want to look at the original papers.

It is inevitable that a compilation of this sort cannot include the latest developments; and these are often the most interesting. One gets the impression that the editors have made a great effort to include all possible physical approaches. This has resulted in space being given to techniques which are of minor importance, which could with advantage have been omitted.

Turning now to the individual articles, we find in Vol. 1 ("Optical Techniques") articles covering spectrophotometry (visible, ultra-violet and infra-red) which are well done. The chapters on the light microscope and interference microscope discuss the theory of these instruments at considerable length. No doubt biologists would profit from a better understanding of these principles, but it may be doubted whether in fact many would make the study of the physical principles which is required. What would perhaps be more useful is a critical evaluation of the different types of instruments. The section on electron microscopy, although it is suitable for anyone who wanted to become acquainted with the principles and requirements of the method, is inadequate for an electron microscopist.

Vol. 2 ("Physical Chemical Techniques") covers an enormous range of methods, from the use of isotopic tracers and ionizing radiations to surface films and electrophoresis. The article by the late Kurt Stern on electrophoresis is a particularly good survey of practical aspects, up to the time of writing. On the other hand, the information given in the article of Spiegler and Wyllie on electrical potential differences really belongs to a text-book of physical chemistry, and it would have been better to make it more practical and more directed at the biological users.

On the whole, much that is given in these volumes will be found in a good text-book of physical chemistry, and I cannot help thinking that the editors have fallen between two stools. They should either have produced a text-book of physics and physical chemistry in its application to biology; or have limited themselves much more closely to what their title implies, that is, techniques. The chapter on magnetic methods by Scott Blois illustrates the difficulties of this kind of compilation. A reader might well look for information on the developing subject of paramagnetic resonance applied to biological materials; but it is dismissed in a very few pages, and he would be forced to look elsewhere to find out what the method involves in practice and also to find the results obtained up to the present.

In Vol. 3 we come to the applications to real biological systems—cells and tissues. This is in the part of the book which fits the title best and which biologists will find most useful. However, the general considerations given above still apply to some extent. J. A. V. BUTLER

COMPUTERS

An Introduction to Automatic Digital Computers

By R. K. Livesley. (Cambridge Engineering Series.) Pp. viii+53+4 plates. (Cambridge: At the University Press, 1957.) 8*s*. 6*d*. net.

IN this book the author attempts to explain to engineers and postgraduate students the way in which a computer works and its application to actual problems. The book is short and the approach unusual in that the author commences with the programming of simple problems and from a discussion of this aspect of computing leads to an account of the way in which a computer works.

The second chapter is devoted to different kinds of input and output mechanisms and storage organs which are in general use at the present time; the third chapter returns to the programming side with a consideration of the methods of constructing programmes for the solution of specific problems; and the work concludes with an examination of the way in which computers are likely to affect engineers in their approach to different problems.

In such a short book it is, of course, impossible for the author to deal to any great extent with real problems, but those examples given are well chosen and form a good basis for a more detailed study of the subject from other books, and the selected bibliography should help in this way.

The author expresses no extreme views. Some of the statements regarding actual problems might perhaps have been improved by more discussion, notable examples being the remarks on automatic programming (p. 38) and on linear programming (p. 46), but the only real fault in the book lies in the omission of an index.

The author's style, the general production and the material are good, and these together with the low price should make it useful to all students of this subject. A. D. BOOTH

THE NEW ELEMENT NOBELIUM*

PREPARATION OF TRANS-URANIUM ELEMENTS

By H. A. C. McKAY

Head of the Heavy Elements Group, Chemistry Division, Atomic Energy Research Establishment, Harwell

NOBELIUM is the tenth new chemical element beyond the old limit at uranium. Uranium is No. 92 in the sequence, nobelium No. 102. Nobelium is exclusively a man-made element: if any ever did exist in Nature, it must all have suffered radioactive decay long ago. Indeed, all the elements beyond uranium—the so-called 'trans-uranium elements'—are virtually exclusively man-made. Traces of the first two, neptunium and plutonium, are produced in Nature by the action of stray neutrons on uranium, but the quantities are trivial in comparison with those produced artificially.

We have three main tools for synthesizing new elements: the particle accelerator, such as the cyclotron or the linear accelerator, which accelerates small charged particles, such as protons, to high energies; the nuclear reactor, which provides an intense source of neutrons; and the hydrogen bomb, which provides an even more intense source of neutrons for a very short period of time.

Before the War we had only one of these tools, the cyclotron. There were also, of course, rather feeble sources of neutrons in the form of radium, or radon–beryllium sources, but their importance was mainly historical. The heaviest particle which could be accelerated in the cyclotron at that time was the alpha-particle. With such resources it was possible to make two steps upwards in the sequence of elements; starting with uranium (the heaviest then known, No. 92), we could produce neptunium, No. 93, and plutonium, No. 94. This was first achieved in 1940, though there had been earlier erroneous claims to have identified trans-uranium elements, before the fission process was understood.

The resources of 1940 could also have produced element No. 95, americium, though it would have required remarkable insight or good fortune to have carried out the right experiments at that time. What happens is that, after alpha-particles have taken us from uranium to plutonium, Nature comes to our aid by providing a negative, or beta-decay, process that carries us one stage farther still. Not every plutonium atom decays in this way—only the plutonium-241 isotope—and the process is slow, so it is hard to detect what is happening unless it is known beforehand what to look for.

In point of fact, the next advance had to await the building of the world's first nuclear reactors. These machines transmuted the elements on an unprecedented scale, so that by 1944 plutonium had ceased to be an extreme rarity and had become available in gram quantities. It could now be used as a new starting-point, and the next two steps upward could be taken. These gave americium and curium—elements 95 and 96.

Five years later, in 1949, this cycle of events was repeated. The continued operation of nuclear reactors had now produced enough americium and curium for use as cyclotron targets, and elements 97 and 98, berkelium and californium, were prepared. It is rather like climbing Everest. Uranium is the base camp, from which one can move up to the next two camps, or with special skill to perceive a route, to one camp higher still. To get any higher

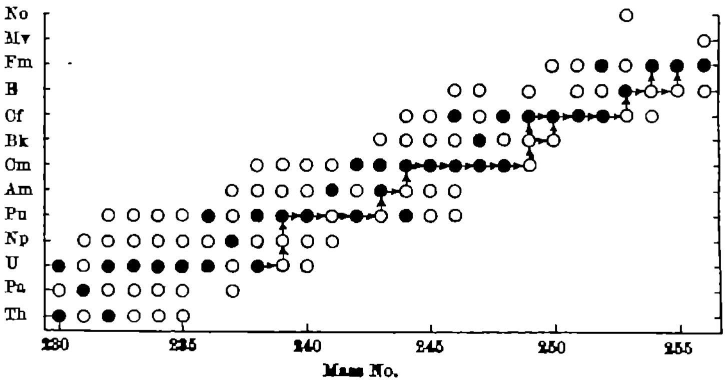

Fig. 1. Sequence of events during the irradiation of uranium with neutrons. Neutron capture processes are represented by a step to the right, and beta-decays by a step upwards

In Figs. 1–4, black circles represent β-stable isotopes; open circles, β-unstable; shaded circles, uncertain

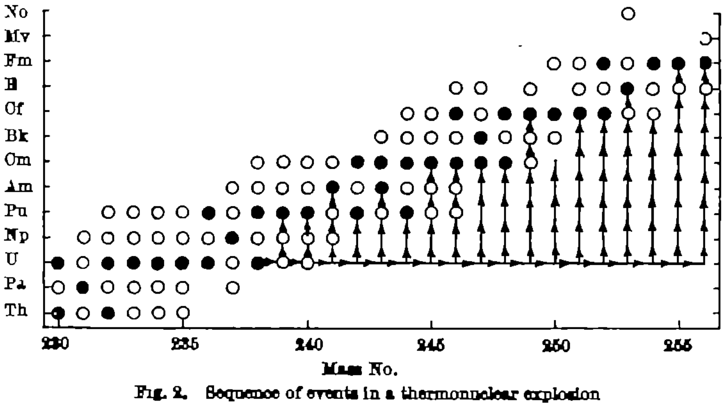

Fig. 2. Sequence of events in a thermonuclear explosion

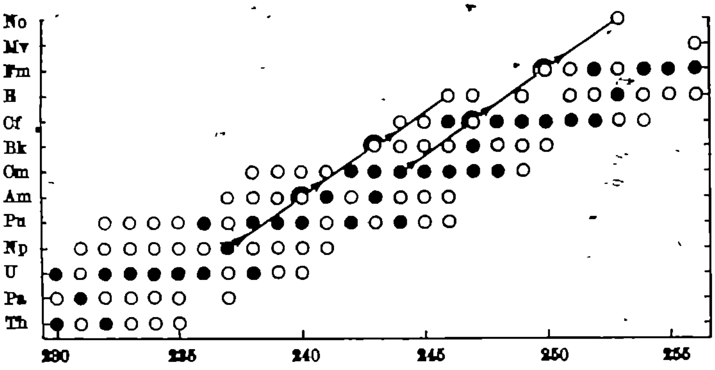

Fig. 3. Examples of heavy-ion bombardment processes

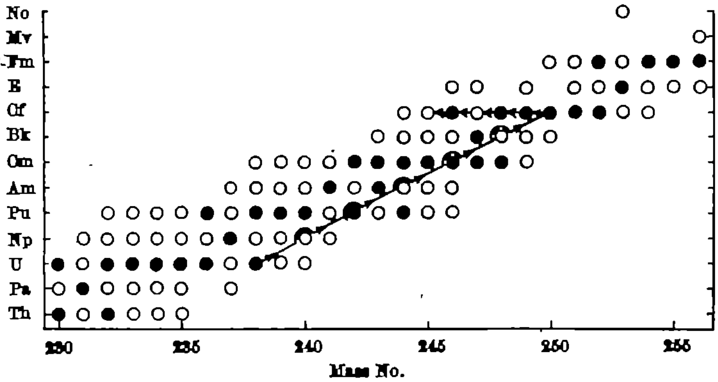

Fig. 4. Stages in a heavy-ion bombardment process

one has to accumulate sufficient supplies at camp II, plutonium. Then one has a further period of build-up before one can progress, and so on; and all the time the atmosphere is getting more and more rarefied. By 1954 the build-up process had gone far enough for the irradiation of californium, No. 98, in a reactor to yield fermium, element No. 100.

Meanwhile, there had been two completely new developments. The first was the explosion of the first hydrogen bomb in 1952. When the debris from the test was analysed it was found to contain both elements 99 and 100, einsteinium and fermium. They had evidently been built up from uranium by a long chain of processes—of successive neutron capture during the very short period of the explosion itself, followed by a more leisurely series of beta-decays. This was a somewhat unexpected result, but it could not be published until 1955 for security reasons.

Meanwhile another new technique was being tried—the acceleration of much heavier particles in the cyclotron. Previously the heaviest particle available was an alpha-particle, and we could only take a two-element step at a time, from, say, curium (No. 96) to californium (No. 98). Now, with carbon ions it was possible to make a jump of six places at a time, with nitrogen ions, seven, and with oxygen ions, eight. Bigger jumps still are likely to become possible in the future, and we can expect great progress when the latest accelerators, designed from the start for heavy ions, come into use.

There was, of course, no security restrictions on publishing the cyclotron work, so it came about that the first announcement of element 99 referred to its production by the bombardment of uranium by nitrogen ions, even though the first discovery was in thermonuclear debris a year earlier. Out of consideration for the true discoverers, the naming of elements 99 and 100 was delayed until the thermonuclear work could be published.

The step to element 101 in 1955 was a brilliant piece of work. In a way it was orthodox—an alpha-particle bombardment of No. 99—but all the techniques had to be pushed to new limits. The latest step, to element 102, will be described by Dr. Milsted.

What are the prospects of further progress? To discuss this question at all adequately we must take a look at the isotope chart as a whole in the heavy region. Uranium-238, the main constituent of natural uranium, is the starting-point for every trans-uranic element. When we irradiate it in a reactor, we get first a single neutron capture leading to uranium-239. This decays by beta-emission first to neptunium-239 and then plutonium-239. This chain is perhaps the most important of all chains of nuclear processes (Fig. 1). But the chain does not stop there. Further irradiation of plutonium-239 gives a very long sequence of products, with neutron capture alternating all the time with beta-decay. With very high irradiations, such as are possible in the world's highest flux reactor, the Materials Testing Reactor (*MTR*) in Idaho, we can get as far as fermium, element 100. In a hydrogen bomb something similar happens. Only this time all the neutron-captures take place first, during the actual explosion, followed by all the beta-decays (Fig. 2).

Heavy-ion bombardment is quite different. It is a matter of a single leap. Fig. 3 shows the leap from uranium to einsteinium under the action of nitrogen ions, and the leap that led to nobelium. The leaps are really rather more complicated than is shown. Take uranium-238 and imagine it being bombarded with carbon-12 ions. First, the two nuclei fuse together to give a compound nucleus, in this case californium-250. But the compound nucleus has a lot of excess energy, and it gets rid of it by boiling off several neutrons, giving lighter californium nuclei (Fig. 4). But one process follows the other so rapidly that we can regard it all as a single leap.

Why can we not push on and on with these different processes, going to higher and higher elements all the time? The reason is that it is like a game of snakes and ladders; by the snakes I mean radioactive decay, which more often than not has the effect of carrying us downwards in the series of elements. The higher we go the more important do the snakes become, and the more difficult it is to dodge them.

Consider again a very high-flux irradiation of plutonium in a reactor. The reactions proceed step by step, with no gaps in the sequence. The members of the chain are all either long-lived, like curium-244 to curium-248, or they are negative beta-emitters, like curium-249, carrying us upwards to the next element. The chain would be broken if it reached a short-lived isotope decaying, for example, by alpha-decay. This begins to happen to an appreciable extent with einsteinium, because einsteinium-253 has a period of only 20 days. Instead of continuing the chain, some of it decays to berkelium-249; and the process of chain-breaking is in full swing at fermium, where fermium-254 and fermium-256 have half-lives of only just over 3 hr. It looks, therefore, as though fermium represents a practical limit to this way of making new elements. Even if we could get past fermium, we should almost certainly fail two elements later.

There is much more hope in heavy-ion bombardments. Here we have a single leap instead of a chain of processes. So there is no need for a lot of intermediate products to be long-lived, as well as the final one. We go to the final product in one process.

The difficulty here, however, is the direction of the leap. It must always be in some such direction as that shown in Figs. 1–4, and unfortunately it takes us away from the most stable region. Broadly speaking, the most stable isotopes form a diagonal band across the chart, and those on either side tend to decay fairly rapidly. Einsteinium-247, for example, has a period of only 7·3 min. It has several possible decay routes, always leading eventually to the stable band, where decay is almost negligibly slow. Given the position of the band, and given the general direction of the leap, we must try to start the leap from as far to the right as possible; that is to say, we want an isotope on the right-hand edge of the band. (If we went beyond the edge we should be again among unstable isotopes, unsuitable for cyclotron targets.) Uranium-238 is quite a good starting material in this respect—the leap carries us across the band, and not very far out the other side.

We can also control the direction of the leap to a small extent by our choice of isotope for the bombarding particles. For example, we can use carbon-13 or even 14 instead of carbon-12. This enables us to finish up one or even two places closer to the stable band. From uranium-238 and carbon-12, for example, we should get a compound nucleus californium-250, and then californium-245 after boiling off five neutrons. But with carbon-13 we should get californium-251 and -246.

Uranium is, of course, rather low down in the chart, so we are limited in what we can do with it. To improve matters we have two expedients. We may increase the size of the leap, which people are trying to do by using heavier bombarding particles, such as neon ions. The difficulty here is that the longer leap takes us farther into the unstable region. The other expedient is to use a heavier starting material. At the moment, the best available is curium-244, from which the transition to nobelium-253 has been made. In a few years, we may hope to have the higher curium isotopes and californium-252.

Nobody knows what will then be achieved, but it certainly seems possible that half-a-dozen new elements will be synthesized beyond nobelium, before radioactive decay, including spontaneous fission, makes further progress impossible.

THE PREPARATION OF NOBELIUM

By Dr. J. MILSTED

Principal Scientific Officer, Heavy Elements Group,
Chemistry Division, Atomic Energy Research Establishment,
Harwell

The work on nobelium to be described was carried out at Stockholm by an international team from the United States, Great Britain and Sweden, because the resources of all three countries were necessary.

The new element was synthesized by the fusion of an atom of the heavy isotope of carbon, carbon-13, with an atom of curium (element 96). In order to obtain the most stable product, it was necessary to use the heaviest available isotope of curium. This is curium-244, and it was only available in the United States as a product of irradiating plutonium with neutrons in the world's highest flux reactor (the Materials Testing Reactor in Idaho). The Argonne National Laboratory near Chicago supplied the curium, and two scientists from the Argonne Laboratory, Dr. Paul Fields and Dr. Arnold Friedmann, took part in the work.

At Harwell we were able to provide the considerable quantities of separated carbon-13 required. We also provided a specially designed ionization chamber for observing the decay of the new element. As curium is highly radioactive, most of the chemical work involved in the preparation of targets and the recovery and purification of curium from used targets was carried out at Harwell. Apart from myself, a chemical technician from Harwell, Mr. A. Beadle, also worked on the problem at Stockholm.

The Nobel Institute of Physics, Stockholm, provided the cyclotron, the only one in the world capable of accelerating carbon ions with the required energy and intensity. The Institute also provided a pulse analyser for observing the energy of the alpha-particles emitted by the new element. The Swedish scientists who worked on the problem were Dr. H. Atterling, Dr. W. Forsling, Dr. L. W. Holm and Dr. B. Astrom. In addition, several technicians at the Argonne Laboratory, at Harwell and at Stockholm assisted in the work.

Due to the hazardous nature of the target material and the difficulty of separating a few atoms of the new element from it, a rather new bombardment technique was employed. This utilized the recoil or 'knock-on' effect. A thin layer of curium was deposited on an aluminium foil, and the product atoms knocked out of the target were collected in a plastic film after passing through a very thin aluminium cover foil placed over the curium target, to prevent the spread of curium contamination. The plastic film was ignited on a platinum disk to recover the product atoms. The decay of these atoms could be observed directly, or they could be dissolved off the plate for chemical identification.

A new alpha-activity of 8·5 MeV. energy was observed among the products, and although only seventeen events of this energy were observed with certainty, it was possible to show that the new alpha-emitter had the expected chemical properties for an isotope of element 102. The chemical experiments in each case used ion-exchange techniques. When the activity was absorbed on a column of cation-exchange resin and washed off with a complexing agent (alpha-hydroxy *iso*butyric acid), the

8·5 MeV. alpha-activity appeared in the drops predicted for element 102.

There was a possibility that the activity might be due to thorium-225, which has a half-life of 8 min. and produces a short-lived daughter, polonium-213, which emits 8·4 MeV. alpha-particles. This was eliminated, by eluting the activity from a cation-exchange column with 6 *N* hydrochloric acid. Under these conditions, thorium is retained by the column, while the trivalent actinide elements are eluted rapidly. The 8·5-MeV. alpha-activity was found in the actinide fraction.

A graph showing the moment of decay of each of the seventeen atoms observed gave a half-life of about 10 min. for the new activity. The observed alpha-particle energy and half-life, the absence of spontaneous fission, and the method of preparation lead us to believe that the mass number of the isotope prepared is either 251 or 253, the latter number being more likely.

We have suggested the name 'nobelium' for the new element, in honour of the Institute where the work was carried out and also in recognition of Alfred Nobel's encouragement of world science and international understanding. The symbol will be No. This is the first of the trans-uranium elements to be discovered on European soil, and the first to be found by an international effort.

TRADES UNIONS, SCIENTIFIC DEVELOPMENT AND HUMAN RELATIONS*

By LEWIS T. WRIGHT

General Secretary, Amalgamated Weavers' Association, and Chairman of the T.U.C. Scientific Advisory Committee

PROF. K. BOULDING, in "Goals of Economic Life", has said that we have learned in our time that the increase of productivity is a precondition to the abolition of poverty. To-day we accept this principle without question, but in the search for new methods of increasing productivity we find ourselves faced with new problems and related difficulties, from which we have tended to shy away. We have discovered, or rather re-discovered, that the social implications of rapidly increasing productivity, generally expressed to-day in the word 'automation', can become the bottleneck of production, and that unless these social problems are solved in parallel with our technical problems progress will be seriously retarded.

The physicist, the pure scientist, and the technologist have outrun the social scientist in the race for knowledge and 'know-how', and the left hand of knowledge has not known what the right hand has been doing. As Prof. Emerson puts it, "There is too little social science that diagnoses social disease and discovers cures". But these social problems are being forced upon our notice, and the social scientist has quite as important a part to play in helping to achieve an age of plenty as have inventors of the automated factory. The trouble is that there are too few social research workers to cope with the rapidly developing technological changes, and it is very encouraging to know that the Department of Scientific and Industrial Research has recognized the importance of work in this field, and will develop its work in the study of human relations.

People are rather confused as to what are the real implications of the automation age. It is seen by some as a grand cornucopia from which flows a never-ending stream of all the material things of life—a press-button paradise. Others see it as a juggernaut pressing the masses down ; a thinking machine eventually conquering the unthinking masses. Neither can be true, but it would be unwise to leave it at that, for there are dangers—social, moral and economic—which need to be examined, indeed, which first need to be discovered. It is the job of the social scientist to discover the evidence, to sift it and to show us how human dignity need not suffer to gain material prosperity.

If this, then, is such a formidable task upon which the social scientists have scarcely yet started, how much more formidable is the task of those who are faced now with the problem of trying to understand workers' reaction in their own plant in the face of change ? We need a little more food, and we are looking to the social scientist to produce it for us.

First let me say that the British trades union movement generally accepts the principle that only by increased productivity can higher standards of living be won. I know of no trades union in Great Britain which opposes the principle of automation, but none will approve the development of the machine at the expense of human dignity. This is where the conflict may arise.

The trades union movement recognizes that it has a responsibility to foster productivity, whether it be through the introduction of automated processes or by modern methods of work study. It cannot, nor does it, abdicate its responsibility. To demand, as the Trades Union Congress does, the right to be consulted by the Government of the day on all major factors affecting the economy of our country carries with it the responsibility that goes with such consultation. Last year more than a thousand delegates to the T.U.C. declared their belief that automation can materially improve their standard of living. This does not mean a declaration that they will be prepared to pay any price to get it. The development of the new technique will depend very much upon the price that workers may be asked to pay.

It is true that we want more and more of the material things of life ; but many workers are coming to the conclusion that one of the best 'buys' in this modern world is leisure—and that in itself creates serious problems. They are thinking of Continental holidays, for example, with the time necessary to enjoy them. This is no bad thing, and trades unionists believe that automation and concomitant industrial developments could lead not only to higher real wages, but also to a shorter working week. In other words that automation may enable them to buy not only television, refrigerators and motor-cars, but also more leisure. But we do not believe that the benefits of automation will come automatically to the workers. They will, in a competitive and acquisitive society, have to be fought for. The theory that prosperity is something for which we must work hard now in the hope that some of it will eventually trickle down to the workers does not commend itself to the trades unionist. He wants to be reasonably sure that it is going to mean something to him at the same time as it means something to everybody else.

---

* Substance of an address delivered to the Institute of Personnel Management at its National Conference in Harrogate during October 4–6.

It is clearly seen, of course, that while the advent of automation will bring problems and difficulties it would be worse if, as a result of insufficient automation, standards of life were reduced because of failure to keep up with the rest of the world in the exploitation of these new developments. It is seen that so long as it is the machine which is exploited and not the worker developments could proceed apace, and increased prosperity come to all. Workers have made up their minds that it must come in this way, and are not prepared to play the part of Lazarus to some automated Dives.

None can say that workers have no reason to fear automation. Since the Industrial Revolution up to recent years, the exploitation of scientific developments in industry has proceeded with a complete lack of consideration for the human being. Human factors have been recognized and ignored. The human factor has been seen as an impediment to progress; an obstacle that somehow or other must be removed. When it could be swept away from the path of industrial progress this has been done. Progress had become a dichotomy. It will be remembered how, in the interests of rationalization and progress, the town of Jarrow was closed down. This rationalization, this progress, meant many thousands of people becoming suddenly unemployed. Acute misery for thousands of families followed. Hunger marches and bitterness ensued—an odd sort of progress indeed. There are to-day millions of working class folk who remember those days, and when the word 'rationalization' or 'automation' is used a cold fear clutches their hearts.

We know that much greater attention is given to-day to the problems of distressed areas and of employment generally. The retraining of workers and transfers from one job to another are becoming more common. Industrial undertakings think twice before closing a factory in the interests of rationalization. Full employment, too, means that in most cases displaced workers can find alternative employment. Despite these trends, many workers think of technical progress as synonymous with unemployment. It is the experience of thousands of workers that technical progress has resulted in the loss of jobs. We are inclined airily to dismiss this line of thought by saying: "In a period of full employment there are jobs for all", as if that settles the issue. Sometimes we say that the workers are wrong in harbouring such fears—and think no more about it.

Our negative reasoning is no better than the negative reasoning of the worker. We must recognize that he does think in certain ways, whether rightly or wrongly, and it is to the interests of industry that we try to understand why he thinks as he does, and to take action to demonstrate that his fears are unfounded. Workers must be shown that industry has as much concern for them as for the machines.

It is the easiest thing in the world to prepare a carefully reasoned statement to prove that a cheaper product stimulates demand and in the long run makes for more jobs. Few workers are interested in the 'long run'. I think it was Keynes who said that we live and die in the short term. Workers live on weekly wages, and in this age of hire-purchase payments, stimulated by advertisements, they budget their income, of which by far the greater proportion goes out in some form of weekly payment. A week or two of unemployment plays havoc with their domestic economy. A month or so of unemployment can break them. Little wonder that the theory of marginal unemployment being an inevitable precondition to bigger and better jobs in the future does not appeal. Their fears have been heightened by stories of 'push-button' factories and electronic brains, and they see not only unemployment facing them but also something nearly as bad, particularly to the older age group—the changing of their job. It is true that full employment cannot mean keeping the same job at the same place. There may be the same job at a different place, or a different job at the same place. Changing skills are inevitable; but so is rain and the sun, and we take steps to protect ourselves from the worst effects of both. To say that there is an alternative job for a man who has spent thirty years in following particular skills may be a rational approach and coldly objective, but from the subjective point of view of the displaced man it is rather a haphazard conclusion, particularly if wages for the new job are lower.

What I am saying is not intended to justify the reasoning of workers, but to recognize that the subjective thinking of workers is based upon experience, and their subjective approach is as logical as the objective thinking of those who can view the 'long term' with a reasonably easy mind.

It would appear that one of our main tasks is to try to reconcile the subjective and the objective approaches to the changes which scientific progress will bring.

What can employers do? With the development of technocracy over the years the word 'employer' has lost much of its meaning. Years ago employers were recognized as persons. Very often they were the owners of businesses, known personally to their workers. To-day the word 'employer' is not personalized, and few workers know who their employers really are. Any loyalty they may have is to something abstract and impersonal. This phenomenon makes it most important that a clear line of adequate communications should flow from top management down to the workers on the shop floor, and equally important from the shop floor up to top management. Lack of adequate communications is probably, as Elton Mayo said many years ago, "the outstanding defect that civilization is facing to-day". The ability of an individual or a group to pass on ideas and feelings to other individuals or groups in a clear and readily understandable way is not given to all. But without this capacity no co-ordinated and co-operative effort is possible. This means in the first place that those who have to do with the leading and directing of labour must be chosen by top management with the same care that they put to the choice of new equipment and lay-out planning. To make a mistake in the choice of one can be as serious to the undertaking as a mistaken choice in the other, because it will not do much good to consider carefully the choice of new equipment if you are not likely to get co-operation in its working. As the amount of fixed capital grows, the incidence of labour costs to overheads diminishes, but the importance of labour relations increases, particularly in a period of full employment.

I know of one textile undertaking which has installed ninety-six of the latest type Sulzer looms, each loom costing £3,500. The total capital cost of building, air-conditioning plant, looms and so on was £800,000. The mill works three shifts and employs twelve weavers—four per shift. The wages of the twelve weavers, covering the three shifts at £14 per weaver a shift, are £168 per week. The overheads on capital investment alone, taking 5 per cent interest on capital and 5 per cent amortization, with 250 working days per year, are £325 a day. One weaver off work for a day becomes a very serious matter. For the mill to be stopped for a week will cost the firm employing only twelve weavers at least £2,000 when considering loss of profit and so on. It is true that the problems of industrial relations ought to be solved far more easily with such a small labour force, but the dangers of ignoring these human considerations are shown up the more clearly in cases of a low ratio of labour costs to that of high fixed capital.

If we allow knowledge of scientific and technological progress to outstrip knowledge of human behaviour we are creating for ourselves a bottleneck to productivity. Worker attitude, habit and thoughts are the product of the experience of his kind. Traditions are followed, born of this experience, and if we believe them to be wrong we have clearly to demonstrate in a practical fashion that they can now safely be abandoned. Sound communications can do much to change outlook. Information must be conveyed so that it can be readily understood and readily accepted, and reasons why there should be a change or an experiment should be put clearly enough for it to be accepted. We all know about the Hawthorne experiment, where girls were asked to co-operate in new methods of work. Stuart Chase attributed the remarkable results of the Hawthorne experiment to several factors, the most important being that in asking for the help and co-operation of the girls a change of attitude had been effected. They felt they 'belonged'. They were an important part of an experiment, and had been treated as such. They felt they were no longer just 'human machines'. They had not been ignored. They had been shown the whole picture. Human nature has not changed much since the Hawthorne experiment, and we ought by now to have learned that if workers are treated as human machines or automatons they will behave as such; but if they are treated as intelligent human beings they are the more likely to respond as such.

Attention should be directed to the axiom that people cannot be taught who feel at the same time they are being attacked. Most workers work on the basis that management is guilty until it is proved innocent, and there is a good deal of work to do in this field.

Most of what I have had to say on communications applies to those who are in daily contact with the workers, although top management must set the pace. The problem of redundancy is largely a matter of policy, decided at the very top. It is as necessary for top management to take long-term views in relation to the workers as it is for the workers to take a long-term view in relation to the machines. If workers are to continue to be exhorted to be realists in the problem of productivity, management must be realist in relation to continuing employment and standards of living. They should begin planning against the problems of redundancy at the same time that they begin planning the introduction of new machines. They should be prepared to consult and negotiate, for the workers will feel that as all decisions by management have their impact upon them, particularly in the field of automation, they should be consulted. The wise employer will recognize that joint consultation, effective consultation, is essential if the new plant is to run smoothly. There is plenty of room for improvement in joint consultative concepts and procedure.

So far I have discussed relationships between employers and workers. The Government, too, has a part to play in these exercises. In my opinion, to imagine that the lash of unemployment will assist scientific and technical development is a mistaken view. It could serve only to breed another generation of Luddites. Full employment creates a climate most suitable for the acceptance of change, and it is for Governments to follow policies making for full employment and to allow automation to develop smoothly. They must encourage and sponsor more research, not only in the scientific and technical field, but also in the study of human relations. This, I am glad to say, they are doing through the Department of Scientific and Industrial Research.

The trades unions, too, have an important part to play in this era of change. The trades unions have never been opposed to change. Indeed, they exist to create change—change in the form of higher wages, shorter hours, more holidays; but they want change for the better, not for the worse.

I have already said that the T.U.C. has accepted its obligations in regard to the development of automation, and there exists an appreciation of the fact that our Welfare State can survive only on the basis of continuing and increasing productivity. It is part of our task to educate our members to understand this point of view, and to secure their co-operation in raising the efficiency of industry. The trades unions are doing a good deal in this respect, and are trying to put over the new concepts and the new needs of our age. But I would again point out that "You cannot teach people who at the same time believe they are being attacked". The trades unions can and will play their part, but the main job will be done in the board room and down the line of management. If trade unionists believe they are being attacked, only management can disabuse their minds. The trades unions cannot successfully do that. They can only help. We recognize that greater dangers can arise through automation proceeding too slowly in the United Kingdom while developing more rapidly in the rest of the industrial world. But human values cannot be subordinated to technical efficiency. As a trade union leader I feel it as much my responsibility to bring home this truth to industry as it is to bring economic truths to the attention of my members. The machine is for man, not man for the machine.

BEHAVIOUR AND FATE OF LYMPHOCYTES

LYMPHOCYTES make up a substantial proportion of the leucocytes in mammalian blood. Lymphocytes are not, however, confined to the blood: they are present diffusely throughout the submucosa of the intestine and in the bone marrow; they are the predominant cell-type in the normal lymph node, in the Peyer's patches of the intestine and in the lymphoid tissue in the lung and in the spleen. In pathological material they are particularly associated with areas of chronic inflammation and with certain tumours. Despite this widespread distribution in both normal and abnormal tissues, very little is known about the life-history of the lymphocyte and virtually nothing about its function. The problem is made more striking by the apparently high rate of replacement of the blood lymphocytes; in the rat, for example, the output of lymphocytes from the main lymphatic vessels is sufficient to replace all the lymphocytes in the blood at least eleven times daily. So far as the fundamental properties of lymphocytes are concerned, there would only be agreement that they are motile, non-phagocytic cells which do not respond chemotactically to any stimulus yet tried.

Lymphocytes are produced in the lymph nodes. These are complex structures containing several apparently distinct cell-types: the phagocytic cells lining the lymph channels enable the lymph nodes to filter foreign material from the fluid percolating through them; there is very good evidence that plasma cells are responsible for the production of circulating antibodies; but there is, as yet, no function of lymphoid tissue that can be definitely attributed to its content of lymphocytes.

The problem of the behaviour and fate of lymphocytes was discussed at a Ciba Foundation Study Group held in London on July 23 under the chairmanship of Prof. P. B. Medawar.

The appearance of living human lymphocytes *in vitro* was well illustrated in a film by R. J. F. Pulvertaft (London). The cells were examined in a narrow layer of culture fluid enclosed between a glass cover-slip and an agar surface. Time-lapse cinematography showed that lymphocytes often moved towards, and adhered to, malignant cells, to megakaryocytes and to cells of all kinds in mitosis. Having adhered to these cells, the lymphocytes often moved continuously around their periphery, a phenomenon for which the term 'emperipolesis' has been coined. The discussion of this paper centred mainly on whether or not emperipolesis might be an artefact due to the special conditions existing in the agar–cover-slip chamber. G. M. Watson (Harwell) showed that lymphocytes in such preparations will gyrate around glass beads; he suggested that when large cells or glass beads are compressed into the agar by the cover-slip a circular trough is formed around them in which lymphocytes can become trapped. The lymphocytes cannot escape from this trough because, unlike other leucocytes, they will not adhere to glass surfaces; they therefore continue to circle around in it.

The part played by the thymus in the production of lymphocytes was discussed by E. Andreasen (Copenhagen). The high turnover of deoxyribonucleic acid phosphorus and the high mitotic activity in the thymus suggested that it was an important source of the lymphocytes in the lymph and the blood. However, the measurement of the concentration of lymphocytes in the blood and the lymph of thymectomized rats led to the conclusion that very few thymus-lymphocytes leave the organ, and that the production of new cells in it is more or less balanced by a continuous destruction of lymphocytes by the reticulum cells. It was pointed out that the concurrent new formation and disintegration of lymphocytes appears to be a widespread phenomenon in lymphoid tissue. O. A. Trowell (Harwell) described the occurrence of such a process in rat lymph nodes cultured *in vitro*. The histological appearance of these cultures suggested that the reticulum cells were able to phagocytose the remains of dead lymphocytes and then to differentiate into large lymphocytes. The transformation of small lymphocytes into macrophages was also thought to occur, and it was suggested that the small lymphocytes might constitute, in the animal, a reserve of potential macrophages. The discussion showed that the possibility of lymphocytes transforming into other cell-types remains a highly controversial topic.

The transplantation of myeloid and lymphoid tissue was discussed by J. F. Loutit (Harwell) and N. A. Mitchison (Edinburgh). Following a lethal dose (LD_{99}) of X-rays, mice can be induced to recover by an intravenous injection of myeloid cells. Recovery is due to the recolonization of the damaged myeloid and lymphoid tissue by the cells of the donor. When these cells are derived from the same inbred strain, the recolonized animals live nearly as long as normal mice. But when the transplanted cells come from another strain of mice, or from the rat, many animals die 1–3 months later. It was argued that this secondary death was the result of an immunological reaction against the antigens of the host by the transplanted cells. In non-irradiated hosts, transplanted lymphoid cells also become localized in lymphoid tissue. They are capable of immunological activity, for they continue to produce antibody when taken from donors which have been actively immunized. Unless taken from the same inbred strain as their host, the transplanted cells are soon eliminated by the homograft reaction.

L. D. Hamilton (New York) and J. Ottesen (Copenhagen) described the incorporation of radioactive isotopes into the nucleic acids of lymphocytes in the blood. Hamilton administered ^{14}C-adenine to patients with chronic lymphatic leukæmia and isolated the purines from the deoxyribonucleic acid and the ribonucleic acid of the circulating leukæmic lymphocytes. The radioactivity of the purines in both the ribonucleic acid and the deoxyribonucleic acid declined in two phases, rapidly at first, and then slowly, with a very prolonged retention of radioactivity. An analysis of these curves suggested that there were two populations of lymphocytes, one with an average life-span of eighty-five days, and the other with a half-life of about three hundred days. A great deal of interest centred around Hamilton's suggestion that the prolonged retention of radioactivity in the lymphocytes might not indicate cells with a very long life-span but might be due to a continuous re-utilization of large fragments of nucleic acid or nucleoprotein during the formation of new lymphocytes. The biochemical evidence did not enable a choice to be made between these alternatives, but Trowell suggested that the presence of cell debris in the reticulum cells in lymph nodes could provide cytological support for the idea of re-utilization.

Ottesen described the incorporation of phosphorus-32 into the deoxyribonucleic acid of lymphocytes in the blood of normal human subjects. An analysis of the specific activity curves again suggested the existence of two populations of cells but with shorter life-spans than those calculated by Hamilton for leukæmic lymphocytes: about 20 per cent had a mean age of 2–3 days and 80 per cent a mean age of 100–200 days. There was evidence, both in man and in animals, that lymphocytes may remain in lymph nodes for a considerable time after their formation. Thus, autoradiographs of mouse lymph nodes showed that some lymphocytes labelled with carbon-14 were present in the nodes more than two months after the administration of the isotope.

These experiments with radioactive labels suggested that the life-span of at least some lymphocytes may be considerably longer than was at one time supposed. There was, however, some prejudice against the idea that lymphocytes can live for as long as a year, and, in discussion, this appeared to be a reason for inclining towards the hypothesis of re-utilization.

The problem of the rapid turnover of the lymphocytes in the blood was discussed by J. L. Gowans (Oxford). An apparatus was described for the continuous intravenous infusion of lymph and lymphocytes into unanæsthetized rats with thoracic duct fistulæ. It was shown that there is a direct relationship between the number of lymphocytes entering the blood and the number emerging from the thoracic duct. Thus, the fall in the cell output that occurred on the prolonged drainage of lymph from the thoracic duct could be prevented by the intravenous replacement of all the lymph and cells collected from the fistula. Similarly, after prolonged drainage of lymph, the low output of cells from the thoracic duct could be restored to normal by the transfusion of lymphocytes from other rats of the same inbred strain. A vigorous transfusion of lymphocytes almost doubled the normal cell output of a freshly cannulated rat. The number of lymphocytes transfused could be roughly accounted for by the extra lymphocytes appearing in the thoracic duct lymph of the recipient rat. These effects were most probably mediated by living lymphocytes since the administration of cell-free lymph or of lymphocytes killed by a variety of means had no effect on the cell output. It was felt that the results could not be accounted for by a burst of new cell formation initiated by the transfused cells; they strongly suggested that the apparently high turnover of the lymphocytes in the blood of the intact animal is due to a continuous recirculation of lymphocytes from blood to lymph to blood. This idea was further strengthened by an experiment in which the transfusion of radioactively labelled lymphocytes resulted in their rapid appearance in the thoracic duct lymph.

J. M. Yoffey (Bristol) said that lymphocytes probably recirculated on a small scale via the afferent (peripheral) lymphatics, but that there were a number of difficulties in accepting the hypothesis that recirculation occurred on the scale envisaged by Gowans. Detailed histological observations on the regenerating bone marrow of irradiated guinea pigs tends to suggest that lymphocytes provide a reservoir of stem cells which contribute to the regeneration of marrow.

In the experiments described at the meeting and in discussion it was again made plain that there is, as yet, no real clue to the physiological function of the lymphocyte. Prof. Medawar, in his concluding remarks, expressed the appreciation of those present for the hospitality given by the Ciba Foundation.

ELECTROLYTE PHYSIOLOGY

At the British Association meeting in Dublin, the session held by Section I (Physiology and Biochemistry) on September 9, on "Electrolyte Physiology", opened with a paper by Prof. E. J. Conway (University College, Dublin) on "Energy and Form in the Living Cell". In a paper on so wide a subject, the treatment was necessarily limited to certain aspects, but it includes some basic considerations of ionic permeability of the animal-cell membrane.

The energy requirements of the living cell could be listed under the following general headings: (*a*) maintenance of size and composition; (*b*) special functions such as contraction, conduction and secretion; and (*c*) cell growth and division. The treatment was limited to the first heading, the fully developed cell being considered in general, apart from special functions.

Energy required for maintenance of size with respect to water-content. It is reasonable to suppose that the primitive cell was surrounded by a membrane, necessary to retain substances required for its activities. This membrane is considered to be freely distensible, the comparatively rigid plant-cell membrane developing later as an adaptation to sites with variable mixing of sea and fresh water.

As the membrane may be assumed to exist primarily for conserving essential cell substances, it should have some limiting permeability. If it were quite impermeable to solutes, necessary material would be excluded, without some special expenditure of energy. Passing from such permeability to one in which sodium and potassium ions as well as small anions could enter with equal facility per unit concentration, then, from considerations of osmotic, electrical and Donnan equilibria, the following equation can be written[1] for the equilibrium condition

$$\eta = C - (\varepsilon^2 + 4\Sigma bd)^{1/2}$$

Here η represents moles of non-diffusible material within the cell (using the term non-diffusible with reference to the membrane), ε is the arithmetical sum of the electrical charges thereon (expressed as m.equiv.), and b and d are external concentrations of a diffusible cation and anion. Assuming the external conditions to resemble that of the internal medium of higher animals, then the value for η or for the essential substances within the cell would be very small, approaching zero, even with zero ϵ value. But if the permeability were reduced so that while the hydrated potassium ions were allowed to pass the larger hydrated sodium ions were excluded, then with the same conditions the η value would be considerable, even with ϵ about the same as η. It is to be noted that with such an arrangement there would be high internal concentration of potassium ions and a low or vanishing concentration of sodium ions, and such a relation would continue to exist without any energy being specially directed thereto.

However, it may be supposed that a membrane allowing potassium ions to pass freely will not indefinitely exclude sodium ions, and these will enter slowly along with chloride ions, the cell swelling indefinitely. It would appear necessary, then, for the cell to possess some mechanism to counteract this process, either by the active excretion of water, or of chloride ions, or of sodium ions.

What in fact has occurred is that the cell became endowed with the property of excreting sodium ions, the mechanism being referred to as the sodium pump. As the sodium pump operates in the yeast cell as well as in muscle and nerve fibres of higher organisms, it may be assumed to be a general cellular endowment proceeding from the earliest development of the cell in a marine environment.

Position with respect to plant cells. The argument based on a ready distensibility of the cell membrane does not apply to the comparatively rigid membrane of the plant cell. However, the following considerations may be advanced: (*a*) the kind of cell permeability once established in association with the sodium pump in a fully marine environment and presumably over hundreds of millions of years was retained by plant cells as a fixed endowment; (*b*) the long conditioning to relatively high concentrations of potassium within the cell may have had a secondary effect on enzyme activity; (*c*) the long adaptation to the high concentration of potassium may have required—dependent on the conditions—the active transport of potassium into the cell.

Energy required for maintenance of organic composition. It would appear that the organic and essential non-diffusible constituents of the cell are labile and constantly breaking down, and are then necessarily being rebuilt when the cell is in its resting form or respiring condition.

This continuous process of decay and necessary renewal may well constitute a major fraction of the requirement of resting energy, in unicellular organisms or in the tissue cells of poikilothermal organisms. At the same time, in the unicellular organism, it must be taken into account that surplus metabolism is required for growth and cell division, this being essential for the survival of the species.

In certain cell states, as in spores and seeds, associated with a comparatively high degree of desiccation, the breakdown process may be indefinitely suspended, and there are authenticated instances of seeds germinating in suitable environments after lying dormant for centuries.

From a quantitative point of view the non-diffusible and labile components of the cell in general consist very largely of protein and various phosphate esters, much the greater fraction being protein. Here the principle may be entertained that no non-diffusible constituent of the cell is present without functional significance, which would imply that if all the functional non-diffusible material were removed from the cell, nothing is left, except water and salts. But what functional significance is to be attached to cellular protein, ignoring the specialized function of certain fibres? The answer that naturally arises is that, in general, the total protein of the cell is nothing more than the sum of its enzymes; an answer that must have occurred to many workers independently.

Cellular size levels and energy exchanges. Here it is initially helpful if only in a tentative way to consider the advantages and disadvantages that may arise from a diminution of cellular size proceeding from a given level. The following advantages may be mentioned: diffusion of substances necessary for metabolism throughout the cell becomes more rapid; interaction of rapidly acting respiratory redox systems is facilitated; and the entrance of necessary material and excretion of waste products are promoted. At the same time disadvantages of the following kind arise: other things being equal, the rate of entrance of sodium into the cell is increased and so is the work for the sodium pump; while below a certain critical size it may be supposed that each single cell can no longer have the totality of enzymes necessary for its full metabolic life.

Considering the more important aspects of these, it may be noted that, for the functioning of the rapidly acting respiratory enzymes, it would seem that the smaller the cell the better, down even to bacterial size; but for minimizing the work of the sodium pump, and what is probably more important, for achieving the necessary complement of enzyme molecules, a certain critical size, greater than that of bacteria, may be expected.

What in fact happens is of great interest in the light of such considerations. The respiratory enzymes inside the cell are almost entirely incorporated in bacteria-like particles termed mitochondria, and are surrounded by a more extensive cytoplasm. Thus the maximum advantage would appear to be obtained, but not by the apparently obvious device of a critical size governed by a balance of advantages with disadvantages.

Cellular size relative to total energy exchanges. This can be well examined by comparing the sizes of cells of the same tissue-type throughout the great range of adult body-weight in the mammalia. Years ago, I assembled data[1] from the literature relative to the size of the nephron cells and other associated data for several species with a total range in body-weight of a factor of 20,000 (mouse to horse or cow). The surprising fact emerged that the size of the nephron cells was quite independent of the body-weight, but it could be shown that the total effective work done by the single cell is approximately the same. An interesting series of relations was established, and which within the sampling error could be written

$$V = \alpha \times W^{0\cdot 666} \qquad g = \delta \times W^{0\cdot 111}$$
$$n = \beta \times W^{0\cdot 444} \qquad d = \epsilon \times W^{0\cdot 000}$$
$$l = \gamma \times W^{0\cdot 222}$$

where W is the body-weight, V the average volume of urine, n the number of glomeruli, l the length of the first convoluted tubule, g the diameter of the glomerulus and d the diameter of the cell, with α, β, γ, δ and ϵ constant relative to W. An explanation of these relations was then essayed, which with some modifications would still appear valid.

I also included a brief account of free-energy exchanges within the cell, including the formation and significance of energy-rich phosphate bonds and the thermodynamic theory of the redox pump, which has been incorrectly treated in some recent publications.

Mitochondria and ion transport. The question of ion transport in mitochondria was taken up by Dr. M. G. Harrington (University College, Dublin). The name mitochondria, signifying 'thread' and 'granule', was given by Benda[3], who observed them as filaments or as small rods or granules both in the living cell and in fixed sections.

Mitochondria in the living cell appear to be in a state of constant movement, either a wriggling motion or a transposition from one part of the cell to another, and from the nucleus, for example to the cell membrane and back again[4].

In the isolation of mitochondria from homogenized tissue it is important to observe certain conventional conditions for their separation by centrifugation[4]. Bensley and Hoerr[5] and Claude[6] were the first to stress this point, which was developed very fully by de Duve and Berthet[7]. Concerning the functions of mitochondria there were some early pointers strongly suggesting their connexion with cellular respiration, and at present it would appear from the work of Schneider and Hoogeboom[8] that they are the site of the electron-transporting system and in particular of cytochrome oxidase. From the work of Green[9], Harman[10], de Duve and Berthet[7] and others it appears that they are also the site of oxidative phosphorylation and the enzymes of the Krebs cycle.

While the major significance of mitochondrial study lies with the location of enzymes within the cell, their linkage with respiration and their movements have induced several workers to examine their possible role in active transport.

The kind of active transport contemplated for animal-tissue cells is that of the sodium ion, since for muscle, gland and nerve the evidence is very strong that the fluxes of potassium are of a passive kind. Apart from questions of active transport it is also of importance to ascertain exactly how much potassium and sodium are associated with the mitochondria.

An essential prerequisite to any such study would be the determination of the extraparticulate fluid volume. Theoretically this could be expected to have a maximum value of 26 per cent, corresponding to the value for rigid spheres[11]. Using inulin, data in the literature show values as high as 66 per cent[12], which apparently can be interpreted only on the basis of an entrance of the inulin into the intramitochondrial water, presumably in varying amounts depending on the experimental conditions. In this department, inulin, sucrose and thiocyanate were used to study the extraparticulate volume, all three methods giving extremely high values. A closer study of the permeability of the mitochondria to thiocyanate yielded anomalous results which were therefore disregarded. When the mitochondria were rendered sucrose-free, by washing with saline prior to the estimations, serial values were simultaneously obtained, the thiocyanate value being of the order of 70 per cent, that for sucrose 50 per cent while that for inulin was only 20 per cent. These figures may well point to a compartmented structure for mitochondria as visualized by Werkheiser and Bartley[13], and as might be expected from the many electron micrographs of mitochondria clearly showing the existence of internal membranous structures. The significance of the effect of washing in saline is not clear, but it may point to the need for further experiments using solutions closely approximating to cell-fluid itself as the ideal preparative medium for the isolation of the mitochondria.

Hormonal control of electrolyte metabolism. Finally, Dr. D. Hingerty read a paper on the control of electrolyte metabolism by hormones. The secretion of the posterior lobe of the pituitary and that of the adrenal cortex appear to exert a direct control over water and electrolyte exchanges in the body. In recent years much new information on the functioning of these glands has been obtained. The active principles of the posterior lobe have been isolated and their structure established[14]. They are two octapeptides, which have now been synthesized, and are closely related structurally. One is responsible for the antidiuretic and pressor activities, whereas the other has oxytocic functions.

Originating in the hypothalamus, these factors are stored in the posterior lobe and liberated as required in response to changes in plasma volume, electrolyte concentrations in plasma and other stimuli.

The processes whereby the adrenocortical principles are synthesized and released into the circulation have now been deduced in some detail, the final products (mainly corticosterone and 17-hydroxycorticosterone) being produced after condensation of 2-carbon fragments into squalene and cholesterol, successive alterations of the cholesterol molecule being brought about by enzymes located in various components of the adrenocortical cells[15]. These reactions are greatly accelerated by adrenocorticotrophic hormone, but the mode of action is obscure.

In recent years much work has been done on the isolation and investigation of aldosterone[16], a remarkably potent hormone with respect to electrolyte exchanges. It has some unique properties in structure and mode of secretion, its release into the circulation being determined more by levels of circulating electrolytes[17] (especially potassium) than by adrenocorticotrophic hormone.

The antidiuretic and adrenocortical hormones would appear to act (with respect to water and electrolyte exchanges) mainly on the kidney tubule, but a more general action on sodium and potassium exchanges exists as judged from effects on the isolated frog skin[18] and even on fermenting yeast cells[19].

If, in the mammalian nephron, the most prominent action of the adrenocortical hormones is an inhibition of potassium absorption (as happens in fermenting yeast) then, after adrenalectomy, more potassium would be absorbed with a rise in the content of potassium in the plasma. The hypothesis may then be entertained that the increased uptake of potassium ions has an inhibiting effect on the re-absorption of sodium ions, by displacing sodium from the carrier complex. As a result the plasma sodium would tend to fall. With a high concentration of sodium down the nephron lumen such effects may be expected to be minimized. In this way some of the major facts on the inorganic electrolyte distribution of adrenal insufficiency and high intake of sodium may be interpreted[20].

With regard to the rather arbitrary division of the cortical hormones into 'mineralocorticoids' and 'glucocorticoids', it is to be noted that even the very potent 'mineralocorticoid' aldosterone has considerable 'glucocorticoid' activity, the difference between the two groups of hormones being quantitative rather than qualitative. The changes in inorganic content of the cells may modify certain enzymatic actions connected with normal organic metabolism, and in this way the increases of magnesium in plasma and cells which accompany the increased level of potassium after adrenalectomy[21] are of much interest. The increase in magnesium content of muscle fibres is associated with an increase of adenosine triphosphate and phosphocreatine, presumably by inhibition by magnesium ions of adenosine triphosphatase and of phosphokinases. Here one may well have a link with the depression in muscular activity, and of growth and heat production seen in adrenal insufficiency.

SOME ASPECTS OF MICRONUTRIENT ELEMENT METABOLISM IN PLANTS*

By Dr. E. J. HEWITT

Agricultural Research Council Unit of Plant Nutrition (Micronutrients), Long Ashton Research Station, University of Bristol

Experimental methods and problems. At present ten micronutrient elements, iron, manganese, copper, zinc, boron, sodium, molybdenum, chlorine, vanadium and cobalt, and six macronutrients satisfy criteria of essentiality for some plant organisms. Quite recently, recognition of molybdenum, chlorine[1] and vanadium[2] resulted either from the use of pure salts initially, regardless of later treatments, or from observation of growth increments due to vanadium in unpurified ferric chloride or to chloride provided by cobalt chloride. Further knowledge may depend on avoiding contamination in containers, water, reagents[3], seeds and the atmosphere[1]. Levels of deficiency shown recently for chloride[1], sodium, and vanadium[2] appear to exceed greatly those of 5×10^{-6} p.p.m. or less necessary to show a deficiency of molybdenum[4,5]. Since there may be about 10^{6} atoms of molybdenum in deficient cells[6] it may be necessary further to decrease the supply of some elements by a factor of 10^{3} before judging requirements, though negative results cannot be decisive. Total or partial replacement between elements, for example, calcium/strontium, molybdenum/tungsten, molybdenum/vanadium, potassium/rubidium/sodium, or of function, as in the case of molybdenum in nitrate reduction[7], which can be bypassed[8], may modify absolute, as well as quantitative, requirements.

Effects of micronutrients on growth. Mineral deficiencies and excesses have reproducible effects of diagnostic importance in many plants, and reflect reproducible metabolic states. Diverse symptoms may appear in different species, although the roles of many elements are probably general. The diversity may result from quantitative differences between plants in the distribution and activity of particular systems during growth, especially where two or more related enzymes depend on the same metal, or in qualitative differences in metabolism. Thus, the lesions in barley deficient in potassium are due to accumulation of putrescine, which is not observed in flax. Large changes may occur in the levels of free amino-acids and amides[9–11], especially with deficiency of zinc[11]. The pattern produced may vary with both deficiency and plant, and L+isoleucine and L hydroxyproline may induce severe abnormalities.

Indoleacetic acid 'oxidase'. A mechanism for the oxidation of indoleacetic acid occurs widely. Early experiments suggested that a hæm enzyme, possibly peroxidase, was involved and that some interaction occurred with manganese. Galston and others[12,13] suggested that the 'oxidase' system in pea epicotyl comprised a flavoprotein and a peroxidase that mediated a peroxidative reaction between the product of the initial oxidation by the flavoprotein, and hydrogen peroxide produced in this first step, which was regarded as photosensitive; the crude action-spectrum suggesting that of riboflavin. Kenten[15] and Stutz[16] showed that purified peroxidases and a monophenol co-factor comprised 'oxidase' systems without any flavoprotein component. Waygood and associates[17,18] have elucidated several points. The manganic ion, when stabilized as manganiversene, initiates non-enzymic decarboxylation and is reduced to the manganous form. The liberation of a hydrogen ion and a skatole free radical (I) is inferred. This is assumed to take up oxygen spontaneously to form a free radical of a skatole peroxide (II). In the presence of a peroxidase this oxidizes a monophenol co-factor which regenerates a manganous ion by the Kenten and Mann system[19], and yields a stable yellow product (III). The autocatalytic reaction is initiated by traces of manganic ion generated by various means

---

* Summary of three public lectures given to Biochemistry Department, University College, London, on May 20 and 27 and June 3. Details will be included in a review to be published in the *Biological Reviews of the Cambridge Philosophical Society*.

—such as light and riboflavin, or scopoletin, resorcinol and peroxidase[15], or illuminated chloroplasts—and is observed *in vivo*.

The effect of manganese is complex and specific[16]. Inhibition may occur in citrate buffers[14,16] or in crude extracts. Stimulation may occur over a wide range[16,18] in phosphate buffers, depending on the presence of monophenol co-factors or following lag-periods in the uptake of oxygen[15], which may invalidate observations made over single intervals of time[14]. The diverse effects of manganese are related to competition for peroxidative capacity, between the indoleacetic acid/monophenol/manganous ion system and O-diphenols which reduce[16], or citrate and pyrophosphate which inactivate, trivalent manganese[16,19].

The nature of the reaction products, the role of peroxidase and the production of hydrogen peroxide require re-examination. The reaction involves the uptake of one mole of oxygen and production[16] of one mole of carboxyl carbon dioxide for each mole of indoleacetic acid oxidized[15,16,18]. Several products may occur[16], although a yellow one (III), apparently identical with that obtained non-enzymically, may predominate[18]. One or more products may contain a carbonyl group and the indole configuration[16], and possibly a phenolic group. The production of a hydroxy-amino-acetophenone with formate and carbon dioxide demands the uptake of 1·5 *M* of oxygen and does not account[4] for peroxidase action. The production of a 3 methyl-2, 3-dioxindole, $C_9H_9O_2N$, *via* a hydroperoxide does not account for a peroxidative step and implies non-oxidative decarboxylation, which is contrary to evidence for the reduction of trivalent manganese[17]. Waygood and others[18] suggest the formula $C_9H_9O_2N$ for the yellow product (III). A weakness of their scheme is that the normal peroxidative mechanism is replaced by transfer of hydrogen from the monophenol donor to an organic peroxide (II), which retains all its oxygen without the production of water or of a hydroxyl group.

An alternative idea is that the postulated skatole free radical (I)[15] undergoes rearrangement, forming a methylene group and a nuclear free radical (IV). The uptake of oxygen producing a peroxide (V) might, with peroxidase, yield a stable carbonyl product C_9H_7ON (VI), with the indole structure, and give peroxidase II directly without formation of peroxidase I, as found for the dihydroxymaleic oxidase mechanism. This would be consistent with reactions between peroxidase and oxidizing agents other than hydroperoxides, which yield peroxidase I and II. Peroxidase II, which has only one oxidizing equivalent, could regenerate one manganic ion for each cycle[19]. Enolization might produce a hydroxyl compound (VII) accounting for two similar compounds. Non-enzymic reaction between the skatole peroxide (V) and indoleacetic acid, as postulated by MacLachlan and Waygood[15], could yield the same product (VI) as with peroxidase. For autocatalysis, trivalent manganese must be formed in excess of the initiating trace. The reactive free radical peroxide (V) might react either with a monophenol directly as postulated[18], giving a semiquinone equivalent to one manganic ion and a hydroperoxide (VIII). This might produce peroxidase I with two oxidizing equivalents, able to generate two manganic ions and also yield a third compound (IX), C_9H_9ON, with a hydroxyl group, potentially forming an ideal peroxidase substrate, which would be converted to (VI) at the expense of trivalent manganese by competing with the monophenol for peroxidase I and II. The proportions of (VI), (VII) and (IX) would not affect the stoichiometric requirement for 1 mole of oxygen and would depend on the availability of monophenol, manganese and peroxidase. The oxidation-reduction potential and stability of the manganic compound, such as the versenate, may be critical[17]. Natural monophenols may stabilize trivalent manganese with the correct potential[17], and form a co-factor complex for the 'oxidase' system. Whether hydrogen peroxide is formed is uncertain. Pure or dialysed catalase can replace peroxidase at pH 5–6·3 [16], but catalase or colloidal platinum may inhibit at pH 6·5–7·0 [15]. The quenching of fluorescence of scopoletin during indole acetic acid oxidation and adaptive peroxidase production in response to indoleacetic acid do not preclude organic peroxide action.

Molybdenum nutrition of plants. Plants deficient in molybdenum and grown with nitrate show many effects[21,22] that can be explained by the role of molybdenum in nitrate reductase[7]. Other effects not apparently related to low nitrate reductase activity also occur, including generally decreased ascorbic acid[23], decreased sugars in cauliflower, decreased organic/inorganic phosphate ratios in tomato and cauliflower[24,25] and apparently increased content of adenylic acid in cauliflower.

These changes are generally independent of the source of the nitrogen used to grow the plants[10,21,22]. Deficiency of molybdenum increases levels of certain amino-acids in cauliflower, given ammonium compounds, urea, or glutamic acid, whereas chlorophyll content is scarcely affected. The leaf malformation of cauliflower known as whiptail[20] occurs with deficiency of molybdenum with all nitrogen treatments[22]. With nitrate nutrition, whiptail occurs with a critical supply of molybdenum which allows considerable nitrate reduction but is inadequate in some other respect. Oxidation of ascorbic acid in cauliflower leaf and acid phosphatase activity in tomato are apparently increased by deficiency of molybdenum, whereas dehydrogenase action may be less. Nitrate reductase may be adaptive in fungi[26] and cauliflower[27] in regard to supplies of both molybdenum and nitrate (or nitrite). Attached and excised tissues of cauliflower, deficient in molybdenum and grown with ammonium sulphate, require molybdenum and nitrate for a production of enzyme which can be detected after a lag-period of one or two hours. Addition of molybdenum to cauliflower leaf disks[28] increases the respiratory quotient during reduction of accumulated nitrate after a similar lag-period. Addition of molybdenum to deficient tomato plants grown with nitrate causes increase in nitrite after a lag-period of about one hour[29], and levels of free amino-acid increase after an *initial decrease* during the first hour[12]. These changes are consistent with synthesis of an adaptive enzyme. Suppression of light for 4–6 days or air for 48 hours[27] also depresses the activity of nitrate reductase, which recovers rapidly on restoring normal conditions. Absence of an inductive metal constituent required for the synthesis of a specific enzyme may release template sites for abnormal competitive synthesis of other enzymes, or molybdenum may fulfil more than one specific role. In *Scenedesmus obliquus*[8] vanadium may have acquired one function usually fulfilled by molybdenum, since both elements are needed together with nitrate, whereas molybdenum may be unnecessary with urea or ammonium carbonate in this organism[8].

Multiple metal activation and differential enzyme activity. In enzymes of the tricarboxylic acid cycle optimum requirements of manganese *in vitro* range from about $10^{-2} M$ for 'malic' dehydrogenase and oxaloacetic decarboxylase in parsley root to about $5 \times 10^{-4} M$ for isocitric dehydrogenase in *Avena* coleoptile or *Phaseolus* leaf. Cobalt at $7 \cdot 5 \times 10^{-4} M$ is equivalent to manganese in one enzyme, but at $4 \times 10^{-3} M$ gives only 55 per cent of the value for manganese in another and is toxic to glutamic dehydrogenase in *Avena*, whereas magnesium at $10^{-3} M$ and $10^{-2} M$ gives 80 and 10 per cent respectively of the values for manganese. Manganese at $3 \times 10^{-3} M$ is specific for the reduced triphosphopyridine nucleotidase in wheat germ, whereas manganese or magnesium at $4 \times 10^{-3} M$ is equivalent for the reduced triphosphopyridine nucleotide glutathione reductase. Isocitric, malic and glucose-6-phosphate dehydrogenases can be linked to glutathione reductase in many plants[30], but show unrelated activity over a wide range. The effects on the malic and isocitric systems of adding manganese *in vitro* vary greatly, from 15-fold increase to slight inhibition[29]. Similar differential effects occur with hexokinase, phosphohexokinase, and 2–3 diphosphoglyceric phosphotransferase in several plants where magnesium and manganese are interchangeable, and cobalt can activate the last. Nineteen enzymes activated by magnesium in yeast attain 50 per cent of maximum activity between about $3 \times 10^{-5} M$ and $4 \times 10^{-3} M$. The absence of marked optima permits maximum activity at $10^{-2} M$ in seventeen of these enzymes, but riboflavin phosphate pyrophosphorylase is then decreased to 50 per cent of maximum. Manganese may replace magnesium in at least fourteen enzymes with an efficiency ranging from less than 30 per cent, to one equal or nearly double that of magnesium, whereas cobalt *in vitro* replaces magnesium at double its efficiency in riboflavin kinase. Competitive inhibition by activating metals also occurs, and certain concentration combinations may be unfavourable. These examples also suggest reasons for diversity in the requirements for micronutrients and in the symptoms of deficiency.

Mineral deficiencies and enzyme pattern. Organisms deficient in certain minerals may lack activity of enzymes directly dependent on the deficient element. Deficiency during growth appears to prevent synthesis of the metalloprotein enzymes and no reactivation occurs on adding the metal to the *extract*[26, 27, 31]. The dissociable isocitric and malic enzymes, however, may be present though inactive in the *extract* from a deficient plant and are reactivated on adding the metal[32]. Differential decreases in activity may occur under conditions of deficiency when several enzymes depend on the same metal.

Enzymes not dependent on the deficient element may show greatly increased activities[21–23], which decrease to normal in 2–6 days when the deficiency is corrected, while the activity of the respective metallo-enzymes is restored[21]. Increases in peroxidase with deficiency of zinc[21], or in phenol oxidase with deficiency of boron[21, 24], appear consistent in many plants, but trends may also vary. Several deficiencies may produce a similar change in one enzyme, such as acid phosphatase or peroxidase[21]. Interactions between antagonizing elements, such as cobalt and iron[25], or iron and manganese, may show analogous effects. Some mineral disorders may reflect the integrated effects of such abnormal but reproducible enzyme patterns.

The changes in the amino-acid pool might be expected to affect enzyme synthesis, but present evidence does not support this idea. The lack of one enzyme might cause adaptive increases in others due to increases in substrates for alternative systems. The accumulation of chlorogenic and caffeic acids in plants deficient in boron[24] might increase polyphenolase activity[21, 34]. *Neurospora* deficient in zinc contains negligible alcohol dehydrogenase[33]. Several dehydrogenases linked by diphosphopyridine nucleotide[37] appear to be zinc metallo-enzymes and much of the diphosphopyridine nucleotide may be bound by the enzyme[38]. If these points apply to *Neurospora*, an adaptive increase in diphosphopyridine nucleotase[35] might result from increased free diphosphopyridine nucleotide due to non-synthesis of the apo-enzymes. It has recently been reported[39] that diphosphopyridine nucleotase activity is greatly decreased for bound diphosphopyridine nucleotide on active glyceraldehyde-3-phosphate dehydrogenase.

OBITUARIES

Prof. H. U. Sverdrup

Harald Ulrik Sverdrup, who died very suddenly on August 21, was born in November 1888. He was a relative of Otto Sverdrup, who had been Nansen's captain on the *Fram* and who was himself the discoverer of a great fjord region west of Ellesmere Land.

Sverdrup became assistant to Prof. Bjerknes in Oslo in 1911, but during 1913–17 studied in Leipzig. From 1917 until 1925 he was leader of research on the *Maud* Expedition led by Roald Amundsen and during this period obtained an intimate knowledge of the Arctic. He was appointed a Research Fellow at the Carnegie Institution of Magnetic Research in 1922. From 1926 until 1931 he was professor of meteorology in the Geophysical Institute in Bergen. In 1931, when Sir Hubert Wilkins planned an expedition towards the North Pole in the submarine *Nautilus*, Sverdrup gave him full support. Unfortunately, apart from dives at the edge of the sea ice, Wilkins was never able to carry out his plans and the submarine was scuttled off Bergen in November of that same year. In 1934 Sverdrup took part in an expedition to North West Spitsbergen, with his close friend, Prof. H. W. Ahlmann, to study heat exchange between the atmosphere and the snow surface in these high latitudes. Sverdrup was appointed director of the Scripps Institution of Oceanography in California and was professor in the University of California during 1936–48. He was invited to become director of the Norwegian Polar Institute in 1948 and in 1949 became professor of geophysics in the University of Oslo.

H. U. Sverdrup's career was quite unusual, and there is no one else who has ever combined a special knowledge of mathematics and physics with familiarity in the field with problems both in the Antarctic and in the Arctic. He is known to a very large number as one of the three authors, the others being Martin W. Johnson and R. H. Fleming, of "The Oceans", published in 1942, which will long remain the most extensive text-book on oceanography. He is equally well known, however, to the smaller number who have been associated with him in polar science. Sverdrup was responsible for the home control of the Norwegian–British–Swedish Expedition to Queen Maud Land in 1949–52, and himself visited Maudheim in January 1951. His polar knowledge was extremely varied. Anyone anxious to obtain information, for example, on sea ice would rely very largely on Sverdrup's opinion, and his views on this subject were invaluable at the time that the Royal Society's Expedition to Halley Bay was under consideration. This, however, was only one of the many fields of rare and unusual knowledge which he covered and which have made him unique among explorers.

J. M. Wordie

Prof. W. N. Benson, F.R.S.

With the death on August 20 of emeritus professor W. N. Benson, of the University of Otago, New Zealand has lost the doyen of her geologists. He passed away after a brief illness, although his general health had given concern for some time.

William Noël Benson was born near London on December 26, 1885, the son of an Australian shipping manager. He was educated at the Friends' High School in Hobart and later at the University of Hobart and the University of Sydney, where he came under the influence of the inspiring personality and teaching of Sir Edgeworth David. While still at Sydney, and before even graduating B.Sc. in 1907, he published a paper on the contact aureole of a granitic body. This early irruption into the field of original inquiry initiated a career that was always devoted primarily to research. The topics he investigated were to involve work in virtually all the geological sciences, though he made especially significant contributions on the interplay of tectonics and magmatism. His work was followed with extraordinary energy, enthusiasm and persistence. All his former students will remember his well-loved figure forging ahead in front of panting field-parties, and in his office, when too tired for other work he would turn to drafting maps and block diagrams, an occupation which, he maintained, did not require great mental effort. He handled a very heavy teaching load, being professor of geology in the University of Otago without any assistant during 1916–26 and with only one assistant (F. J. Turner) for all but three of the remaining years before he retired from active teaching at the end of 1949.

In 1908 Benson acted for a year as lecturer in mineralogy and petrology in the University of Adelaide. Three papers followed, two of them on petrological problems and one on the fault-block structure of the Mt. Lofty Ranges. Back in Sydney during 1909–11 as demonstrator in petrology, he began his classic study of the geology and petrology of the Great Serpentine Belt of New South Wales, which he continued first as 1851 Science Research Scholar at Cambridge under Harker, Bonney and Marr (1911–13), and later (1914–16) as Research Fellow and lecturer in Sydney. The resulting long series of papers culminated in two notable publications that appeared after his appointment to Otago—"The Origin of Serpentine" (1918) and "Tectonic Conditions accompanying the Intrusion of Basic and Ultrabasic Igneous Rocks" (*Mem. U.S. Nat. Acad. Sci.*, 1926).

In Dunedin, he quickly turned his attention to problems of New Zealand geology as well as its relation to the south-west Pacific as a whole. He carried out important researches on New Zealand's then little-known Ordovician rocks and on their graptolite faunas. His geomorphic observations in Fiordland and in the Dunedin district led to the important concept of both a Cretaceous peneplain in the South Island, and a late Cainozoic erosion surface truncating it and later sediments. He also showed that the so-called block mountains of eastern Otago are essentially fault-folds of more or less Saxonian type. His last major discovery was that of the first Cambrian rocks to be found in New Zealand, a brief account of which was published shortly before his death. Benson's major work in New Zealand, however, was undoubtedly his long and detailed study of the late Cainozoic East Otago Petrographic Province. Numerous papers on this and on related topics have already appeared, but a comprehensive memoir is still to be published. Progressive crustal movements are shown to have occurred during the eruption of repeated differentiation cycles of basic and alkaline volcanic rocks.

During his life-time Benson received many honours. He was a foundation Fellow of the Australian and New Zealand Association for the Advancement of Science, and its Mueller Medallist (1951); Fellow of the New Zealand Institute, later Royal Society of New Zealand (1926); Hector medallist (1933), Hutton medallist (1944) and president (1945–47) of the same Society; Lyell medallist of the Geological Society (1939); Fellow of the Royal Society (1941); Clarke medallist of the Royal Society of New South Wales (1945); correspondent of the Geological Society of America (1949); honorary D.Sc., University of New Zealand (1951), and honorary member of the Mineralogical Society (1954).

Benson looked upon himself as a geological child of Sir Edgeworth David, and he always spoke of his old chief with the greatest reverence and affection. There is now another geological family, that of W. N. Benson himself, whose members are spread throughout the world. He has left them—and science as a whole—well over a hundred published memoirs, papers and notes recording his researches and his scientific philosophy, written in his own characteristic style. Above all he has left them the memory of himself, which lives on in the ever-widening circle of his geological descendants.

He is survived by his wife, formerly Miss Helen Rawson, who was professor of home science in the University of Otago at the time of their marriage in 1923. D. S. COOMBS

Dr. Charles Todd, O.B.E., F.R.S.

CHARLES TODD died at Croydon on September 22. He was born in 1869, coming of farming stock in Cumberland. After ill-health as a small boy, he received an education, mainly classical, at Carlisle Grammar School, but succeeded in obtaining an open scholarship in physics and chemistry at Clare College, Cambridge, in 1888. In due course he obtained a Class I in the Natural Science Tripos, proceeding to St. Bartholomew's Hospital with an open scholarship and qualifying in 1894. After several clinical appointments he became interested in public health problems while working at the London Fever Hospital. In 1900 he became assistant bacteriologist to the serum department of the Lister (then Jenner) Institute and worked on antitoxins with George Dean and later G. F. Petrie. Here he demonstrated the existence of a toxin produced by Shiga dysentery bacilli. He went to Egypt in 1904 to help to make antisera against cattle plague, of which there was a serious outbreak there. This led to an appointment as bacteriologist and afterwards director of the Hygienic Institute in Cairo, and he finally spent twenty-one years in Egypt. In 1906 he was investigating scorpion venom and found out how to make an antiserum. But cattle plague remained a major interest and he made valuable contributions to our knowledge of the disease.

His most important scientific work arose incidentally out of this, for, with R. G. White, he found that cattle repeatedly injected with virulent blood developed isolysins in their sera. The cellular individuality of cattle thus came to light: and Todd and White showed that with suitably absorbed sera the blood cells of any individual could be distinguished from those of any other.

In 1925 Todd left Egypt, having worked on many aspects of public health and received many honours. In 1926 he was given a research grant to work at the National Institute for Medical Research at Hampstead. Here he continued his studies on cellular individuality, now using fowls, in which isohæmagglutinins were readily produced. As with cattle, he found that with absorbed sera he could pick out bloods of individual fowls. He went further and determined that the immunological specificity was inherited: polyvalent sera absorbed with cells of both parents had no action on the cells of their chicks.

At Hampstead Todd worked also on fowl plague and described a 'dilution phenomenon' in which just neutral serum–virus mixtures had their activity restored by dilution. With Perdrau he made studies of the photodynamic action of methylene blue on bacteriophage and other viruses. He finally retired in 1940.

Todd was a delightful and helpful colleague with a great zest for life and a wonderful sense of fun. He had a wide knowledge of public health and microbiology and knew not a little about physics. He delighted in 'Heath-Robinson' gadgets, had a very critical mind and scorn for pretentiousness. He was elected Fellow of the Royal Society in 1930. He was unmarried. C. H. ANDREWES

Dr. R. O. Page

WITH the death of Robin O. Page, which occurred on July 14 in Christchurch, New Zealand, the science of leather chemistry has suffered a heavy loss. Robin Page was born in 1897 at Christchurch, New Zealand, which was to become his residence for the rest of his life. During his college years he distinguished himself as a scholar and in various sports; he even represented his country in athletics. After receiving the master's degree with first-class honours in chemistry at University College, Canterbury, in 1920, he joined the staff of Woolston Tanneries, Ltd., Christchurch, as a chemist. He was appointed works manager in 1924—a position which he held up to his death.

At an early age he was fascinated by the intricate problems of the mechanism of tanning reactions; an interest which followed him all through his active life. To his inquiring mind the fundamentals and theoretical concepts were vital exigencies. In addition to carrying responsibility in the industry, Page not only kept himself informed about current scientific progress but also contributed a distinguished series of more than twenty original papers—the result of the research which he carried out alongside his practical duties for the love of the great unknown of his 'bread and butter' reactions.

Page was one of the first investigators to realize the importance of the physico-chemical approach in the elucidation of tanning processes, being inspired by the new ideas of the early 'twenties, propounded by Jacques Loeb and John Arthur Wilson, on the behaviour of proteins. This is shown by his lucid papers on ion effects on collagen published in 1927. The subsequent main contributions of Page concern the mechanism of the vegetable tannage. With his sound conception, thorough knowledge of chemistry and critical outlook, the tannery experience became to him a solid background for these pioneering investigations. Among his more recent publications, his clarifying investigation of the classical tannin–

gelatin reaction—first studied by Humphry Davy in 1803—should be especially mentioned for its explicity of technique and sound theorization. These papers, published in British and American journals, made Page an outstanding figure in contemporary leather research.

His scholarly endeavour was early recognized, not only by his own colleagues. Thus, the University of New Zealand conferred the degree of D.Sc. upon him in 1934. Dr. Page took an active part in the scientific life of his own country, being a Fellow of the Royal Institute of Chemistry, a Fellow of the New Zealand Institute, also a past president of that body, and a Fellow of the Royal Society of New Zealand. During overseas visits to Europe and the United States he made many friends. The man and his achievements carried the imprint of sterling qualities.

K. H. Gustavson

NEWS and VIEWS

Royal Society Medal Awards

The following awards of medals have been made by the President and the Council of the Royal Society: *Copley Medal* to Sir Howard Florey, professor of pathology in the University of Oxford, for his distinguished contributions to experimental pathology and medicine; *Davy Medal* to Dame Kathleen Lonsdale, professor of chemistry at University College, London, for her distinguished studies in the structure and growth of crystals; *Buchanan Medal* to Sir Neil Hamilton Fairley, for his distinguished contributions to the control of malaria; *Hughes Medal* to Prof. J. Proudman, professor emeritus of oceanography in the University of Liverpool, for his distinguished work on dynamical oceanography.

Royal Society of Edinburgh: Officers for 1957–58

The following have been appointed to the Council of the Royal Society of Edinburgh for the session 1957–58: *President*, Prof. James Ritchie; *Vice-Presidents*, Prof. J. Norman Davidson, Principal H. B. Nisbet, Prof. Meirion Thomas, Prof. A. C. Aitken, Dr. J. E. Richey and Prof. D. Whitteridge; *General Secretary*, Prof. Norman Feather; *Secretaries to Ordinary Meetings*, Dr. T. R. Bolam, Dr. A. W. Greenwood; *Treasurer*, Dr. J. R. Peddie; *Curator of Library and Museum*, Dr. Douglas Guthrie; *Councillors*, Dr. D. A. Allan, Prof. G. H. Bell, Dr. D. N. McArthur, Dr. A. G. MacGregor, Prof. C. H. Waddington, Dr. J. A. Macdonald, Dr. R. Schlapp, Dr. J. B. Tait, Prof. G. M. Wyburn, Prof. R. A. Rankin, Prof. A. E. Ritchie and Prof. W. M. Smart.

Royal Society of South Africa: Elections

The following have recently been elected to fellowship in the Royal Society of South Africa: Dr. R. A. Alexander, director of veterinary services, South Africa, Onderstepoort, Pretoria; Dr. J. J. Frankel, Department of Geology and Mineralogy, University of Natal, Durban; Prof. I. Gordon, professor of pathology and dean of the Medical Faculty, Medical School, Durban; Prof. F. G. Holliman, professor of organic chemistry in the University of Cape Town; and Dr. R. H. Marloth, director of the Citrus and Subtropical Horticultural Research Station, Nelspruit, Transvaal.

Organic Chemistry at Glasgow:

Prof. R. A. Raphael

The appointment of Ralph Alexander Raphael to the regius chair of chemistry at Glasgow brings him back to the University where he held a lectureship during 1949–54. He graduated from the Imperial College of Science and Technology, London, in 1941, with first-class honours, and obtained the Ph.D. degree in 1943. After a period with Messrs. May and Baker, Ltd., he returned to the Imperial College in 1946 with an Imperial Chemical Industries Fellowship. His distinction as an organic chemist won early recognition when he was awarded the Meldola Medal for 1948 at the age of twenty-seven. His main interest in research has been the study of acetylenic compounds and, in particular, the use of such reagents as precursors in the synthesis of a wide range of naturally occurring organic substances. In 1954, Dr. Raphael became the first professor of organic chemistry at The Queen's University of Belfast. The combination of his skilful leadership and his enthusiastic personality led to a rapid expansion of the research school in organic chemistry during his three years at Queen's; his outstanding success there as a teacher and as a director of research augurs well for the future of organic chemistry in Glasgow.

Organic Chemistry at Belfast:

Prof. H. B. Henbest

The appointment of Dr. H. B. Henbest to the chair of organic chemistry at The Queen's University of Belfast, in succession to Prof. R. A. Raphael, certainly represents an example of a meteoric rise. Graduating with first-class honours at the Imperial College of Science and Technology, London, in 1944, he worked under Prof. (then Dr.) E. R. H. Jones, a collaboration he was enabled to continue after his doctorate by the award of a Beit Research Fellowship. Henbest accompanied Jones to Manchester on the latter's appointment to the chair in 1948, and remained there as a lecturer in organic chemistry until 1956; this was punctuated by a year's leave of absence, during which he worked at Harvard and the University of California, Los Angeles. Only shortly before the appointment to Queen's he had moved to King's College, London, as reader in organic chemistry.

The outstanding impression of Henbest's research work is its lack of triviality and its concentration on important and live topics. His first conjoint project was the establishment of an improved route to provitamin D_3, and, continuing his steroid interests, he played a large part in devising a new route to cortisone from ergosterol. Another outstanding achievement in the vitamin field was the establishment of the structure of vitamin A_2 by an unambiguous synthesis. A logical extension of interest to plant hormones led to synthetic work in relation to the postulated structure of auxins *a* and *b*, and to the isolation and proof of structure of a new plant hormone, 3-indolylacetonitrile. Aspects of acetylene chemistry have also engaged his attention, leading, for example, to the synthesis of kawain. At present he is engaged on a series of highly original stereochemical investigations of a fundamental nature, which have considerable potential use in the stereoselective elaboration of organic molecules. His appointment coincides happily with the fruitful expansion of these investigations and with his new department's move to its palatial new quarters in the near future.

Royal Military College of Science, Shrivenham : Prof. A. Charlesby

DR. ARTHUR CHARLESBY, who has been appointed professor of physics at the Royal Military College of Science, Shrivenham, is forty-one years of age, and was educated in London and at the Royal Atheneum, Antwerp, and the University of London, where he obtained a Ph.D. in 1939, and where he was afterwards engaged in research and teaching until 1942. After a period in the scientific research department at the Ministry of Aircraft Production he served with the R.A.F. until 1945, during which time he was engaged on operational research into the scientific aspects of aerial warfare in the Mediterranean. During 1949–54 he was a principal scientific officer at the Atomic Energy Research Establishment, Harwell, where he was in charge of a group studying the effects of atomic radiation on materials. He obtained a D.Sc. in 1954. For the past two years he has been head of the Radiation Department of Tube Investments Research Laboratories. He has written numerous papers on solid state and nuclear subjects and is the editor of an international series of books on the effects of atomic radiation.

Prof. A. D. S. Carter

PROF. ALFRED DENIS SNOWDON CARTER, who has been appointed professor of mechanical engineering at Shrivenham, is thirty-five years of age, and was educated at Neath Intermediate School and at the University of Wales. After short periods of research at the Royal Aircraft Establishment and with Power Jets (Research and Development), Ltd., he joined the National Gas Turbine Establishment in 1946, since when he has been working on aerodynamic and vibration problems connected with the gas turbine. He has published many papers on blade theory and performance, on the axial compressor, and on vibration problems associated with the gas turbine. Prof. Carter is a member of various Government scientific committees and an active member of the Institution of Mechanical Engineers ; during 1952–55 he was a member of the Council of the Institution.

Prof. A. Lee

PROF. ALAN LEE, who has been appointed professor of electrical engineering (radar and telecommunications) at Shrivenham, is fifty years of age, and was educated at Todmorden Grammar School and at Emmanuel College, Cambridge, where he read mathematics and mechanical sciences. After a short period of research in industry and teaching at the R.A.F. Electrical Wireless School, Cranwell, he joined the Royal Military College of Science in 1935. He has been head of the Radar and Telecommunications Branch since 1941. He has been a member of a number of Government committees connected with his subject.

Advisory Council

THE following have been appointed to the Advisory Council of the Royal Military College of Science to replace members whose terms of office had expired : Prof. J. Diamond, of the University of Manchester ; Prof. M. H. L. Pryce, of the University of Bristol ; and Mr. R. P. Bell, of Balliol College, Oxford.

Laboratory of Cryptogamic Botany, University of Manchester : Mr. E. Ashby

AFTER forty-seven years of service as chief steward and technician in the Laboratory of Cryptogamic Botany of the University of Manchester, Mr. Ernest Ashby will retire on November 25. He joined the laboratory soon after the appointment of Prof. W. H. Lang as the first occupant of the Barker chair of cryptogamic botany and continued with Prof. C. W. Wardlaw on his appointment in 1940. Over this long period, Mr. Ashby's talents for growing plants, often of a difficult and wayward nature, and for preparing materials for microscopic study, have been of great value in the research and teaching activities of the laboratory ; and many have gratefully acknowledged his help. Perhaps most of all, his love of photography and photomicrography, and his zest for the achievement of perfection in them, have made a notable contribution to botanical illustration. The value of his work was recognized during the year by the conferment upon him by the University of the honorary degree of Master of Science. His many friends and associates have welcomed this signal honour and will wish him well in his retirement.

Royal Society Antarctic Expedition : Mr. Joseph MacDowall

MR. JOSEPH MACDOWALL has been appointed leader of the Royal Society International Geophysical Year Antarctic Expedition at Royal Society Base, Halley Bay, from January 1958 until the party returns to the United Kingdom in the spring of 1959. He succeeds Col. Robin Smart, R.A.M.C., the present leader, who accepted the appointment only for the current year. Mr. MacDowall, who was seconded to the expedition from the Meteorological Office, Air Ministry, where he holds the rank of senior scientific officer, is aged thirty-one. He was educated at Wallasey Grammar School and served in the Royal Naval Air Arm during 1946–48. For the next three years he studied at St. John's College, Cambridge, and then joined the Meteorological Office, where he worked at Kew Observatory and in the Instrument Division. Mr. MacDowall went to Halley Bay in November 1956 as leader of the meteorological and geomagnetic group which has been responsible for making the surface and upper air meteorological observations at Halley Bay since the International Geophysical Year began on July 1, 1957, together with observations of the Earth's magnetism and the accumulation of ice and snow in past years.

Orbit of the Second Artificial Earth Satellite

THE time of launching of the second Russian artificial Earth satellite is as yet unknown, but it was first detected in Britain with the Cambridge radio interferometer on November 3d. 05h. 58m. The satellite has been observed since then both visually and by radio methods. An orbit telegraphed to the British Astronomical Association from Copenhagen (*Brit. Astron. Assoc. Circular*, No. 391 ; November 8, 1957) gives equatorial elements computed by Cunningham for epoch November 4·0 :

M	151°	φ	6° 02′ (e 0·105)
ω	44	a	1 1403
Ω	118	Daily change in ω	+ 0·6°
i	65° 30′	,, in Ω	− 3 1

(The major axis is presumably quoted in terms of the Earth's equatorial radius.) These values are supported by elements computed by the Mullard Radio Astronomy Observatory, Cambridge, which gives a somewhat larger inclination, namely, 65°, and a period of 103m. 40s. The figures, which should be regarded as tentative since they are based on a few observations only, lead to heights at perigee of 250 km. and at apogee of 1,630 km.

The observable passages of this satellite near the British Isles occur at present between 5h. and 15h. each day, and it can be seen as a bright object (magnitude − 1 to + 1) when suitably placed before dawn. Since 14 revolutions occur in 1,451m. 5s., the tracks repeat themselves 11m. 3s. later each day, and this interval, together with the regression of the nodes, causes the tracks to swing westwards about 7° per day.

Russian Earth Satellites and the International Geophysical Year

In a written reply to a question regarding scientific information on the first Russian Earth satellite in the House of Commons on November 1, M. H. Nicholls, the Parliamentary Secretary to the Ministry of Works, representing the Lord President of the Council, said that the Royal Society and not the Department of Scientific and Industrial Research is responsible for co-ordinating United Kingdom participation in the programme of the International Geophysical Year. The appropriate committee is considering the arrangements for collecting scientific information obtained in Britain from the Earth satellites and transmitting it to the World Data Centre of the International Physical Year for publication. In addition, it was understood that arrangements were in hand for an account of some British observations of the satellite to be published.

Theratron Cobalt-60 Beam Unit at Westminster Hospital

At Westminster Hospital, London, on November 4, the Lord Chancellor, the Right Hon. Viscount Kilmuir, unveiled a commemoration plaque and so put into commission a theratron cobalt-60 beam unit that is a gift to the Hospital, through the British Empire Cancer Campaign, from Mr. and Mrs. Michael Wix. This apparatus, made by Atomic Energy of Canada, Ltd., is the second theratron to be installed in Great Britain, and is designed to permit moving-beam treatment of malignant disease while the patient lies upon a couch that forms an integral part of the equipment. An additional feature of this second theratron is a facility that permits the couch to be moved to and fro simultaneously with the rotation or other movement of the beam. Also, all adjustments of the couch in order to arrange a patient precisely for treatment are electrically powered so that a single 'joy-stick' switch readily permits movement up or down or to and fro. The cobalt source behaves effectively at approximately 1,500 curies and provides, at a distance of one metre, a dose-rate of 33 röntgens per minute.

During the proceedings before the unveiling ceremony, Sir Stanford Cade gave a brief historical survey of the Hospital's Radiotherapy Department, tracing the growth of its radiotherapeutic tools from a few milligrams of radium in 1922 to a 1-gm. radium unit in 1929 and then to the present when, in addition to conventional X-ray machines, it now has a two-million volt Van de Graaff generator, the theratron put into commission on this occasion and a caesium-137 beam unit that is now being assembled. Lord Kilmuir, in his address, emphasized that there is still a place within the National Health Service for the private benefactor who feels called upon to serve the welfare of his fellows. This gift of a theratron, which will benefit the unfortunate victims of cancer for many years to come, is a striking example of such service.

British Museum (Natural History) : The Stanwick Skull

Among the items reported to the Trustees of the British Museum at their meeting at the British Museum (Natural History) on October 26, was the gift by the Society of Antiquaries, London, of a human skull showing fatal wounds, found during excavations of the Roman fortifications at Stanwick, Yorkshire, during 1951–52. Examination of the skull showed that it was that of a man who had been violently attacked with a sword or axe, and afterwards beheaded. The slaying probably took place just before the capture of the Iron Age fortress by Roman troops in A.D. 71–74. It is uncertain whether the skull is that of a British native or of a patrolling Roman soldier. As it was found in the ditch close to the entrance of the fortress, and was not accompanied by other human bones, the head was probably displayed on the gate, and then became dislodged and fell into the ditch during the final attack. The skull is referred to by Sir Mortimer Wheeler in "The Stanwick Fortifications" (Report of the Research Committee of the Society of Antiquaries, 17, 533; 1954).

Fertility and Fertility Control

The first Oliver Bird Lecture was delivered by Dr T. Mann at University College Hospital Medical School, London, on November 6; he spoke on "The Biochemical Basis of Spermicidal Activity". The lecture was sponsored by the Society for the Study of Fertility and held under the auspices of the Oliver Bird Trust (see *Nature*, October 12, p. 737). Dr. Mann discussed the mechanisms of action of various compounds which render sperm incapable of fertilization, either by killing them, by inhibiting their motility, or affecting their fertilizing power without impairing their motility. The latter part of the lecture dealt with the biochemical aspects of the use of spermicides as contraceptive agents, and discussed some of the pitfalls in the way of equating spermicidal activity *in vitro* with contraceptive activity *in vivo*. The lecture was preceded by the first meeting of the Council for the Investigation of Fertility Control, which was set up by the Oliver Bird Trust to work with the Family Planning Association in the organization of tests and clinical trials of contraceptives in Great Britain and elsewhere.

Calouste Gulbenkian Foundation Grants

The Trustees of the Calouste Gulbenkian Foundation, Lisbon, have announced the Foundation's second list of grants, totalling more than £1 million. Among the grants for scientific, medical and other research (totalling £403,250) are the following: to the National Laboratory of Civil Engineering, Lisbon, up to £250,000 to build and equip a new research centre, the Calouste Gulbenkian Institute, for fundamental investigations in civil engineering; to Baghdad College, £50,000 towards a Gulbenkian science block for the new Jesuit university (Al-Hikma University); to the Sanatorium of Azounieh, Lebanon, £20,000 over three years for building a Calouste Gulbenkian Research Centre for Chest Diseases, to serve the Middle East, £10,000 for laboratory equipment, and £6,000 over three years towards the running expenses; to the Faculty of Medicine, University of Lisbon, £22,500 to install, equip and maintain for three years a laboratory of electron microscopy in the Institute of Histology and Embryology, and £18,500 to the Laboratory of Physiological Chemistry for essential materials and research; for a new Centre for Agricultural Economics in Portugal, £15,000 initially to establish and run the new centre as part of the Foundation's own activities; to the Sarawak Museum, British Borneo, £5,000 for the excavation during 1958 of the great cave of Niah in Subis Mountain (see *Man*, 57, 161, November 1957); to the Institute of Archæology, Faculty of Arts, University of Coimbra, £2,500 for archæological research in Iraq; to the Office of Town-Planning Research, Lisbon, £1,250 a year for three years. Other grants include Gulbenkian Fellowships, for which £15,000 has been set aside in the United Kingdom for three years to encourage co-operation between selected universities and teachers of mathematics, science and technology in nearby schools, technical colleges and training colleges, with the view of improving the quantity and quality of science teaching; and grants to undergraduate scientific expeditions from the United Kingdom, for which up to £2,600 will be granted over three years. The two expeditions assisted this year have been from the University of Cambridge to the Colombian Cordillera Oriental and to French West Africa. £2,000 has been allocated to the Mathematical Association, to finance the publication of the Association's authoritative reports and recommendations.

Indonesian Council for the Sciences

A COUNCIL has been established by Act of the Republic of Indonesia, under the name of "Madjelis Ilmu Pengetahuan Indonesia", to work in the scientific field in Indonesia. The tasks of this Council include: the promotion of science in Indonesia; advising the Government in scientific matters; encouraging the exchange of scientific information between Indonesia and the rest of the world; the direction of institutes; and the allocation of funds entrusted to it. Further information can be obtained from the Information Department of the Indonesian Council for Sciences, Medan Merdeka Selatan 11 pav., Djakarta.

Announcements

OWING to other commitments, the Rev. C. E. Raven has retired from the presidency of the Field Studies Council. The Rt. Hon. Lord Hurcomb has agreed to fill the office with effect from November 1.

THE Textile Institute has made the following awards: *Institute Medal* to Mr. G. Loasby, chairman of the Council of the Institute since 1955, in recognition of distinguished services to the textile industry in general, and to the Textile Institute in particular; *Service Medal* to Mr. H. Pomfret, honorary secretary of the Blackburn Section of the Institute for eleven years; and to Dr. P. P. Townend, Department of Textile Industries, University of Leeds, a former chairman of the Yorkshire Section of the Institute.

THE nineteenth annual congress of the British Institute of Radiology will be held at the Royal Horticultural Halls and the Napier Hall, Westminster, during November 27–29. Further information can be obtained from the General Secretary, British Institute of Radiology, 32 Welbeck Street, London, W.1.

A PROGRAMME of scientific films in colour, organized by the Society of Chemical Industry, will be shown at the Royal Empire Society, 18 Northumberland Avenue, W.C.2, on November 18, at 6.30 p.m. The films to be shown include "Canadian Wheat" (National Film Board of Canada); "Point of New Departure" (Imperial Chemical Industries Ltd.) on synthetic fibres with emphasis on 'Terylene'; "Coral Wonderland" (Australian News and Information Bureau); and "A Vitamin Emerges" (Glaxo Laboratories Ltd.) on the story of vitamin B_{12}. The meeting is open to members of the Society, who may bring friends.

A JOINT symposium on "Recent Developments in Industrial Low Temperature Gas Separation", organized by the Institution of Chemical Engineers and by the Low Temperature Group of the Physical Society, is to be held at the Royal Institution, Albemarle Street, London, W.1, on November 26. The papers read at the meeting will be published, together with a report of the discussion, in the *Transactions of the Institution of Chemical Engineers*. Further details and registration forms for those wishing to attend the symposium may be obtained from the Physical Society, 1 Lowther Gardens, London, S.W.7, or from the Institution of Chemical Engineers, 16 Belgrave Square, London, S.W.1.

THE first Sherrington Memorial Lecture of the Royal Society of Medicine will be delivered by Lord Adrian at 8 p.m. on November 27 in the Barnes Hall. The subject of the Lecture will be "The Analysis of the Nervous System". Admission to the Lecture, which is open to Fellows of the Society and their guests, is by ticket, obtainable from the Royal Society of Medicine, 1 Wimpole Street, London, W.1.

UNDER the provisions of the Fulbright Programme, travel grants are available to citizens of the United Kingdom and British Colonies to go to the United States for an academic or educational purpose, provided that they have the financial support in dollars for the visit, and have been accepted by an American institution of higher learning. The grants cover the cost of direct travel between the candidate's home and the United States and return, and are available during June 1, 1958–April 1, 1959. Applications must be submitted by March 15, 1958 (for those travelling between June 1 and August 15, 1958) or by June 1 (for those travelling after August 16). Application forms and further information can be obtained from the United States Educational Commission in the United Kingdom, 71 South Audley Street, London, W.1.

ERRATUM. In the article on the orbit of the first Russian Earth satellite in *Nature* of November 9, there is an error in the time of transit given in the last line of Table 1 on p. 938: for "05 hr. 29 min. 22 sec." read "05 hr. 28 min. 30 sec.".

RADIOISOTOPES IN SCIENTIFIC RESEARCH

UNESCO CONFERENCE

AN International Conference on Radioisotopes in Scientific Research arranged by Unesco was held in Paris during September 9–20. Some 1,200 scientists from sixty-one countries assembled in the Faculty of Medicine. This was the largest conference on isotopes ever held, and was very considerably bigger than the previous Isotope Conferences at Oxford in 1951 and 1954.

The impressive opening of the Conference took place at the nearby Sorbonne, where the president, Sir John Cockcroft, gave a short speech in which he stressed the importance of isotopes and said that, "What has been established already has shown the importance of radioisotope techniques in such wide and diverse fields that they rival nuclear power itself for their benefits to humanity". After the opening, except for two plenary sessions, all meetings were divided between the physical and biological sciences.

Physical Sciences Sessions

More than a hundred papers were read and discussed. They gave an astounding mass of information and showed the great progress which has been made since the last Geneva Conference two years ago.

In the sessions on production of isotopes, a paper was discussed dealing with the long-lived radioisotope aluminium-26, and its properties; a Russian paper dealt with new methods of depositing alpha-, beta-, and gamma-sources; French and British papers gave details of the extraction of the fission product cæsium-137, an isotope which will be used in the future for irradiation sources.

The session on the physics of metals dealt with diffusion problems, metal structure and grain-boundary diffusion. Radioisotopes have shown themselves to be the outstanding tool for development in this field. Research in industrial applications was represented by a theoretical paper on the measurement of fluid density, and by another in which outstanding results on flotation studies were presented.

Solid-state physics and physical chemistry in general were represented by many papers. Perhaps the most interesting were those describing research on structural defects in germanium monocrystals and the elegant emanation method used to give insight into the uranium oxide–zinc oxide and uranium oxide–titanium oxide systems. A number of papers dealt with exchange reactions of ions and complexes, and determination of the heat of sublimation and the diffusion of aqueous vapour. Radioactive gases were used for solid-surface measurements.

A number of interesting papers dealt with organic chemistry. One Russian paper threw new light on the mechanism of catalysis and a German paper dealt with the study of the Hoffmann degradation using tritium. An interesting session dealt with recoil chemistry; and the more general applications of Szilard–Chalmers reactions were described. A most interesting report was by Wolf (United States) on the use of recoiling carbon-14 in a new technique for labelling organic compounds. This technique recently developed may have big future applications in organic synthesis of carbon-14 compounds. Another American paper dealt with the recoil of tritium atoms on organic compounds, a process which also seems to have good preparative prospects.

In analytical chemistry emphasis was on gamma-ray spectrometry, a development which seems to have gone so far that in certain circumstances it can be relied upon entirely to the exclusion of chemical separations.

Two plenary sessions dealt with methods and techniques. A number of papers described progress in scintillation counting and counting methods. Two interesting British contributions were on the measurement of chromatograms, and on a technique for the simultaneous recording of the instantaneous counting rates of phosphorus-32 and iodine-131 in blood. An amusing application dealt with the use of oxygen-15, which has a half-life of 2·1 minutes, in relation to the tension in neoplasms. A number of papers dealt with improved methods of autoradiography, including a Russian contribution on an autoradiographical technique in which high pressure is applied to radioactive leaves which are between layers of filter paper.

Of outstanding interest were the two sessions on geophysics. The Japanese have studied antique relics by back-scattering methods. The sulphur-32–sulphur-34 ratio in meteorites has been investigated as well as the radioactivity induced by cosmic rays in meteorites and tektites. Dr. Libby read a paper which drew conclusions about the continental water-balance by measuring man-made tritium resulting from atomic bombs. This calculation, which was based on a number of assumptions, was nevertheless interesting in so far as it was possible for the first time to make any estimate at all of the continental water reservoir, especially in the Mississippi valley. It also gave estimates of the general rates of turnover of water.

The last day was devoted to isotope research in connexion with parity in physics, and a number of specialists, including Miss C. S. Wu, Dr. M. Deutsch and Dr. H. Halban, spoke on this problem.

A number of interesting films, including some from the United States, the U.S.S.R., Britain and France, were shown during the lunch intervals. They dealt with atomic reactors, isotope production and applications. Two private symposia were held, on the production of isotopes and on residual radioactivity in finished products. They were of great benefit as they allowed a free exchange of international opinion around a small conference table.

All the sessions on physics and chemistry had a very numerous and interested audience; this shows that chemists and physicists at least are not yet so specialized that they cannot follow scientific subjects other than their own with interest. It is to be hoped that such conferences will be repeated at two or three yearly intervals, for while they give an opportunity for people working in similar fields to meet, at the same time they may help to counteract the threat of over-specialization among scientists.

H. SELIGMAN

Biological Sciences Sessions

The Biological Sciences Sessions at the Unesco Conference on Radioisotopes in Scientific Research were planned on an ambitious scale to embrace all major fields of biological study in which isotopes are used, excepting only clinical diagnosis and the biological effects of radiation. More than a hundred papers were read at seventeen sessions embracing pharmacology; thyroid metabolism; lipid metabolism, blood and blood proteins; nucleic acids; protein and amino-acid metabolism; metabolism in brain and nervous system; carbohydrate metabolism; metabolism of fission products in soils, plants and mammals; nutrient assimilation in plants; translocation in plants; photosynthesis; plant biosynthesis; plant metabolism; and productivity of oceans and lakes. In addition, plenary sessions attended by both physical scientists and biologists were devoted to questions of technique, and a number of evening lectures of a more general nature were provided. Speakers from eighteen countries appeared on the programme. France, the host country, was the major contributor, but Belgium, the United Kingdom, the United States and the U.S.S.R. each provided ten or more papers. Other contributors came from Canada, Denmark, Germany, Ghana, India, Israel, Italy, Japan, the Netherlands, Poland, Roumania, Sweden and Yugoslavia.

The preparation of this programme was clearly a considerable task for the small panel of scientific consultants. Only a limited time was available for organizing the Conference, and it was necessary for them to consider not only the scientific quality of contributions but also the adequacy of the coverage of the subjects chosen, and the appropriate representation of different countries.

In terms of breadth of scope and international participation, Unesco achieved its objective. However, these requirements are difficult to reconcile with a uniformly high standard of scientific presentation. Moreover, the serious exchange of scientific ideas is easier when the subject of a conference is narrower and the interests of its participants are correspondingly closer. In the present Conference a further difficulty in the biological sessions was that, even at the best-attended lectures, the audience was lost in the spacious, it may be said magnificent, surroundings of the Grand Amphitheatre of the new Faculty of Medicine of the University of Paris. It is natural, therefore, that much of the most useful scientific discussion occurred in private. None the less, some sessions gave rise to most interesting discussions on the floor of the hall.

Abstracts of all papers presented have already been published (*International Journal of Applied Radiation and Isotopes*, 2, 175–264; 1957) and the Proceedings of the Conference are now in preparation; a detailed review is therefore inappropriate here and reference will be confined to general aspects.

A discussion in the session on lipid metabolism illustrated clearly the advantage which can occur when workers from widely differing fields are brought together. In a paper reporting work on lipids in the blood and milk of cows, reference was made to an as yet unidentified component in blood which had aroused interest by virtue of the high specific activity it rapidly attained in tracer studies. During subsequent discussion the possibility emerged that this component might well be diglycerophosphate, which had lately proved to be an important, though hitherto unidentified, metabolic intermediate in algae. It was most unfortunate that the division of the programme into 'animal' and 'plant' sessions caused the presentation of the paper on lipid synthesis in algae which dealt with this question to be deferred to a later session. Such examples of biochemical studies in plants providing interpretations of results obtained in animals are rare; new concepts developed in investigations with animals have more frequently aided the elucidation of biochemical problems arising in connexion with plants.

To many British and American representatives at the Conference the presence of a strong delegation from the U.S.S.R. was of particular interest. Russian contributions occupied the greater part of the session on the metabolism of the brain and the nervous system; the turnover of proteins and nucleoproteins, and the metabolism of glycogen were here major questions of interest. Russian contributions were also numerous in the session on plant biochemistry and photosynthesis.

One session was devoted to the metabolism of fission products in soils, plants and mammals. The major focus of interest was the relative behaviour of strontium and calcium throughout the biosphere. This question was discussed in relation both to the upward passage of the two ions from the roots to the shoots of plants and to their subsequent metabolism in the animal body. The extent to which strontium, and also iodine, are transferred to milk was also discussed.

A day was devoted to the assimilation and translocation of nutrients in plants. In contrast with contributions at many earlier conferences on the application of tracer methods to this field, the majority of the papers were concerned with detailed physiological questions, such as the factors controlling translocation and the nature of the flux of ions across the cytoplasm of cells. Large-scale field experiments with labelled fertilizers, which were at one time widely believed to hold considerable promise, received little consideration.

In several evening lectures the importance of the industrial applications of radioisotopes was emphasized. Spectacular achievements were reported in the reduction of production costs by the use of radioactive thickness gauges and other procedures. It was estimated that in the United States industry is already saving more than 300 million dollars a year. Agriculture, the world's greatest 'biological' industry, promises no comparable rapid economic gain. The opportunity, which radiation provides, of producing new varieties of plants by mutation was referred to on a number of occasions. However, the probable value of this procedure can easily be overrated. As a representative of the Food and Agriculture Organization of the United Nations stated: "One word of warning, however, is needed in this connexion. It should be remembered that few countries, developed or underdeveloped, have adequately exploited, in their plant breeding programmes, the breeding material already present in their native crops or in material that could easily be introduced from other parts of the world. It is important, therefore, especially in countries with a limited number of scientists, that plans for the use of radiation in plant breeding should not be at the expense of money and trained manpower needed for the basic fundamentals of an effective plant breeding programme conducted on a conventional basis." However, if the Conference held out no prospects of isotope procedures leading to immediate economic gain in the biological sphere comparable to that which may result from their application to the physical processes of industry, there was ample evidence that the eventual gain through research applied both to medical and agricultural questions may be at least as great.

This Conference may in some ways be regarded as the successor, though on a larger scale, to other isotope conferences, for example, those which the United Kingdom Atomic Energy Authority held at Oxford in 1951 and 1954. Apart from the lavish hospitality which the French Government and several embassies provided, the most striking aspect in which the Paris Conference differed from its predecessors was in a shift of emphasis from techniques to results. It is true that the sessions devoted to techniques were of considerable interest, particularly from the point of view of scintillation counting, very rapid sampling procedures in biological work, and autoradiograph procedures. Much information on these questions is, however, now readily available, and facilities for tracer work have become as much part of the normal equipment of many biological laboratories as the microscope. Past conferences on radioisotopes in research have greatly aided this development and the value of the Paris Conference is beyond doubt. However, it can legitimately be asked whether such gatherings have, by their success, made their continuation largely unnecessary for the experimental biologist. The majority of scientific conferences concerned with experimental biology to-day embrace some aspects of radioisotope research; in the future it will be increasingly so, and the successful use of tracer methods may in future be better stimulated by conferences convened to discuss more limited fields.

R. SCOTT RUSSELL

STATISTICS IN THE UNIVERSITY OF ABERDEEN

THE University of Aberdeen was among the first of British universities to provide for the teaching of statistics: in 1906, the Senatus recommended "the institution of a short course of lectures in the University on Statistical Methods which, in the opinion of the Senatus, is required for the equipment of advanced students in various branches of Science". In consequence of this recommendation, Mr. W. R. Macdonnell was "asked to act as lecturer, as he has given much attention to the subject and is competent to impart instruction in it". Macdonnell, who had been closely associated with Prof. Karl Pearson of University College, London, laid a firm foundation on which his successor, Dr. J. F. Tocher, was able to build more ambitiously. Tocher was one of the pioneers in the teaching of statistical methods and in the practice of statistical science; a well-known Aberdeen personality, about whom anecdotes are still current, he was lecturer during 1910–39. The University Calendar for 1920 shows that, even at this early date, Tocher was providing, single-handed, a breadth of statistical instruction that would not shame any university to-day: his lectures ranged over biometry, anthropometry, medical and vital statistics, eugenics and economic statistics, with strong emphasis on computing and practical work.

In 1954, the appointment of Dr. D. J. Finney as reader in statistics and the simultaneous establishment, within the Department, of the Agricultural Research Council's Unit of Statistics began a new phase of development. The resultant rapid increase in staff caused a degree of overcrowding that seriously impeded work. This period of discomfort has now ended: on October 7 Lord Cameron, chairman of the Carnegie Trust, inaugurated the new building that the Department now occupies. The building is a four-floor extension to the Chemistry Building in Old Aberdeen, Messrs. Pite, Son and Fairweather being the architects for both. The total cost, £32,000, has been met by generous assistance from the Carnegie Trust and the University Grants Committee and a deeply appreciated gift of £10,000 from the Rockefeller Foundation.

At present, the Department of Statistics has two floors of this building, giving an area of nearly five thousand square feet. There are individual rooms for each member of the teaching and research staff, two large rooms for a team of ten or twelve computers, two rooms for graduate students, and a classroom that accommodates up to twenty-four for practical work or more for lectures. The Department does not yet possess any large-scale computing machinery, but a room has been set aside for the eventual acquisition of electronic equipment. The accommodation must compare very favourably with that of any other university department of statistics in Britain.

The Department now has four lecturers and assistants, and the Unit of Statistics a further five graduate statisticians. A broad programme of elementary lectures enables undergraduate students in many different fields to obtain some knowledge of statistical principles; a particular feature of Aberdeen practice is the inclusion of about twenty hours of instruction in statistical science for medical students. Students of mathematics or economics can take statistics as a special subject for final honours. Aberdeen has followed several other British universities in instituting a diploma in statistics, based on postgraduate instruction, as a measure to combat the acute shortage of trained statisticians that most countries have experienced since 1945; teaching of the first students, a group of three from as far apart as Pakistan, South Africa and Wales, has just begun. In addition, there are facilities for Ph.D. students and, of particular value for those from overseas, a few students can be taken who have no degree or diploma in view but who wish to attend lectures and to gain experience of special types of statistical work.

For many years, the connexion of the Department with agricultural research has been close. The statistical sections of the Rowett Research Institute and the Macaulay Institute for Soil Research began as offshoots from the University Department; the North of Scotland College of Agriculture, situated in Aberdeen and closely associated with the University Department of Agriculture, has frequently sought assistance in the planning of field experiments and in the analysis of results. The new Unit of Statistics is intended to make a similar service available to agricultural research throughout Scotland. The aim is that any member of the staff of an agricultural college or research institute should be able to ask the Unit for statistical advice and even for computational help where special circumstances justify this. Not least important is the possibility that, through the provision of a unified statistical analysis, the Unit can encourage co-ordination of research and of reporting on related topics studied at different centres. At the suggestion of the Scottish Agricultural Improvement Council, the Unit has recently played a leading part in initiating a Survey of Fertilizer Practice in Scotland; this Survey, performed in collaboration with the three Agricultural Colleges and following closely a pattern that has been used with success in England and Wales, for the first time gives objective information on the types, quantities and methods of fertilizer application now used by Scottish farmers.

There is no rigid distinction between the staffs of the Department and the Unit. Members of the Unit undertake some teaching and members of the University staff may help with agricultural problems; the Department gives assistance to the science departments of the University in much the same way as the Unit does to other institutes. Inevitably, there is an agricultural bias in the teaching, and, of eleven graduate students who have worked in the Department since 1954, six have been on leave from employment in agricultural research. Efforts are now being made to strengthen activities of the Department in other fields, notably in mathematical statistics and in applications to research in medicine and social science. The staff of the Department is young, and most of its members have still to make their marks in research. Nevertheless, a number of very diverse topics in pure and applied statistics are at present under investigation. Among these are problems of vital statistics and population age structure, genetic equilibrium, statistical selection, demand curves and budget analysis, queue theory, comparison and calibration of milk testing techniques, design and analysis of animal feeding trials, and special aspects of experimental planning.

BUILDING RESEARCH, 1956*

THIS publication comprises the reports for the year 1956 of the Building Research Board and the Director of Building Research, Department of Scientific and Industrial Research. In its report the Board directs attention to the very great effort devoted by the Building Research Station to securing the application of the results of research in the building industry, but comments that this work, valuable though it is, cannot be extended at the expense of the longer term and more basic investigations in the Station's programme. The Board also notes with regret the further postponement of the construction of a new materials laboratory, originally planned for completion in 1951. This delay is particularly unfortunate if, as might be expected, lack of suitable accommodation is a further factor hampering the development of the more fundamental scientific work of the Station.

The Director's report outlines the very extensive and varied programme of research work in progress during the year under review; the topics investigated range from the hydration of cement to the design of a spray tap for ablution in offices. Without losing sight of the value of those topics of more immediate practical import, a few points of particular scientific interest may be mentioned.

For the study of the constitution of the principal chemical compounds produced at high temperatures in the manufacture of cements a microscope has been developed which permits the direct examination of the material at temperatures up to about 2,000° C. The specimen is held under the microscope at the tip of a thermocouple which when heated electrically also serves to fuse the material. The different compounds present can be identified and their melting range determined by direct observation. The instrument developed at the Building Research Station represents an advance on earlier apparatus of this kind because the method of fusing the specimen and the simplicity of its construction afford a degree of flexibility and accuracy not previously attained. The instrument has also been used at temperatures above 2,000° C. for the study of the system $2\,CaO.SiO_2$–$3\,CaO.P_2O_5$, which is of interest because of the adverse effect of phosphorus pentoxide on cement quality. Other studies in the field of cement chemistry have been concerned with the lime–alumina–water system by X-ray analysis and with the deterioration of high alumina cement which has attained a high temperature during setting or which has been afterwards stored under warm, moist conditions. The deterioration has been ascribed to the conversion of hydrated mono- or di-calcium aluminates to the tri-calcium compound with release of hydrated alumina. A number of interesting photographs demonstrate the disintegration of mortar cubes, in which the conversion had taken place, when immersed for 14 days in a solution of magnesium sulphate; this resulted from the reaction of the compound $3CaO.Al_2O_3.6H_2O$, formed during the 'conversion', with the sulphate ions to produce ettringite, $3CaO.Al_2O_3.3CaSO_4.32H_2O$. Normal high-alumina cement was unaffected by magnesium sulphate solution after immersion for as long as eighteen months.

An elusive problem is the assessment of the liability of building stones to deterioration on exposure to atmospheric conditions, but some progress is reported as a result of a further study of the pore structure in which the 'suction' of the material is correlated with its percentage saturation. Curves obtained by plotting suction against moisture content are indicative of the pore structure and enable differences in structure, which may or may not be appreciable under the microscope, to be expressed in quantitative terms. It is hoped that this work will make it possible to relate the pore-size distribution to the weathering properties of bricks and stone.

Rheological studies at the Building Research Station have been concerned with lime pastes, and a viscometer of the Couette type has been employed in this work. The difficulty resulting from the thixotropic nature of the materials under test is referred to, but in spite of this, reasonably consistent results appear to have been obtained with this apparatus.

An interesting application of centimetric electromagnetic radiation is described. This is a method for the determination of the total water content between the two faces of a wall. A narrow beam of 10 cm. radiation is directed normally through the wall, and for a variety of materials an approximately linear relationship is found to exist between the moisture content and the attenuation of the beam.

The provision of concrete shields for nuclear reactors presents a new and complex problem in the field of materials and structures which is being studied by the Building Research Station in collaboration with the U.K. Atomic Energy Authority. Instruments are being installed in the shield of the fourth reactor now under construction at Calder Hall for the measurement of strain, temperature, joint displacement and moisture. It is expected that the observations obtained will provide valuable data for future designs.

In the field of lighting, fundamental work is in progress in collaboration with the Medical Research Council on the problems of visual fatigue, attention and adaptation.

DULWICH COLLEGE

EXTENSION TO THE LABORATORIES

By R. GROVES

Master of the College

THERE can be few people now who are not convinced that the British public schools are aware of the country's need of scientific man-power. Not only is the teaching of science in these schools thoroughly 'respectable' now, but also the numbers specializing in science in the sixth forms are often more than 50 per cent of the total numbers in those forms, which is a sign that these schools realize the part that they have to play in meeting the need for scientists. The task now is to give every boy his chance to train as a scientist if he wishes, and this is more onerous than it was, for it means providing not only courses for the pure scientists, but also for those who will become technologists. It must be realized, too, that for every pure scientist we need many technologists, and for every technologist we need an army of technicians: all these have to be trained. Moreover, the sixth forms contain the classics, modern linguists and historians who, though perhaps numerically less, are still happily very strong, and it is to be hoped that they will continue to be so. It is surely essential, however, that an arts boy going up to the university must have some basic grounding in science, for he is going out eventually into a scientific world. Rather than being satisfied with a vague superficial approach to the subject, we have decided that every arts boy at Dulwich College shall do at least one physical science subject at General Certificate of Education Ordinary Level before going on to specialize in his own subject, thus attempting to give both depth and some idea of scientific method. All these considerations have led us during the past two years to do some hard thinking about the pattern of our scientific teaching, and have inevitably demanded more laboratories.

Perhaps the problem is more acute at Dulwich College, London, in that it is one of the few independent public schools which of its own volition takes a large proportion of its entrants from local authority scholars. This highly competitive entry gives it not only a remarkable cross-section of the population but also some able, fast-moving 'streams' from which many boys will go on to a university to read science or to an advanced technological institution to study applied science of some kind.

Fig. 2. New extension at the back of the Science Block opened on October 4

Historically, the development of this problem is interesting. Science at Dulwich was taught in the early part of the century by H. B. Baker under very primitive conditions, though much of his work on the drying of gases was done here. In 1907 Lord Rayleigh opened a new science block. At that time this must have been one of the best school science buildings in Britain, and even up to the Second World War it compared favourably with many others. It housed chemistry, physics and engineering, for which latter there was a well-equipped wood- and metal-work shop; biology was accommodated separately.

In the 1930's the sixth form numbered some 210, of which perhaps 20 per cent would be scientists. Just before the War this number began to increase, and has continued to do so since the War. The Rayleigh Block was largely destroyed by enemy action in 1944, and teaching had to be done partly in wooden huts and partly in the patched-up building. This continued through the post-war years, until the difficulties of scarcity of materials and money could be overcome, and finally in 1952 a new science block of nine laboratories, two lecture rooms and a library was opened (Fig. 1). This had been planned in 1947 when already some sixty boys were reading science for the General Certificate of Education (Advanced Level); but within a few years of its opening the number had increased to about two hundred; that is, those specializing in science after School Certificate, with one hundred taking the Advanced Level in any one year. This strained the accommodation considerably. The national call for more scientists, the demand within the school, coupled with the generous offer of help from the Industrial Fund for the Advancement of Science in Schools, spurred us on to extend—and to extend quickly. It is expected that with the increase in science teaching generally, by 1960 there will be 250 boys in the school specializing in science after reaching the Ordinary Level of the General Certificate of Education, and for these numbers we had to build our new extension.

This extension, though linked on to the previous block as the fourth long side to complete a quadrangle, has been built independently so as not to interfere with the working of the original laboratories. It gives five new laboratories, two for advanced and one for elementary chemistry, an advanced physics laboratory with ancillary electrical and dark rooms, together with a junior physics laboratory and a much-needed laboratory workshop. We also have two large lecture rooms which can become one, and thereby accommodate more than two hundred people to take advantage of the modern visual aids. Circulation space has been kept to a minimum, but offices have been provided for the senior chemistry and physics masters, and the usual balance rooms and preparation rooms have been included. Benches have been kept simple, but services to them ample; wooden block floor has been used, though economies have been made everywhere by leaving the brick bare in corridors and keeping decoration very plain. Sixth-form laboratories in particular have very good fume cupboards for chemistry, spaces available for leaving up apparatus when boys are attempting problems of a research nature, and the possibility of research to some extent, both by boys and masters, has been borne in mind in the whole plan.

The project was approved in July 1956, building was started almost immediately, the finished extension was ready for occupation in September 1957, and was officially opened on October 4 (Fig. 2). For this occasion the chairman, Lord Gorell, and the College governors entertained guests at the College Picture Gallery, at which Sir Harold Hartley, on behalf of the governors, thanked the Industrial Fund for the Advancement of Science in Schools, and Mr. John Oriel replied. In the new extension afterwards the Master of the College introduced Sir Cyril Hinshelwood, president of the Royal Society, who addressed the boys and declared the building officially open.

TIME-CORRELATED PHOTONS

By G. A. REBKA, JUN.,* and PROF. R. V. POUND
Lyman Laboratory of Physics, Harvard University, Cambridge, Massachusetts

SEVERAL studies of the time correlation of photons in coherent light beams have recently been reported in this journal[1–3]. We have undertaken to demonstrate such correlation using pulse and coincidence techniques in contrast to the continuous-wave technique used by Brown and Twiss in their first study. Our experiment differs from their more recent one[3] in that counts from each detector are recorded. These are used for reducing each observation to a measurement of effective resolving time.

Following the formulation of Purcell[4], the number of coincidences N_c in the counting period T can be written

$$N_c = (N_1 N_2/T)\{2\tau_R + np\alpha\tau_c f(\Delta)\}$$

The quantities N_1 and N_2 are the counts recorded from each detector, τ_R is the resolving time of the coincidence circuit, while τ_c is the correlation time of the light and is related to the width and shape of the spectral line used, in the manner discussed by Purcell. The factor n accounts for the presence of pulses of other origin than the light beam, which are assumed random. In our experiment a typical value of n was 0·951. Similarly p accounts for polarization of the light beam. It would have a value of $\frac{1}{2}$ for completely unpolarized light, and had a value of 0·45 in our optical system. The degree of geometrical coherence resulting from the arrangement of the optical system is described by α, which has a maximum value of 1 for complete coherence. With the assumption of uniform sensitivity over the small photocathode areas used, a value of 0·55 was calculated for our optical system. Finally, $f(\Delta)$, where the time Δ is the difference in delay between the two channels, depends, in our limit where $2\tau_R \gg \tau_c$, mainly on the properties of the coincidence circuit and detectors. These are such that $f(0) \approx 1$, and $f(|\Delta| > \tau_R) \approx 0$. Were it possible to achieve a system with $2\tau_R \ll \tau_c$, $f(\Delta)$ would represent the square of the cosine transform of the line shape of the light source.

Fig. 1 shows the arrangement of the optical system. A modified Baird–Atomic mercury-198 electrodeless discharge tube was driven by a 10-cm.-wave-length, continuous-wave magnetron delivering about 35 watts. Vapour from boiling nitrogen provided a coolant to prevent 'clean-up' of the mercury and to prevent broadening of the line in excess of Doppler effect[10]. Considerations of line width, intensity, and detector sensitivity led us to use the 4358-Å. line, which was separated with a Baird–Atomic interference filter. A phase-coherent beam was selected from the light passing through the hole, of diameter 0·02 cm., in B_1 by the hole of diameter 0·84 cm. in B_2. The baffle B_2 was 376 cm. distant from B_1. The baffle B_0 reduced reflexion from the walls housing the optical system. The dielectric mirror split the light into two beams, each of which was incident on the photocathode of an R.C.A. 6810 photomultiplier tube. Definition of the beam prior to the mirror in our system, in contrast to that of Brown and Twiss[1,3], assures geometrical coherence at the two detectors without critical adjustment. Consequently we were not able to vary the correlation by changing the geometrical coherence.

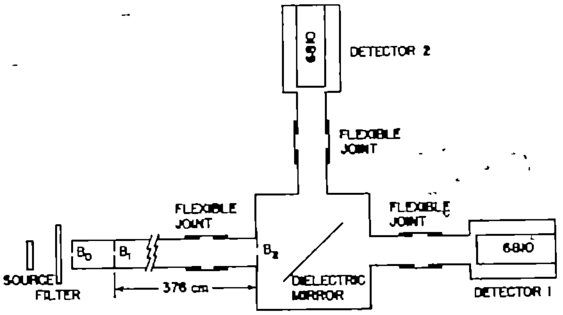

Fig. 1. A representation of the optical system. Baffles B_1 and B_2 define the geometrical coherence

The photomultiplier tubes were cooled throughout the experiment with solid carbon dioxide, and electrostatic shields at cathode potential were used to minimize dark current. The tubes were operated with an anode–cathode potential of 2,450 volts, and with the focusing grid and first dynode both 450 volts above the photocathode. Single photoelectrons produced an average pulse at the last dynode of 1/3 m.amp. and 15 × 10^{-9} sec. duration. Continuous application of the high voltage brought the dark current down after several days from an initially higher value to a steady state value equivalent to about 750 photoelectrons per second.

A block diagram of our electronic system is shown in Fig. 2. It represents a modification of the fast–slow system often used in coincidence spectrometry[11] in that the slow pulse-height-selecting channels were applied to the limited fast-channel pulses. Limitation of the counting speed set by the scalers and discriminators in the slow singles-channels made necessary paralysis of the limiter for a period of 4 × 10^{-6} sec. to eliminate coincidences between counts not resolvable in the slow channels. This resulted in a 25 per cent loss in the singles-channels for a typical counting rate of 4 × 10^4 counts per second. The minimum resolving time, which was limited by transit-time effects in the photomultipliers, was established by replacing B_2 by a light-pulse source composed of liquid scintillator and cobalt-60. The

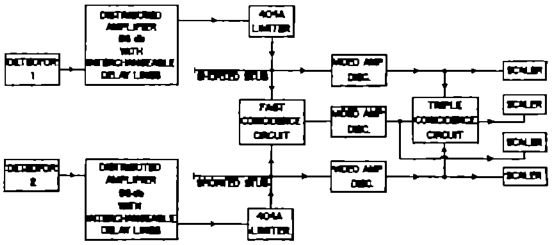

Fig. 2. Block diagram of the electronic system

intensity of each light pulse was such that few events detected from each photomultiplier corresponded to more than one photoelectron. With this source, a curve of coincidence counts versus time-delay difference indicated a coincidence efficiency corresponding to $f(0) > 0 \cdot 85$ for $\tau_R > 6 \times 10^{-9}$ sec.

---

* National Science Foundation Predoctoral Fellow.

With the parameters of the light source, optical system, and electronic system thus established, the correlated, relative to the random, coincidences were expected to be between 1 and 2 per cent. With the additional limitation in counting rate, at least 5 hr. of counting sample would be required to distinguish the correlation. By alternating the delay Δ between 0 and $6\tau_R$ every 100 sec., the effect of drift of the resolving time during this long counting period was minimized.

The combination of all measurements made with a resolving time of about 6×10^{-9} sec. yields

$$np \propto f(0)\tau_0 = (0 \cdot 173 \pm 0 \cdot 018) \times 10^{-9} \text{ sec.}$$

The error accounts only for the statistical accuracy of the sample. The experimental value of

$$\tau_0 = (0 \cdot 81 \pm 0 \cdot 16) \times 10^{-9} \text{ sec.}$$

is less accurately known since measurements and estimates of the other factors contribute to the uncertainty. For a line having a Doppler-broadened shape, this value of τ_0 would correspond to a full width at half height of 820 ± 160 Mc./s. The corresponding width for a mercury source at 300° K. would be 600 Mc./s.

Other measurements were made with a resolving time of about 9×10^{-9} sec., and these gave:

$$np \propto f(0)\tau_0 = (0 \cdot 214 \pm 0 \cdot 033) \times 10^{-9} \text{ sec.}$$

and

$$\tau_0 = (0 \cdot 90 \pm 0 \cdot 22) \times 10^{-9} \text{ sec.}$$

This result indicates that our estimates of the coincidence efficiency for $\tau_R = 6 \times 10^{-9}$ sec. are not significantly in error.

A check for any systematic error inherent in changing the delay was made by repeating the measurement with the light source replaced by a direct-current mercury arc which had a broad line. No significant effect was found within the statistical accuracy of the sample.

The authors wish to thank Prof. Francis Bitter, Mr. Adrian C. Melissinos, and the staff of the Research Laboratory of Electronics, Massachusetts Institute of Technology for the loan of their specially designed mercury-198 isotope lamp.

This work was supported in part by the joint programme of the Office of Naval Research and the U.S. Atomic Energy Commission.

INTERACTIONS OF CHLOROPHYLL IN ITS TRIPLET STATE WITH OXYGEN, CAROTENE, ETC.

By Dr. E. FUJIMORI and Prof. ROBERT LIVINGSTON
Department of Chemistry, University of Minnesota, Minneapolis

KINETIC and spectroscopic evidence[1,2] shows that the triplet (or possibly some other long-lived, energetic) state of chlorophyll is an essential intermediate in reactions sensitized by chlorophyll *in vitro*. It has been suggested[3] that the same state is involved in the photosynthesis of green plants. As a test of postulated mechanisms of the sensitized reactions, we have measured directly the half-life of the triplet state of chlorophyll, in organic solvents at ambient temperatures, in the presence and in the absence of oxygen, quinone, carotene, reductants, etc.

The solvents were of analytical reagent grade and were distilled, at least once, out of contact with air. Cyclo-octatetraene was distilled in a vacuum shortly before use. Quinone was purified by sublimation, and the reductants by fractional crystallization. The carotenes and xanthophyll were purified chromatographically on magnesium oxide columns. The chlorophylls were prepared and purified by Strain's modification of Zscheile's method[4]. The purity of the pigments was checked spectrophotometrically.

The solutions were de-aerated on a vacuum line. The stock of solvent was freed from dissolved gases by boiling off a substantial fraction at low temperature. The required sample of solvent was then transferred to the cuvette by low-temperature vacuum distillation. Known quantities of oxygen were sealed in capillaries which were placed in a side tube attached to the cuvette. After filling and re-evacuating the cuvette, the capillaries were broken and their content mixed with the solution.

The kinetic measurements were made with a flash-photolytic apparatus, provided with a single flash lamp and a scanning beam of constant intensity[5]. The scanning beam was rendered approximately monochromatic by means of one or more interference filters. After passing through the cuvette and filter, the beam fell on the sensitive surface of an R.C.A. 931*A* photomultiplier. The output of the multiplier was suitably amplified and fed to the *Y*-plates of a Techtronics 531 oscilloscope. The lamp was of 'Pyrex', 15 cm. long and filled with krypton at about 1 atm. The half-duration of the flash was approximately 10 μsec. The sweep of the oscilloscope was triggered when the lamp was fired. The resulting transient trace of the oscilloscope was recorded photographically. The sweep of the oscilloscope was linear within the limits of precision of the measure-

Table 1. HALF-LIVES OF THE TRIPLET STATE OF CHLOROPHYLL *a* IN BENZENE CONTAINING QUINONE

[Quinone] (*m.* × 10^{6})	$\tau_{1/2}$ (sec. × 10^{4})	$\tau_{1/2}^{-1}$ (sec.$^{-1}$ × 10^{-3})
0	4·05	2·47
2·5	3·00	3·33
5·0	2·67	3·75
7·5	1·65	6·06
15 0	1 58	6·33

ments. The times of sweep were checked with a high-frequency generator which had been calibrated with a standard crystal oscillator. The vertical displacement of the trace was proportional to the change in intensity of the light falling on the photomultiplier, within ± 3 per cent.

For transparent quenching reagents, a scanning beam having its maximum intensity at λ4775 A. was used. For quinone, the carotenes, etc., a scanning beam of λ5245 or 5720 A. was employed and the flash lamp was surrounded with an orange filter. This eliminated light which otherwise would have been, in part, absorbed by the quencher. The observed half-life for unquenched solutions was independent of the wave-length of the scanning beam. In the region λ4600–6000 A., the triplet absorbs more strongly than the singlet; therefore the transient corresponded to a temporary increase in absorption which decayed exponentially to its initial value.

Light from an unfiltered flash excited 70 per cent or more of the chlorophyll molecules to their triplet state; orange filters reduced this conversion to about 20 per cent. Since the scanning light was approximately monochromatic and the absorption curves comparatively flat, Beer's law can be used in the analysis of the data without introducing an appreciable error.

$$\frac{1}{l}\log J/I = \alpha_1(m - x) + \alpha_2 x$$

where l is the length of the cuvette, α_1 and α_2 the extinction coefficients of the singlet and triplet, respectively, x the concentration of the triplet and m the total or stoichiometric concentration of the chlorophyll. I is the intensity of the light reaching the photomultiplier after passing through the solution and J is the intensity corresponding to a cuvette filled with the solvent. Introducing I_∞, the intensity corresponding to a solution in which the chlorophyll is in the ground-state, we may write:

$$x = \frac{1}{l(\alpha_2 - \alpha_1)}\log\frac{I_\infty}{I}$$

For a first-order reaction,

$$\ln\frac{x_0}{x} = \ln\frac{\log I_\infty/I_0}{\log I_\infty/I} = \frac{\ln 2}{\tau_{1/2}}t$$

where x_0 and I_0 are the values of x and I at $t = 0$ and $\tau_{1/2}$ is the half time of the reaction. More careful analysis of the data (ref. 2, and private communication from H. Linschitz) indicates that the process is not strictly first-order but conforms to the following equation:

$$-\frac{dx}{dt} = (k_1 + k_2 x + k_3(m - x) + k_Q[Q])x$$

where k_2 and k_3 are approximately 10^{9} and 10^{7} *m.*$^{-1}$ sec.$^{-1}$, respectively. However, for the chlorophyll concentrations (about 1·5 × 10^{-6} *m.*) used in these experiments, values of k_Q (the bimolecular quenching constant) obtained from this relation do not differ significantly from those derived from an assumed first-order law. The values listed in Table 2 were obtained graphically by plotting the reciprocal of the observed half-life against the concentration of the quenching agent:

$$\ln 2/\tau_{1/2} = k^{0} + k^{Q}[Q]$$

Table 1 lists the half-lives observed for 1·5 × 10^{-6} *m.* solutions of chlorophyll *a* in benzene, containing *p*-benzoquinone at the concentrations indicated, and Table 2 summarizes the results obtained with effective quenchers.

In addition to the compounds listed in Table 2, phenylhydrazine, ethyl-*n*-phenyl carbamate, *m*-dinitrobenzene and triphenyltetrazolium chloride were tested in methanol, and ascorbic acid and allylthiourea were tested in pyridine. At concentrations of 10^{-3} *m.* (and of 10^{-1} *m.* for allylthiourea, ascorbic acid and phenylhydrazine) none of these substances noticeably affected the rate of disappearance of the chlorophyll triplet.

Kinetic studies[1,3] of chlorophyll-sensitized autoxidations indicate that the sensitizer in its triplet state reacts with a molecule of either oxygen or the reductant to form a short-lived intermediate, which in turn interacts with the other reactant to yield the final product. Since oxygen quenches the triplet state and the reducing agents do not, the mechanism involving the direct interaction of sensitizer triplet and the reductant is eliminated. It is, therefore, very probable that a short-lived, reactive 'moleoxide' of the sensitizer is an essential intermediate in such reactions[1,5,6]. The bimolecular rate-constants for quinone, β-carotene, α-carotene and xanthophyll are all in the range 1·0–1·6 × 10^{9} *m.*$^{-1}$ sec.$^{-1}$, which is about tenfold smaller than the maximum rate-constant of a diffusionally limited bimolecular reaction[7].

Since oxygen and quinone efficiently quench both the triplet and the fluorescent states and ascorbic acid quenches neither, further parallelism between the reactions of these two types of excited states might be expected. However, it does not appear to exist. Triphenyltetrazolium chloride and *m*-dinitrobenzene strongly quench the fluorescence of chlorophyll solutions but do not appreciably alter the half-life of the triplet state.

Table 2. SUMMARY OF QUENCHING CONSTANTS FOR THE TRIPLET STATE OF CHLOROPHYLL *a*

Quencher	Solvent	Range of concentrations	No. of independent measurements	k_Q, *m.*$^{-1}$ sec.$^{-1}$ × 10^{-9}
Quinone	Benzene	(15–2·5) × 10^{-7}	5	2 4 ± 0 5
Oxygen	Benzene	(3·6–1·1) × 10^{-6}	4	1·1 ± 0 3
β-Carotene	Benzene	(3·7–0·6) × 10^{-6}	5	1·3 ± 0·3
β-Carotene*	Benzene	(9·8–2·4) × 10^{-7}	5	1·5 ± 0·2
β-Carotene	Pyridine	1·2 × 10^{-6}	2	1 0 ± 0·4
α-Carotene	Benzene	(8·3–2 8) × 10^{-7}	5	1 6 ± 0·3
Luteol	Benzene	(9 0–4·5) × 10^{-7}	3	0·6 ± 0·3
Zea xanthophyll	Benzene	1 4 × 10^{-6}	2	0·7 ± 0·4
Cyclo-octatetraene	Methanol	(3 0–0·1) × 10^{-3}	5	0·0012 ± 0·0002

* Chlorophyll *b* was used in these measurements

Furthermore, β-carotene, which quenches the triplet as strongly as does oxygen, has no noticeable effect upon the amount of fluorescence of chlorophyll *b*.

Schenck has interpreted[8] the results of his extensive studies of dye- and pigment-sensitized oxidations as indicating that quinone is an efficient quencher of the triplet states of sensitizers and that cyclo-octatetraene is a moderately efficient quencher. At least for the case of chlorophyll, both these conclusions are fully confirmed by the present direct measurements.

The universal occurrence of carotene in all autotrophic plants has led to the speculation that it must play an important, if as yet unknown, part in photosynthesis. Recently[9] it has been demonstrated that the Hill reaction is inhibited if the carotene (but not the chlorophyll) is extracted from a chloroplast preparation. The addition of a solution of β-carotene to the extracted chloroplasts restored their ability to undergo the Hill reaction. In view of this information, it appeared to be worth while to test the carotenes for possible interactions with the triplet state of chlorophyll. As is demonstrated by the data of Table 2, β-carotene, α-carotene and xanthophyll are as efficient as oxygen in quenching the triplet state of chlorophyll *a*. Measurements with β-carotene and chlorophyll *b* demonstrate that the effect is not limited to chlorophyll *a*. While it still remains an unconfirmed speculation, the postulate that carotene plays a direct part in the primary act of photosynthesis gains support from the present results.

This investigation was supported by the United States Air Force through the Air Force Office of Scientific Research of the Air Research and Development Command under contract No. 18(600)-1485. We also wish to acknowledge the valuable assistance of Dr. D. Tanner, who constructed and tested the flash-photolytic apparatus.

SPECIFIC INHIBITION STUDIES RELATING TO THE LEWIS BLOOD-GROUP SYSTEM

By Dr. WINIFRED M. WATKINS and Prof. W. T. J. MORGAN, F.R.S.

Lister Institute of Preventive Medicine, London, S.W.1

One of the problems of outstanding interest to the biochemist working in the field of human blood groups is the elucidation of the chemical structures which are responsible for the complete serological independence of the various blood-group characters. Water-soluble substances showing *A*, *B*, *H* or Le^a blood-group specificity which have been isolated in an essentially homogeneous condition have been found to be qualitatively identical in composition[1]. Thus each contains the same four sugars, L-fucose, D-galactose, *N*-acetylglucosamine, and *N*-acetylgalactosamine, and at least eleven amino-acids. Certain quantitative differences in the proportions of the various sugars are fairly consistently observed in substances belonging to different groups, and these variations may be related to specificity differences[2]. The clearest indications available at present, however, concerning the components which play an important part in the specificity of the blood-group mucopolysaccharides have been obtained by studies of serological and enzyme inhibition reactions with simple sugars and derivatives of known structure.

The first indication that one of the component sugars of human *H* substance is more closely involved than the others in specificity was obtained when it was found that L-fucose inhibited the agglutination of O cells by an eel anti-*H* serum[3]. Examination of the inhibiting capacity of the methyl L-fuco-pyranosides and -furanosides showed that an α-L-fucopyranosyl structure gave the closest fit with the eel antibody although the inhibition was small compared with that given by intact *H* substance. Subsequent experiments with an anti-*H* reagent of plant origin, namely, an extract of *Lotus tetragonolobus* seeds, again indicated a specific role for an α-L-fucopyranosyl structure in *H* specificity[4]. Inhibition of the agglutination of *A* cells by plant seed anti-*A* reagents similarly pointed to the important part played by *N*-acetyl-D-galactosamine in *A* specificity[4]. This observation has been confirmed by quantitative inhibition of the precipitin reaction using human anti-*A* serum; by means of this technique it was also shown that an α-D-galactoside structure inhibited the *B*–anti-*B* system[5].

Independent evidence for the part played by L-fucose, *N*-acetyl-D-galactosamine and D-galactose in *H*, *A* and *B* specificity, respectively, was obtained through enzyme inhibition experiments, in which it was found that the enzymic hydrolysis of each blood-group substance was inhibited specifically by the sugar that had been shown by the serological inhibition tests to be involved in specificity[6]. The enzyme preparations used for the inactivation of the *A*, *B* and *H* substances were obtained from *Trichomonas foetus*[7]. Extracts from this organism also destroy the serological activity of the Lewis Le^a substance[8], the mucopolysaccharide material which is found in the secretions of individuals who do not secrete water-soluble *A*, *B* or *H* substances. Application of the enzyme inhibition technique to the Le^a system disclosed that the inactivation of Le^a substance could also be inhibited by L-fucose. At first sight this observation might suggest a relationship between *H* and Le^a specificity; serologically, however, these two substances are quite distinct and it is therefore probable that other structural differences, such as the mode of linkage of L-fucose, or the nature of the sugars adjacent to it, exist between *H* and Le^a substances. The enzyme inhibition results made it of considerable interest to know whether any known structures containing fucose would inhibit the reaction between *Le*(*a*+) red cells and anti-Le^a serum. Until recently, oligosaccharides containing L-fucose associated with galactose and/or amino-sugars were not known, but as a result of Prof. R. Kuhn's outstanding researches on the nature of the oligosaccharides in human milk which contain L-fucose, a number of these materials have now been described. At our request, Prof. R. Kuhn very kindly sent us samples of these oligosaccharides together with a seventh compound, isolated from human milk, lacto-*N*-tetraose, which does not contain fucose. The trivial names and constitutions of the compounds are as shown above.

(1) Lacto-*N*-tetraose[9]
β-D-galactosyl-(1 → 3)-β-D-*N*-acetylglucosaminoyl-(1 → 3)-β-D-galactosyl-(1 → 4)-D-glucose

(2) Lacto-*N*-fucopentaose I[10]
β-D-galactosyl-(1 → 3)-β-D-*N*-acetylglucosaminoyl-(1 → 3)-β-D-galactosyl-(1 → 4)-D-glucose
| (1 → 2)
α-L-fucosyl

(3) Lacto-*N*-fucopentaose II[11]
β-D-galactosyl-(1 → 3)-β-D-*N*-acetylglucosaminoyl-(1 → 3)-β-D-galactosyl-(1 → 4)-D-glucose
| (1 → 4)
α-L-fucosyl

(4) Lacto-*N*-difucohexaose
β-D-galactosyl-(1 → 3)-β-D-*N*-acetylglucosaminoyl-(1 → 3)-β-D-galactosyl-(1 → 4)-D-glucose
| (1 → 2) | (1 → 4)
α-L-fucosyl α-L-fucosyl

(5) Fucosido-lactose[12]
β-D-galactosyl-(1 → 4)-D-glucose
| (1 → 2)
α-L-fucosyl

(6) Fucosido-galactose[11]
α-L-fucosyl-(1 → 2)-D-galactose

(7) Lacto-difucotetraose[11]
β-D-galactosyl-(1 → 4)-D-glucose
| (1 → 2) | (1 → 3)
α-L-fucosyl α-L-fucosyl

A sample of lacto-*N*-fucopentait II, in which the terminal glucose in lacto-*N*-fucopentaose II had been reduced to sorbitol, was also supplied by Prof. Kuhn. Another fucose-containing disaccharide has been isolated from fucoidin by our colleague, Dr. R. Côté, and was available for study; the constitution of the compound has been established as α-L-fucosyl-(1 → 2)-L-fucose; the fucose present in this disaccharide and in all the sugars in the oligosaccharides from milk are believed to be in the pyranose form.

Kuhn and Osman[13] had tested oligosaccharides (1) to (5) for their capacity to inhibit the agglutination of O cells by eel serum and found that with the exception of fucosido-lactose, which showed slight inhibition, the compounds were without activity in this system in spite of the fact that out of the five tested four contained α-L-fucopyranosyl structures.

In our experiments the method used for testing the materials for their action on the Le^a system was that of inhibition of agglutination of *Le*(*a*+) red cells by a human anti-Le^a serum. In many instances the materials were also examined by means of inhibition of hæmolysis of ficin-treated *Le*(*a*+) cells, using a human anti-Le^a serum[14]. Hæmolysis and precipitin inhibition tests were also carried out with rabbit anti-Le^a reagents induced by an artificial antigen made by combining Le^a-substance with the conjugated protein component of the somatic *O* antigen of *Shigella dysenteriae*[15]. The following simple sugars failed to inhibit in the agglutination inhibition tests at a concentration of 1 per cent: D-glucose, D-arabinose, L-rhamnose, D-xylose, D-fructose, L-fucodesose, methyl α- and β-D-galactopyranosides, methyl α- and β-L-fucopyranosides, methyl α-L-fucofuranoside, methyl α- and β-*N*-acetyl-D-glucosaminides, methyl 2-*O*-methyl-L-fucopyranoside, β-D-(1 → 3)-, β-D-(1 → 4)- and β-D-(1 → 6)-galactopyranosyl-*N*-acetyl-D-glucosamine, melibiose, cellobiose, laminaribiose and raffinose.

The results of the agglutination inhibition tests with the oligosaccharides are given in Table 1. It will be seen that one compound, lacto-*N*-fucopentaose II, showed considerable activity, and a second compound, lacto-*N*-difucohexaose, weak but definite power to inhibit. Lacto-*N*-fucopentaose I, lacto-*N*-tetraose, lacto-difucotetraose, fucosido-lactose, α-L-fucosyl-(1 → 2)-galactose, α-L-fucosyl-(1 → 2)-fucose, and D- and L-fucose were inactive. Similar results were obtained in hæmolysis inhibition tests with human or rabbit anti-Le^a serum, and in precipitin inhibition tests in which a precipitating rabbit anti-Le^a serum was used. Hæmolysis and precipitin inhibition tests were, however, not carried out on all the substances examined in the agglutination inhibition tests. The failure of lacto-*N*-tetraose to inhibit supports the suggestion that L-fucose is an important part of the determinant specificity of Le^a-substance, since the tetraose differs from the strongly active lacto-*N*-fucopentaose II only in that the latter contains an α-L-fucosyl radical joined as a branching unit by a (1 → 4) linkage to *N*-acetyl-D-glucosamine. When the fucose is joined by a (1 → 2) linkage to a galactose as in lacto-*N*-fucopentaose I, fucosido-lactose, or α-fucosyl-(1 → 2)-galactose, the substances possess no activity and it is evident that the specificity requirements of the Le^a antibody cannot be fulfilled. The proximity of a second fucose molecule joined to

Table 1. THE AMOUNTS OF Le^a SUBSTANCE AND SUGARS GIVING INHIBITION WITH HUMAN ANTI-Le^a SERUM

Substance	Minimum amount of substance giving inhibition* (μgm./0·1 ml.)
Human Le^a substance	0·04
L-Fucose	> 1,000
D-Fucose	> 1,000
α-Fucosyl-(1 → 2)-fucose	> 1,000
α-Fucosyl-(1 → 2)-galactose	> 1,000
Fucosido-lactose	> 1,000
Lacto-*N*-tetraose	> 1,000
Lacto-difucotetraose	> 1,000
Lacto-*N*-fucopentaose I	> 1,000
Lacto-*N*-fucopentaose II	1
Lacto-*N*-fucopentait II	1
Lacto-*N*-difucohexaose	60

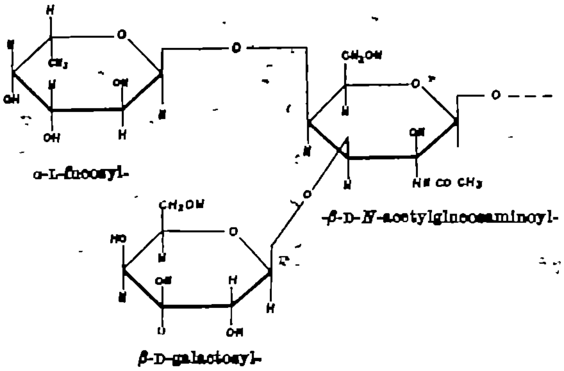
* Equal volume of inhibitor added to volume of anti-Le^a serum

galactose, as in lacto-*N*-difucohexaose, appears to impair the specific relationship, since the hexasaccharide is a much weaker inhibitor than is lacto-fucopentaose II. The observation that the inhibiting power of lacto-*N*-fucopentaose II is unimpaired when the terminal glucose is reduced to sorbitol, as in lacto-*N*-fucopentaitol II, supports the belief that glucose, which is absent from *Le*ᵃ substance, plays no part in the specific inhibition shown by the pentaose. Treatment of lacto-*N*-fucopentaose II with a crude *T. foetus* enzyme preparation destroyed its capacity to inhibit in the *Le*ᵃ system; chromatographic examination of the enzyme-treated material showed that the pentaose had been completely broken down into its component sugars.

It is known that the *ABH* blood-group mucopolysaccharides occur in human milk[16] and the closely similar *Le*ᵃ substance will most probably also be present, especially in the milk of *Le*(*a*+) women. The possibility that the lacto-*N*-fucopentaose II was contaminated with traces of highly active *Le*ᵃ substance had therefore to be considered. To test this possibility, 10 mgm. of lacto-*N*-fucopentaose II were dialysed through a 'Visking' membrane and recovered. The whole of the activity readily diffused and could therefore not be due to *Le*ᵃ substance, which is known to be indiffusible through 'Visking' membranes. Additional evidence to support this conclusion is obtained from the fact that the closely similar lacto-*N*-fucopentaose I which is isolated from milk by the same technique as is lacto-*N*-fucopentaose II is nevertheless inactive in the *Le*ᵃ test.

Preliminary observations on the inhibition by simple carbohydrates of the agglutination of *Le*(*b*+) cells by human anti-*Le*ᵇ serum[17] showed that, of the fucose-containing oligosaccharides, lacto-*N*-difucohexaose, and lacto-difucotetraose were the only two which gave definite but weak inhibition. The significance of these observations must await further work on this system, but a possible interpretation is that two fucose residues, arranged spatially as in these compounds, are concerned in *Le*ᵇ specificity.

In conclusion, the results of the serological inhibition tests indicate that an α-L-fucopyranosyl structure is concerned in *Le*ᵃ specificity and that two such units are possibly involved in *Le*ᵇ specificity. The α-L-fucosyl structure alone, however, is unable to neutralize the *Le*ᵃ antibody, as is demonstrated by the inactivity of methyl α-L-fucopyranoside, α-fucosyl(1 → 2)-fucose, the oligosaccharides (2, 5, 6 and 7) containing fucose joined by a (1 → 2) linkage to galactose and lacto-difucotetraose, which contains, in addition, an α-fucosyl residue joined by a (1 → 3) linkage to glucose. An α-L-fucose unit joined by a (1 → 4) glycosidic linkage to *N*-acetyl-D-glucosamine, as in lacto-*N*-fucopentaose II, is compatible with a high degree of inhibition, and it would appear, therefore, that this structural unit is an important requirement for the neutralization of *Le*ᵃ antibody. The second oligosaccharide in the series tested which contains this unit, lacto-*N*-difucohexaose, is, however, a much poorer inhibitor than is lacto-*N*-fucopentaose II. This could be due to the steric hindrance of the L-fucose joined to the non-reducing galactosyl end-unit of the lacto-*N*-tetraose backbone whereby the antibody is unable to approach closely enough to make a firm combination with the specific grouping. Alternatively, one could speculate that the activity of the pentaose II resides in the specific spatial pattern given by the structure:



and that a branched trisaccharide unit formed by two non-reducing end-units, α-L-fucosyl- and β-D-galactosyl, attached to *N*-acetyl-D-glucosamine functions as the specific determinant grouping in *Le*ᵃ serological reactions. It should be borne in mind, however, that the structure present in lacto-*N*-fucopentaose II probably corresponds only in part to the specific configuration present in *Le*ᵃ substance, because the inhibition given by the pentasaccharide is only a fraction of that given by the homologous substance. Serologically active oligosaccharides containing fucose, galactose and amino sugar have been isolated from *Le*ᵃ substance by partial hydrolysis at 100° with barium carbonate (pH 8·5)[18], and it is hoped that work now in progress will provide direct evidence for the nature of the dominant serological structures responsible for *Le*ᵃ specificity.

We wish to thank Prof. R. Kuhn for the oligosaccharides from human milk, without which this investigation would not have been possible, and Dr. J. Lundevall, Oslo, for a generous supply of human anti-*Le*ᵃ serum. These studies were aided by a grant from the Nuffield Trust.

Note. This communication was first submitted to *Nature* and accepted for publication in October 1956; it was afterwards withdrawn by the authors because Prof. Kuhn wished to obtain further proof for the structures earlier suggested for pentaoses I and II. The original structure for pentaose II was found to be correct and the main conclusions reached by the authors at that time have therefore remained essentially unchanged. A number of small observations made during the past few months have been added.

Examination of the Oligosaccharides isolated from Jute α-Cellulose

In a previous communication[1], it has been shown that a number of sugar residues, in addition to those reported earlier[2,3], can be identified in jute α-cellulose on modifying both the conventional hydrolytic procedure and the technique of developing the chromatogram. The nature of association among the various sugar components in jute cellulose has not so far been established, however. Das *et al.*[2] claim to have isolated an oligosaccharide containing glucose, xylose and arabinose from the hydrolysate of jute α-cellulose with formic acid, whereas Adams and Bishop[3] have failed to substantiate this result. The work now briefly described deals with the isolation of oligosaccharides from the incomplete hydrolytic products of jute α-cellulose after a mild treatment with sulphuric acid, and has the object of elucidating the mode of association of the different sugar components with the glucose unit of the cellulose chain.

α-Cellulose (10 gm.) employed in this work was prepared by the action of 9·5 per cent caustic soda on chlorite holocellulose obtained from *tossa* jute and partially hydrolysed with *N*/2 sulphuric acid (200 ml.) for 1 hr. at 98°–99° C., when 3 per cent of the material went into solution. The extract, after direct neutralization with barium carbonate, was chromatographed on Whatman No. 1 filter paper as described earlier[1]. The chromatogram thus obtained showed the presence of all the sugar components, with the exception of barium uronate, previously reported[1], along with ten spots of oligosaccharides, either pink or yellow in colour and occurring between the starting line and the position of uronate.

A pentose can readily be differentiated by its characteristic pink colour from a hexose, which yields a yellow to brown colour, but the faint yellow colour of the outer zone of a spot and that arising from a substance occurring in trace amounts, are extremely difficult to distinguish with the naked eye. Under ultra-violet light, however, the faint yellow colour becomes distinctly visible due to a greenish-yellow fluorescence. The outlines of spots of oligosaccharides, particularly those of yellow colour, were therefore obtained on examination under ultra-violet light, because under this condition fluorescence similar to that of a simple hexose residue was exhibited by an oligosaccharide. The portion of the chromatogram containing the oligosaccharides is represented by Fig. 1.

Of the various oligosaccharides obtained, those corresponding to spots 1, 6, 8 and 10 were isolated after separation on Whatman No. 3*MM* filter paper, the former two spots being yellow and the latter two pink in colour. The individual oligosaccharides, which yielded single spots on being separately chromatographed, were completely hydrolysed with boiling *N* sulphuric acid and the component sugars chromatographically identified. Although the oligosaccharides corresponding to spots 1 and 8 give rise to different colours and are of widely different R_F values, the constituent sugars of both these substances are found to be galactose, glucose and xylose with traces of mannose. The spot of the last sugar is, however, so faint, particularly when derived from spot 8, that it becomes detectable only under ultra-violet light. The oligosaccharide of spot 6 is composed of galactose, glucose and xylose, while that obtained from spot 10 consists of glucose and xylose possibly with traces of mannose.

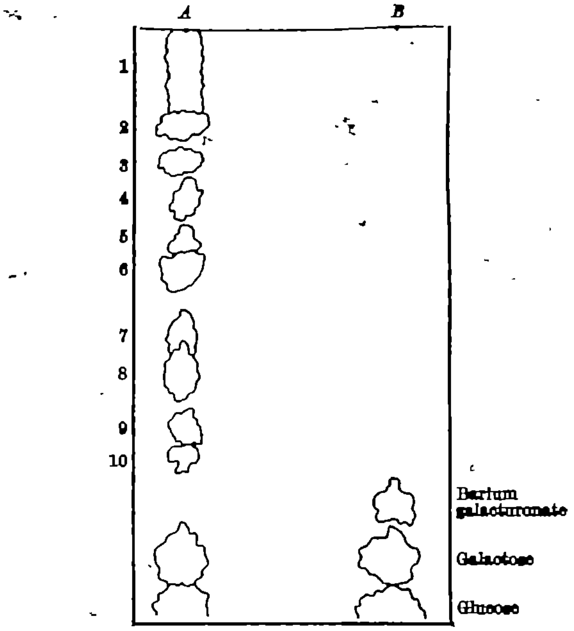

Fig. 1. Chromatogram with *n*-butanol–acetic acid–water (1 : 0·24 : 1), using aniline hydrogen phthalate as a spraying agent. *A*, jute α-cellulose hydrolysate; *B*, reference sugars. Of the oligosaccharide spots 2, 5, 8 and 10 were pink and the rest yellow to brown in colour

Since glucose has been found to be one of the main components of the oligosaccharides studied, the above results seem to offer a direct evidence of the chemical association of galactose, xylose and possibly mannose with the glucose residues of jute α-cellulose. Since it has been noticed that most of the arabinose and rhamnose components are hydrolysed by the action of *N*/2 sulphuric acid, the chemical linkage, if any, between these two sugars and cellulose, appears to be readily broken.

Vitamin B_{12} in Marine Ecology

At least half the marine algal flagellates and diatoms which have been studied in pure culture have been shown[1] to require an exogenous source of vitamin B_{12}, which is the reason for an interest in the occurrence of this vitamin in the sea as one of the factors controlling phytoplankton populations and the productivity of water masses. However, the amount of vitamin required is very small; just how small is not generally realized, and it may be that the amount found in the sea is never sufficiently low for an ecological control to be exerted on any of the comparatively very sparse populations of phytoplankton which happen to require the vitamin. Whether, in fact, this is so cannot be decided directly with natural populations for a number of reasons, but it has been possible to determine the magnitude of the requirement of vitamin B_{12} in one marine organism and then, assuming algae requiring vitamin B_{12} to be alike in this respect, to apply the result to data on marine populations and to assays of sea water for vitamin B_{12}.

Curves for *Monochrysis lutheri*, a euryhaline chrysomonad, suggested a linear relation between dosage of vitamin B_{12} and cell number, but the available data (Fig. 1, small circles) were based on computations from previously published optical measurements of growth[2,3]. Moreover, they did not extend to a level likely to be of ecological interest, so that some extrapolation was necessary. However, when rather greater care was taken in the preparation of the culture medium and inoculum and growth assessed directly by hæmocytometer counts it was possible to extend the range to 0·1 μμgm./ml., the lowest figure yet recorded in the sea[4] (Fig. 1, large open circles). In deriving the three curves in Fig. 1, it was necessary to correct each for carry-over before performing the logarithmic transformations. This was because the amount of vitamin B_{12} in any culture is the sum of what is added intentionally and what is introduced as carry-over (including also contamination from water, glassware and chemicals). The size of the correction to be applied to the dosage scale in each case was ascertained by a short extrapolation to the abscissa of the regression of cell numbers on dosage of vitamin B_{12}. It was, respectively, for the 1954 experiment 1·6 μμgm./ml., for the 1955 experiment 0·4 μμgm./ml. and for the 1957 experiment 0·05 μμgm./ml.

The 1957 experiment agrees well with the previous ones; all the points lie about a straight line with a slope of unity on logarithmic co-ordinates, thus indicating a linear relation between cell numbers and concentration of vitamin B_{12}, at least between the limits 0·1 and 10 μμgm./ml. Between these limits each μμgm. supports 800,000 cells of *Monochrysis*, that is, about 540 molecules per cell, or reckoning 200 μ^3 as the mean size of *Monochrysis*, 3 molecules per μ^3 of living alga. By way of comparison, *Euglena gracilis* (2,000 μ^3) requires 4,900 molecules per cell[5] and *Stichococcus* sp. (12 μ^3) 40 molecules[6], which are requirements of the same order of magnitude as that of *Monochrysis*.

Vitamin B_{12} has been measured in the sea on several occasions. Applying the *Monochrysis* data to Cowey's measurements[4], the summer waters of the North Atlantic or northern North Sea (0·1 μμgm./ml.) contain sufficient vitamin B_{12} for at least 80,000 cells of *Monochrysis* per ml.; also from the same source, for the northern North Sea in autumn (0·5–1·0 μμgm./ml.) up to 800,000 cells and the Butt of Lewis in spring (1·0–2·0 μμgm./ml.) up to 1,600,000 cells, and from Lewin[6] and Droop[3] for inshore waters (5–10 μμgm./ml.) up to 8,000,000 cells.

References to the size of phytoplankton crops are numerous in the literature[7]; those of the diatom *Skeletonema costatum* can be compared directly with the *Monochrysis* estimates since the two species are much of a size. In the Clyde area, where the spring bloom is *Skeletonema*, maxima of less than 2,000 cells per ml. occur in poor years, while in good years up to 10,000 cells may be recorded, the highest records being of the order of 25,000 cells (Dr. S. M. Marshall, personal communication). According to my reckoning, it would require less than 0·1 μμgm. of vitamin B_{12} (Cowey's lowest figure) to achieve a crop of 25,000 cells. Even when the relative sizes of the species are taken into account, the only instances quoted by Bainbridge[7] of populations which would require more than 0·1 μμgm. vitamin B_{12}/ml. are those of the Florida red tides. 60,000 cells per ml. of *Gymnodinium brevis*, the highest record[8], would require at most 3 μμgm. vitamin B_{12}/ml. (a *Gymnodinium* cell occupies[9] 7,500 μ^3, which is equivalent to 40 *Monochrysis* cells). Even so it is questionable whether coastal waters often contain less than this amount of the vitamin.

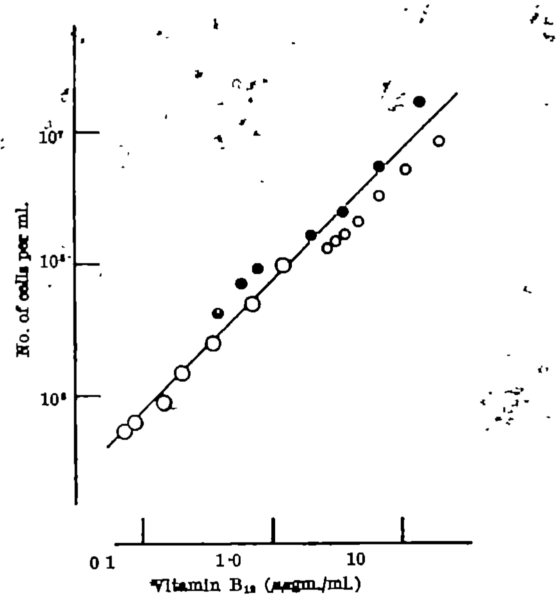

Fig. 1. Response of *Monochrysis lutheri* to vitamin B_{12}. Small open circles, 1954 experiment (ref. 2); small closed circles, 1955 experiment (ref. 3); large open circles, 1957 experiment

In short, with this possible exception of the red tides, the data available at present point to there being at all times more than sufficient vitamin B_{12} in the sea for the crops which are encountered.

IN the accompanying communication, Droop gives a calculation to demonstrate that vitamin B_{12} is present in the sea in amounts more than sufficient for the known plankton crops. It might be inferred from it that vitamin B_{12} is not a factor which influences the amounts and types of life present in the sea. There probably are, however, several modifying circumstances of which Droop, because of the incompleteness of available information, could take no account. His calculations are based on determinations of the maximum yield of organisms obtainable per unit amount of vitamin in laboratory pure culture; but it is the influence of the vitamin on the rate of growth, not on the final yield, which will be more relevant to marine ecology. In a natural environment a concentration of vitamin B_{12} (or indeed of any other nutrient) sufficient to support considerable cell-division may nevertheless be a limiting concentration, if the rate of cell-division so supported is only sufficient to compensate for the losses of cells due to other factors such as predation, sinking and the like.

The figures Droop uses for concentrations of vitamin B_{12} in ocean waters are those of Cowey[1]; but reference to Cowey's paper shows that they were obtained after subjecting filtered water to an extraction procedure in which the first stage is heating with cyanide. This procedure would be expected[2] to free the vitamin B_{12} from any combination with, for example, filter-passing cells, cell fragments and the sequestering substances ('binding factors') which are found in some protist culture liquors[3]. Cowey's values are therefore of total filtrable vitamin content. If, however, some of this vitamin was present in combined forms, the amounts of vitamin which were free and therefore certainly available for plankton nutrition would be less than the total amounts recorded by Cowey.

A further complication is that 'bound' vitamin B_{12}, though of no use to some plankton species, might be utilizable by others.

It seems to me that the sea's vitamin B_{12} should remain a subject of interest to investigators concerned with marine productivity; much more information, on this vitamin and on marine ecology in general, must be collected before any final conclusions can be drawn about the influence of vitamin B_{12} concentrations on life in the sea.

This work was aided by the Development Fund.

Vitamin B_{12} Distribution between Plasma and Cells

PUBLISHED values for vitamin B_{12} and blood dyscrasias are nearly all based upon values in serum[1]. Since B_{12} assays can be carried out without inhibition of the assay organisms by whole blood and without interference by colour[2-4], we investigated the distribution of B_{12} between plasma and the cellular elements of blood.

Citrated or heparinized blood from (*a*) healthy individuals, (*b*) patients with untreated pernicious anæmia, and (*c*) a patient with total gastrectomy was assayed with *Euglena gracilis* and *Ochromonas malhamensis* by methods outlined previously[2,3,5]. The pernicious anæmia patients were untreated at the time blood was drawn. The totally gastrectomized patient had been given B_{12}, but because serum-levels had been low his blood was included in this series.

The blood cells were separated from the plasma by centrifugation and the hæmatocrit values recorded. The cells were then washed six times with acid citrate glucose solution and resuspended in a volume of this solution equal to the original volume of whole blood. The plasma and blood cells were prepared for assay as described[5].

Table 1. VITAMIN B_{12} CONTENT OF PLASMA AND BLOOD CELLS
Vitamin B_{12} (μμgm./ml.)

Subject	State	Plasma (*P*)	Blood cells (*C*)	Total blood (calc.)* (*T*)	Hæmatocrit (*H*)
1. *H. B.*	Normal	620	76	380	44
2. *H. S.*	Normal	600	59	375	42
3. *I. P.*	Normal	320	88	210	47
4. *J. A.*	Pernicious anæmia, untreated	23	15	22	16
5. *A. S.*	Pernicious anæmia, untreated	32	15	30	13
6. *R. J.*	Gastrectomy	50	33	47	20

* Values for total blood are calculated from $T = \frac{(H\,C) + (100 - H)\,P}{100}$

As shown in Table 1, the plasma for normal subjects contains four to ten times more B_{12} than the cellular elements; in the patients with pernicious anæmia or total gastrectomy the plasma contains 1·5–2 times as much B_{12} as the blood cells. A comparison of the hæmatocrit values of the normal and pernicious anæmia groups with the corresponding cellular B_{12}-level, shows that both groups are not much different in B_{12} content per hæmatocrit unit; it is remarkable that cells survive at such low plasma B_{12}-level, although, of course, their number is reduced by lowered B_{12} supply. As for the proportion of B_{12} in the cells as compared with B_{12} in total blood, one finds percentages of 7–14 in the cells from the patients with pernicious anæmia and gastrectomy, while the values for normal whole blood vary from 7–19 per cent. Thus the number of cells in the circulation reflects the available vitamin B_{12}.

The high proportion of B_{12} in the cells of the pernicious anæmia group, as compared to B_{12}-levels in plasma suggests that B_{12} used for red cell formation and maturation is efficiently drawn upon even when the pool of the vitamin is severely depleted. The abnormal cytological picture in pernicious anæmia may be explained by there being enough B_{12} to initiate cell formation, but not enough for the cells to mature normally. Only plasma well supplied with B_{12} supports normal maturation in bone marrow and cells.

In pernicious anæmia the bone marrow competes with other tissues for the limited store of B_{12}. When nerve tissue becomes depleted of B_{12}, sub-acute combined degeneration of the cord ensues. Treatment of pernicious anæmia with folic acid may induce both a hæmatological remission and sub-acute combined degeneration of the cord[6]. This suggests that the small store of B_{12} is mobilized towards the bone marrow, alleviating its deficiency, but markedly aggravating B_{12} depletion in other tissues.

Plasma-levels do, then, reflect closely the vitamin B_{12} supply of the tissues, even though the blood cells from patients with pernicious anæmia do not contain substantially less B_{12} than normal cells if the hæmatocrit value is considered.

Changes in Cellular Nucleic Acids during Infection with Poliomyelitis Virus as studied by Fluorescence Microscopy

REMARKABLE similarities have been found between the biological properties of animal viruses containing ribonucleic acid and those of viruses containing deoxyribonucleic acid (such as bacteriophages). The question has thus been raised whether the mechanism of duplication of the two types of virus may involve common steps[1]. One possibility is that viruses containing ribonucleic acid have an intracellular deoxyribonucleic acid phase. With this point in mind, extensive cytochemical investigations of the changes occurring in the nucleic acids of cells infected by poliomyelitis virus have been carried out.

Monolayer cultures of monkey kidney cells grown on coverslips were infected with type 1 Mahoney virus in a concentration adequate to infect almost all the cells in half an hour. The virus release from these cells is known to begin between five and six hours after infection[2]. At various times after infection, specimens were collected and examined, either living or after methyl alcohol or Carnoy's fixation, and some also after freeze-drying. In all cases the samples were stained for 3 min. with diluted acriflavin (10^{-4} or 10^{-5} in weight in phosphate buffered saline, *p*H 7·4). After thorough washing and subsequent differentiation in 0·5 *M* calcium chloride, they were observed under the fluorescent microscope (cf. ref. 3).

The following observations were made. Normal uninfected cultures, or infected cultures up to 3 hr. after infection, show only a very faint fluorescence, dull green in the nucleus, reddish yellow in the nucleolus, faint red ochre in the cytoplasm. Three hours after infection a hazy greenish fluorescence appears in the nucleus. Four hours after infection the nucleus shows a bright green fluorescence, while the cytoplasm takes on a brighter red colour. The red fluorescent material shows a marked tendency to lump, and is discarded from the cells into the medium at this and subsequent hours as coarse granules and bigger clumps. Five hours after infection the bright green fluorescence of the nucleus disappears in more than 50 per cent of the cells; the nuclei appear empty except for the clearly visible nucleolus. The cytoplasm is mostly depleted of the red fluorescent material, and instead a bright green fluorescence is seen, at first as a ring around the nucleus and later spreading over the central part of the cell. Often a bright green, spherical body can be seen lying para-nuclearly, corresponding to the well-known acidophilic inclusion, described by different authors, in fixed and stained preparations.

The use of enzymes shows that the red fluorescence disappears after treatment with ribonuclease, and that the green fluorescence disappears or is greatly attenuated by the action of deoxyribonuclease; controls treated with the buffer solutions in which the enzymes were dissolved showed no changes.

The observations made on fixed and stained preparations confirm the finding of Reissig *et al.*[4], that the disappearance of the chromatin network in the nucleus is one of the earliest visible changes observed in cells infected with poliomyelitis virus.

The behaviour of fluorescence and the effect of specific enzymes suggest that a modification of the nuclear deoxyribonucleic acid is an early consequence of infection. The changes seen a little later in the cytoplasmic red fluorescent material would suggest changes in the cytoplasmic ribonucleic acid. The appearance of a green fluorescence sensitive to deoxyribonuclease in the cytoplasm suggests a marked alteration in the permeability of the nuclear membrane occurring 3–4 hr. after infection. This is supported by the finding that while the nuclear membrane is of normal appearance in living and frozen dried infected cells, it appears greatly distorted and wrinkled when fixed in methyl alcohol or Carnoy's fluids. It is likely that the wrinkling is produced by a quick loss of nuclear materials during fixation, secondary to the permeability changes.

The significance of the observed changes in deoxyribonucleic acid cannot be assessed at present. It is suggestive that the increased fluorescence of the nuclear deoxyribonucleic acid reveals an essential step in virus reproduction, since it is one of the first visible signs of infection. The subsequent migration of deoxyribonucleic acid to the cytoplasm may either indicate the migration of virus precursors in the same direction or may be a consequence of the alteration of the nuclear membrane and not primarily connected with the reproduction of the virus. A better understanding of the observed phenomena must await further work.

Details of this investigation, which was supported by a grant from the National Foundation for Infantile Paralysis, will be published elsewhere.

Pasteurella septica: the Occurrence of Type-Specific Polysaccharides containing Aldoheptose Sugars

Pirosky[1] has shown that strains of *Pasteurella septica* produce lipopolysaccharide antigens with similar properties to the endotoxins of certain other Gram-negative bacteria. We have isolated lipopolysaccharides from some strains of *P. septica* and studied their serological specificity in relation to the immunological status of the strains as measured by passive protection tests[2,3].

Strains of *P. septica* were grown by shake culture in tryptic meat broth at 37° C. for 2 days. Cells were harvested by centrifugation, dried with acetone, and crude lipopolysaccharide obtained from the dried cells (10–20 gm. amounts) by extraction with 45 per cent phenol[4]. Crude extracts, dialysed to remove phenol, were centrifuged at 100,000*g* for 4 hr. and the nucleic acid-free sediment suspended in water and dried from the frozen state.

Serologically active lipopolysaccharides were obtained in about 2 per cent yield from both a virulent, capsulated type V strain[3] (*P1/V/V*) and its avirulent variant (*P1/V/A*). The isolated materials were white powders, poorly soluble in water. An analysis of *P1/V/V* showed N, 2·5; P, 4·0 per cent; nucleic acid, not detected by absorption at 260 mμ. Both lipopolysaccharides were highly pyrogenic in rabbits but failed to kill them or mice or guinea pigs at a level of 500 μgm. Each material was precipitated at 1/125,000 dilution by an antiserum prepared in rabbits by the successive intravenous injection of heat-killed and live *P1/V/V* cells. Neither of the *P1/V* lipopolysaccharides precipitated strongly with a *P. septica* type I antiserum.

The reaction between the two *P1/V* lipopolysaccharides (1 mgm. amounts) and the anti-*P1/V* serum was followed by diffusion precipitin analysis in agar[5,6]. Each lipopolysaccharide gave a single, clear line of precipitation after 4 days development. The lines showed the reaction of identity both with each other and with one of the twelve lines which formed when live *P1/V* cells were examined against the same serum. Non-type-specific antibodies were largely removed from the *P1/V* antiserum by absorption with acetone-dried cells of a virulent type I strain (*P28/I/V*) and the absorbed serum was examined against *P1/V* lipopolysaccharide and live cells of representative strains from five different immunological types of *P. septica*. It was found that only the immunological type V strains possessed the *P1/V* lipopolysaccharide, this material being absent from strains of types I, II, III and IV. Heating of cells for 1 hr. at 100° C. did not prevent the formation of the lipopolysaccharide line of precipitation. Fig. 1,*A* shows the presence of lipopolysaccharide (*P*) and another thermostable, type-specific antigen (*S*) in a number of type V strains and their absence from a supposed type V strain, *P81/V/A*. A rough variant NCTC 5393 of unknown immunological type produced the *S* but not the *P* antigen, unlike its smooth parent NCTC 5394, which produced both. When the absorbed *P1/V/V* serum was further treated with purified *P1/V* lipopolysaccharide the line of precipitation normally given by type V cells was specifically suppressed (Fig. 1,*B*).

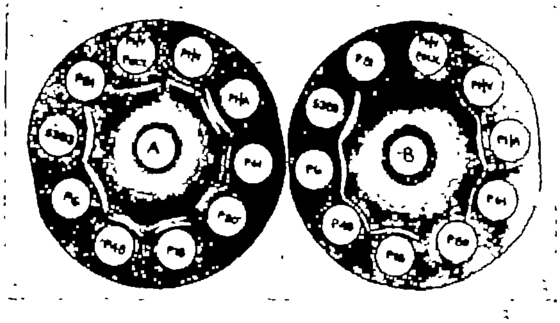

Fig. 1. Diffusion precipitin analysis of *Pasteurella septica* strains. Serum reservoir *A* contained *P1/V/V* antiserum absorbed with *P28/I/V* cells and *B* the same antiserum further treated with purified *P1/V* lipopolysaccharide. Antigen reservoirs contained *P1/V* lipopolysaccharide or cells of various type V strains. The lipopolysaccharide line is labelled *P* and a second thermostable type specific antigen *S*

Diffusion precipitin analysis was applied further to other types of *P. septica*. Live and heated *P. septica* cells of type I and type III were examined against antisera to types I, III and V, each absorbed with cells of heterologous type. The four type I strains examined possessed a common, thermostable antigen which was absent from types II, III, IV and V, and similarly, the five type III strains possessed a thermostable, type-specific antigen not found in types I, II, IV and V.

Aldoheptose sugars have been detected previously in polysaccharides isolated from *P. septica* (Davies, D. A. L., and Knox, K., personal communications). Examination by paper chromatography of neutralized acid hydrolysates of *P1/V* lipopolysaccharide revealed both an aldoheptose and glucosamine. (Hydrolysis for 18 hr. at 100° C. in 0·5 *N* sulphuric acid: chromatography solvent, butanol 3; pyridine, 2; water, 1·5; spray reagents, anisidine and the Ehrlich reagents.) The presence of aldoheptose was confirmed by the sulphuric acid–cysteine reaction of Dische[7]. The *P1/V* aldoheptose sugar behaved similarly to authentic D-glycero-L-mannoheptose on butanol–pyridine–water chromatograms; but it must be strongly emphasized, in view of the poor chromatographic separation of many aldoheptose sugars, that this is not a proof of identity.

A very poorly soluble lipopolysaccharide containing aldoheptose, glucosamine, and galactose has been obtained from a *P. septica* strain of unknown immunological type. When made soluble by ultrasonic treatment of aqueous suspensions this gave a single line of precipitation on diffusion plates with type I antiserum but no reaction with type V antiserum. An aldoheptose, glucosamine and galactose have also been found in polysaccharides obtained from type I and type IV strains. It seems probable, therefore, that in common with other members of the *Pasteurella* group (Davies, D. A. L., personal communication and ref. 8), aldoheptose sugars are of general occurrence in lipopolysaccharides produced by strains of *P. septica*.

The general composition and properties of the lipopolysaccharides described resemble those of the more fully characterized 'rough' lipopolysaccharide of *Pasteurella pestis*[8], although serological tests show them to be distinct. When these properties are considered in conjunction with the reported presence in strains of *P. septica* of endotoxins[1], it seems probable that the serological specificities we have described can be attributed to the lipopolysaccharide components of these substances. These specificities parallel the immunological type specificity established by passive protection tests[2,3], although, in view of the presence of more than one type-specific antigen (Fig. 1), it cannot be said that the lipopolysaccharide antigen is necessarily protective.

We are indebted to Dr. J. R. Hudson and Dr. R. D. Huck for *P. septica* strains of known immunological type, to Dr. D. A. L. Davies for *P. pestis* lipopolysaccharide, and to Mr. D. C. Hawkins for valuable technical assistance.

The Polyhedral Virus of *Prodenia litura* (Fabr.) (Lepidoptera : Noctuidae)

The occurrence of a polyhedrosis in larvæ of *Prodenia litura* (Fabr.) was first observed by Gough[1], Dudgeon[2], and Willcocks and Bahgat[3] in Egypt and was also reported by Crumb[4] from Europe and Caresche[5] from Indo-China. Recently, Abul-Nasr[6] found that this disease is a typical nuclear polyhedrosis. It occurs quite frequently in *P. litura* outbreaks in Egypt and causes heavy mortality in laboratory rearings. Because of the economic importance of the insect and the possible use of the virus for control purposes, it was decided to investigate the causative agent.

The *P. litura* larvæ used for this investigation were collected in the autumn of 1956 in the cotton fields near Cairo and Alexandria. Dead larvæ, mostly of the last stage, which showed the typical symptoms of polyhedrosis were dried in a desiccator and sent to Sault Ste. Marie. They were suspended in water for some weeks. After putrefaction, the suspension was filtered through fine orlon mesh and the insect remnants thoroughly washed to obtain a maximum yield of polyhedra. Since the sample consisted chiefly of heavily infected larvæ, it was easy to purify the polyhedra by differential centrifugation. About 130 mgm. of fairly pure polyhedra were obtained from 4·6 gm. dried larvæ.

The polyhedra are of irregular shape and vary in their diameter from about 1·2 to 3·2μ, the majority measuring about 1·8μ (Fig. 1). The standard method[7] is followed for the liberation and purification of the virus particles. The polyhedra (5 mgm./ml.) dissolve readily in a mixture of 0·008–0·01 *M* sodium carbonate and 0·05 *M* sodium chloride within about 3 hr. The impurities are removed by centrifugation for 5 min. at 4,000 r.p.m. (3,000*g*). The yellow and slightly turbid supernatant, consisting of polyhedral protein and virus, is spun at 11,000 r.p.m. (10,000*g*) for 1 hr., and the resulting yellow-white virus pellet is suspended in the same volume of distilled water after discarding the supernatant (polyhedral protein). The virus is sedimented again under the same conditions, and the final virus pellet is suspended in one-seventh of the original volume of distilled water. Approximately 20 μgm. virus particles were obtained from 1 mgm. polyhedra.

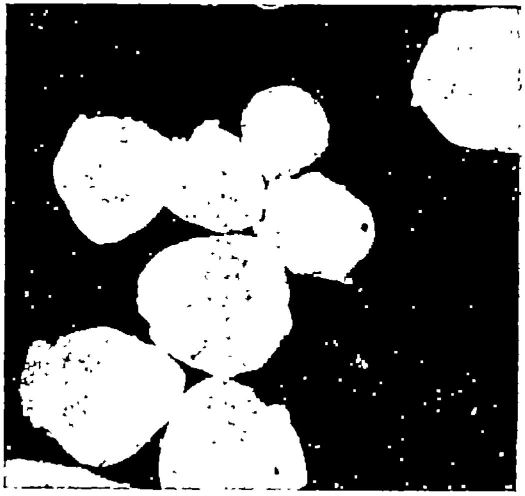

Fig. 1. Polyhedral bodies of *Prodenia litura*. (× 10,000)

Investigation in the electron microscope showed that the virus is rod-shaped and occurs frequently in bundles. It is a typical representative of classical polyhedral virus of the *Borrelina* group, and the name *Borrelina litura* is suggested. Numerous pictures revealed that this virus has all the typical morphological differentiations (developmental and intimate membrane, spherical stages, etc.) characteristic of this group (Fig. 2). There are comparatively few

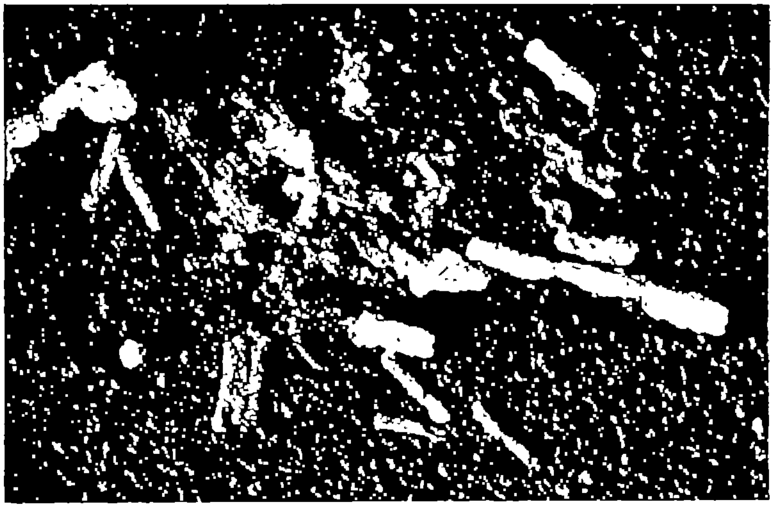

Fig. 2. Virus particles liberated from *Prodenia litura* polyhedra; several virus bundles are still surrounded by the developmental membrane, others have shed this membrane leaving single virus particles behind. Some of these disintegrate showing the flattened intimate membrane; one spherical developing stage is seen at upper right. (× c. 33,400)

single virus particles; the majority occur in bundles of several particles. The average dimensions of single virus rods still possessing the developmental membrane are about 320 ± 20 mμ × 100 ± 10 mμ. The diameter of most bundles is about 130 ± 10 mμ.

The condition of the larvæ did not permit us to determine whether this disease is a nuclear or cytoplasmic polyhedrosis. However, by analogy to other insect viruses, it is probable that it is a typical nuclear polyhedrosis. It is interesting that Abul-Nasr[6] describes polyhedra in the nuclei of mid-gut cells, which is unusual in Lepidoptera.

For technical reasons it was impossible to test the infectivity of the isolated particles, but the morphological characteristics leave no doubt that they are the causative agent.

One of us (B. F.) thanks the Ministry of Agriculture in Cairo, especially Dr. I. Bishara and Dr. M. Hafez, for their help in the *Prodenia* research problem.

In vitro Demonstration of Uterine Anaphylaxis in Guinea Pigs sensitized with Homologous Testis or Sperm

SPERM-IMMOBILIZING, agglutinating and precipitating antibodies have been detected in the sera of animals injected with sperm or testis[1]. Scrutiny of the literature revealed no studies which considered the possibility that injections of sperm or testis could induce an anaphylactic response. The present study was undertaken to examine this possibility.

Twenty-eight female guinea pigs were treated as follows: five females were injected intracutaneously in the nuchal region with an emulsion of homologous testis which was prepared by homogenizing testis tissue in an equal volume of saline, and incorporating the mixture in an equal volume of Freund adjuvant (paraffin oil, 'Arlacel A.' and *M. butyricum*)[2]. Five females were injected in a similar manner with an emulsion of washed epididymal guinea pig sperm in adjuvant. Eighteen females were selected at random from the colony, and nine of these were injected with the adjuvant alone, whereas the remaining nine were not injected.

Between 17–38 days after injection, the animals were killed, and their uteri were removed and suspended in a bath containing Locke's solution as the perfusion medium. The bath was maintained at 37° C. and was oxygenated. After a period of equilibration during which the rhythmic pattern of uterine contraction was recorded with a kymograph, 1 ml. of a suspension of epididymal sperm (which were washed twice with saline after removal from the epididymis and then resuspended in 4 ml. of Locke's solution) was added to the bath containing the uterine horn.

All the animals injected with testis or sperm were found to have uteri which reacted strongly to the challenge by contracting maximally within 30 sec. In five of the ten cases, the uteri remained contracted for the length of the period of observation (up to 4 hr.) despite flushings of the bath fluid (Fig. 1). By contrast, only transitory responses (dissipated within 5 min.) were found in five of the eighteen control animals (Fig. 2). All other controls were negative (Fig. 3).

The question may be raised whether the uterus of the sensitized animal reacts to sperm at copulation with a contracture type of response. If the contracture occurred at ovulation and was maintained for some time thereafter, fertility might be impaired, for implantation in a highly contracted uterus might be thwarted.

Numerous investigations have explored the possibility of immunizing females with sperm in order to confer infertility, but the results have been so contradictory as to impel Cushing and Campbell[3] to remark, "it may be stated with considerable assurance that the active immunization of females (including humans) against homologous sperm does not bring about sterility, even though antibody can be demonstrated in the serum". In the absence of convincing

Lack of Differential Radiation Effect on the Incorporation of Labelled Precursors into Deoxyribonucleic Acid

It has been reported that formate carbon-14 is preferentially taken up into deoxyribonucleic acid thymine by bone marrow cells *in vitro*[1,2]. This has been further confirmed by the 'thymidine dilution test'. Suspensions of human bone marrow cells were cultured *in vitro*[3], and the formate carbon-14 uptake was measured on high-resolution autoradiographs using the stripping film method on alcohol-fixed smears from such cultures[4]. The proportion of labelled cells ('per cent positive') was obtained by counting 250 cells, and the average count per cell by grain counts over 50 cells. The error-range of such counts is within ± 10 per cent. It was found that 0·18 mgm./ml. medium thymidine depressed formate carbon-14 uptake by 80 ± 11 per cent (seven experiments), while leaving adenine carbon-14 uptake unaffected (four experiments).

Comparison of adenine carbon-14 and formate carbon-14 uptake, using isomolar concentrations with the same specific activity, shows that very similar amounts of carbon-14 are taken up with both precursors (Table 1). Similar findings have been reported by other workers[5]. Since adenine carbon-14 and formate carbon-14 are in great excess in the medium (0·77 m.mole/ml.), if adenine carbon-14 was freely utilized for deoxyribonucleic acid guanine biosynthesis, one might expect a higher degree of labelling of deoxyribonucleic acid with adenine than with formate. The results in Table 1 indicate that in human bone marrow cells *in vitro* the utilization of adenine for guanine biosynthesis probably occurs very imperfectly. The slightly lower total grains per 100 cells in adenine carbon-14 cultures (by about 17 per cent) are probably due to the removal of some purines by the hydrolysis with *N* hydrochloric acid at 60° C. for 6 min.[6], which was necessary to remove nuclear ribonucleic acids. The latter are labelled to a similar extent as deoxyribonucleic acid[1].

Table 1. Comparison of Adenine Carbon-14 and Formate Carbon-14 Uptake into Deoxyribonucleic Acid in 16–21 hr. Cultures using Isomolar Media of same Specific Activity

Adenine carbon-14 (% +) –ve	Adenine carbon-14 Grains	Formate carbon-14 (% +) –ve	Formate carbon-14 Grains
58	25	62	45
64	50	55	40
56	40	73	50
52	40	65	50
66	50	53	45
50	50	74	50
58 ± 5	43 ± 8	64 ± 7	47 ± 4
Total grains/100 cells	2,494	Total grains/100 cells	3,008

There is some controversy in the literature as to the effect of radiation on the incorporation of different precursors of deoxyribonucleic acid. Harrington and Lavik[7] found that in rat thymus radiation depressed formate carbon-14 uptake into deoxyribonucleic acid, leaving adenine carbon-14 incorporation unaffected. Although other workers[8] did not confirm these results, Passonneau and Totter[9] found in chick embryos results similar to those reported by Harrington and Lavik. The suitability of the above experimental systems as regards normal biosynthesis has been queried[10] and therefore the problem has been investigated in human bone marrow cultures at the cellular level. The results in six experiments indicated that in this system both adenine carbon-14 and formate carbon-14 uptake were depressed to about the same extent by 1,000 rads of X-rays *in vitro*: adenine carbon-14 uptake by 68 ± 13 per cent, and formate carbon-14 uptake by 66 ± 17 per cent.

Comparison of the timing of the deoxyribonucleic acid synthetic period in the cell cycle using adenine carbon-14 or formate carbon-14 indicated that formate carbon-14 is utilized simultaneously with adenine for deoxyribonucleic acid biosynthesis during the approximately 12-hr. synthetic period. No indication was found for the existence of a presynthetic accumulation of low molecular weight precursors using formate carbon-14.

These results fail to indicate that irradiation would interfere with any particular step in synthesis of deoxyribonucleic acid. Inhibition appears to be the result of interference with some other mechanisms in the cell than the actual process of synthesis of deoxyribonucleic acid, as has been indicated by other studies[11,12].

Relation between Ribonuclease Activity and Ribonucleic Acid Content

The penetration of ribonuclease into ascites tumour and bone marrow cells has been described elsewhere[1]. It was shown that the biochemical effects induced in different types of cells by the enzyme seems to depend on the original level of ribonuclease in these cells. Landschütz ascites tumour cells, which are very poor in ribonuclease as compared with bone marrow cells, are very much more sensitive to its action[1,2]. These observations, together with the fact that the bone marrow cells, although they are richer in ribonuclease, are poorer in ribonucleic acid, have led us to determine the normal level of ribonuclease in different organs of normal animals, and to attempt to find if there is a relationship between the content of ribonuclease and that of ribonucleic acid in normal and cancerous tissues.

In the present work, organs are withdrawn immediately after killing the animals (mice or rats). They are thoroughly washed and minced in iced physiological serum, then homogenized. An aliquot is withdrawn for determinations of ribonucleic acid, deoxyribonucleic acid and protein, while another is extracted with $0{\cdot}15\,N$ sulphuric acid (final concentration) for 1 hr.

The first aliquot is extracted with 5 per cent perchloric acid and washed 10–12 times with ethanol/ether mixtures of increasing ether content. The dried sediment is hydrolysed in 10 per cent trichloracetic acid following the procedure of Schneider[3] or hydrolysed following the procedure of Schmidt–Tannhauser[4] using $0{\cdot}1\,N$ (instead of normal) sodium hydroxide. Content of ribonucleic acid and of deoxyribonucleic acid are then estimated by the orcinol and diphenylamine methods respectively or by measurement of ultra-violet absorption. Both procedures lead to similar results. The protein determinations are carried on the insoluble residues using the method of Lowry *et al.*[5].

On the second aliquot, protein determinations are also performed, and the centrifuged extract is used for determinations of ribonuclease. A sample of this extract is incubated at 25° C. in presence of polymerized yeast ribonucleic acid, prepared by the method of Kay *et al.*[6] and dissolved in $0{\cdot}2\,M$ acetate buffer of pH 5.

Samples are taken at 2, 15 and 30 min. and precipitated with an iced ethanol/perchloric acid mixture. After 15 min., the suspension is centrifuged, and the supernatant is analysed for nucleotide content by means of a Beckman ultra-violet spectrophotometer. The enzyme activity is estimated from the slope of the straight line obtained. This activity measurement includes, evidently, all the nucleolytic enzymes dealing with depolymerization of ribonucleic acid. Fig. 1 shows the results obtained in three different experiments (performed respectively on three mice two mice and one rat). The ribonuclease/protein and ribonucleic acid/protein ratios for eleven organs are indicated, with their respective standard errors.

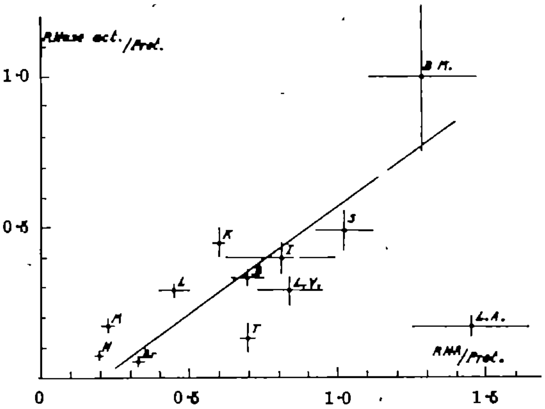

Fig. 1. Variation of ribonuclease/protein ratio versus ribonucleic acid/protein ratio for different tissues of the mouse or the rat. *H*, heart; *M*, muscle; *B*, brain; *L*, lung; *T*, testis; *B*, blood; *K*, kidney; *L.V.*, liver; *I*, intestine; *S*, spleen; *B.M.*, bone marrow; *L.A.*, Landshütz ascites

The results show that there is a significant correlation between content of ribonuclease and of ribonucleic acid for normal organs (significance of the regression line: $t_9 = 5{\cdot}35$, $P < 0{\cdot}001$). This relationship is an indication of the possible importance of the nucleolytic enzyme content for cellular metabolism, as already suggested by Roth[7]. The importance of the nucleolytic enzyme content in ribonucleic acid metabolism is now being tested with radioactive purine and pyrimidine precursors. According to the hypothesis of Brachet[8] and Caspersson[9] of a relation between ribonucleic acid and protein synthesis, it is conceivable that the nucleolytic enzyme-level in different tissues might be the pacemaker for the growth and the differentiation of the cells. In this respect, it should be noted that the mouse Landschütz ascites tumour occupies a very peculiar place in the graph: experiments are in progress to determine whether this is particular to that type of tumour or is a general characteristic of cancer tissues. Differences between the level of activity of enzymes of normal and cancerous tissues have recently been noted by Lewin[10] for xanthinoxidase and by de Lamirande[11] for different purine metabolizing enzymes.

Note added in proof. A recent publication by S. Brody (*Biochim. Biophys. Acta*, 24, 502; 1957) shows the existence of a similar correlation between ribonucleic acid and ribonuclease activities during the development of the human placenta.

Surface Alteration and the Agglutinability of Red Cells

IN the course of a study of the effects of formalin on red cells it was noted that formalin was capable of completely inhibiting the agglutinability of red cells by antisera without destroying the antigens of the cells.

Initially, the effect of concentration of formalin and length of treatment on the stability of red cells was examined. Various dilutions of formalin were made up in buffered saline and the solutions were adjusted to pH 7·3. Five per cent suspensions of washed human red cells were made in the formalin dilutions and stood for varying lengths of time at 25° C. The mixtures were centrifuged, and the formalin-treated red cells were washed four times with buffered saline (pH 7·3). It was observed that

Table 1. Agglutination of Type *A* Red Cells with Anti-*A* Serum after 24 hr. Treatment with Formalin

Concn. of formalin (Per cent)	Dilutions of sera 1:2	1:4	1:8	1:16	1:32	1:64	1:128	1:256	1:512
0	4	4	4	4	4	4	4	3	0
1	4	4	4	4	4	3	2	0	0
2	4	4	4	4	4	3	0	0	0
5	4	4	4	3	2	0	0	0	0
10	0	0	0	0	0	0	0	0	0
20	0	0	0	0	0	0	0	0	0

Maximum agglutination = 4.

with short periods of standing in formalin there was some hæmolysis on washing of the treated red cells, but after 24 hr. no hæmolysis was observed upon washing the cells. Agglutination tests were carried out by mixing dilutions of antisera with equal volumes of a 2 per cent cell suspension, incubating at 37° C. for 30 min., centrifuging the mixture and observing for agglutination by gently agitating the tube. The agglutinin titres observed with anti-*A* sera and type *A* red cells treated with various concentrations of formalin for 24 hr. at 25° C. are given in Table 1. It is observed that the lower concentrations of formalin decrease the agglutinability of the red cells while the higher concentrations suppress it. In view of these results treatment of red cells with 20 per cent formalin for 24 hr. at 25° C. was adopted as the standard treatment procedure in the work to be discussed.

The Coombs test was negative with formalin-treated red cells, as were attempts to effect agglutination by the addition of anti-rabbit globulin serum to the cells sensitized with Coombs serum or by the Coombs 'build up' technique[1]. Serum was absorbed by mixing one volume of packed red cells with one volume of serum at room temperature for 15 min. The results of an absorption experiment with type *A* red cells and anti-*A* serum are given in Table 2. It is observed that formalin-treated red cells removed the agglutinin. It was thought that formalin-treated red cells may in some way be removing the agglutinins non-specifically; however, this was ruled out by noting that type *B* formalin-treated red cells did not remove the agglutinins from anti-*A* sera (Table 2) and that type *A* formalin-treated red cells did not remove anti-*B* agglutinins. When the formalin-treated red cells that were used in the absorption experiment were thoroughly washed, mixed with an equal volume of buffered saline and heated at 56° C. for 15 min., the specific agglutinin was eluted.

Experiments were carried out with type *B*, *Rh* (*D*), and with periodate-treated cells[2] with identical results. Periodate ions render red cells panagglutinable and experiments were carried out with red cells treated with formalin before and after periodate treatment.

Table 2. Absorption of Anti-*A* Serum by Normal and Formalin-treated Red Cells

	Dilutions of sera 1:4	1:8	1:16	1:32	1:64	1:128	1:256	1:512
1. Unabsorbed sera	4	4	4	4	4	4	3	0
2. Serum absorbed with formalin-treated *A* cells	0	0	0	0	0	0	0	0
3. Serum absorbed with normal *A* cells	1	0	0	0	0	0	0	0
4. Serum absorbed with formalin-treated *B* cells	4	4	4	4	4	3	2	0

These results indicate that formalin acts in some manner on the surface of the red cell so as to inhibit the ability of the cells to be agglutinated, without having any apparent effect on the antigens that have been studied thus far. The mode of action of formalin in causing this effect is not known at present. The results suggest that in studying substances that are being tested for their effect on the antigens of red cells it is not sufficient to see whether or not such substances inhibit the agglutination of red cells. The destruction of the ability of the red cells to be agglutinated by their specific antisera may be due, as is the case here, to an alteration of the surface of the cell even though the antigen is not affected.

Recently a number of papers[3-5] have appeared describing red cells which are type *A* but which are weakly agglutinable or not agglutinated by anti-*A* sera. Red cells behaving in this manner have been assigned to a number of different new sub-groups of *A*, and the occurrence of such types of red cells is thought to be genetically controlled by a modifying gene. In one instance this property was noted to develop in the course of a disease. In view of the observations noted with formalin-treated red cells it is suggested that in some cases this behaviour of red cells may not be due to genetic differences but that this property may be acquired due to some alteration to the red cell surface *in vivo*. It would appear possible that changes in the surface of the red cells *in vivo* may alter the reaction with antisera. It has been noted that the surfaces of red cells treated with formalin when observed under the electron microscope[6] resemble those of cells from patients with diseases such as acquired hæmolytic anæmia in which changes in the surface of the red cells are thought to occur. It would be interesting to test the agglutinability of an individual's red cells over a period of time in health and during the course of various diseases to see if any change occurs. The detection of such changes, if they do indeed occur, may be of value in the diagnosis of and following the course of certain diseases.

This investigation was supported by a grant (*H*-1976) from the National Heart Institute, National Institutes of Health.

Intracellular Distribution of Catecholamines in the Brain

A survey of animal tissues carried out in this Laboratory[1] has shown that 3-hydroxytyramine is found more consistently and in higher concentration in the brain than in a number of other tissues. We have now studied the intracellular distribution of adrenaline, noradrenaline and 3-hydroxytyramine in the brain stem of the rabbit.

The tissue, homogenized in a solution of 10 per cent sucrose and 0·1 per cent sodium ethylenediamine-

Table 1. CATECHOLAMINES IN THE BRAIN STEM OF THE RABBIT

	Adrenaline (μgm./kgm.)	Noradrenaline (μgm./kgm.)	Hydroxytyramine (μgm./kgm.)	Dihydroxyphenylalanine (μgm./kgm.)
Homogenate, acidified immediately	89	320	776	0 (< 15)
Homogenate, acidified later*	85	306	824	
Coarse fraction	8·2	28·5	74	
Mitochondria	35·8	144	305	
Microsomes	4 5	16·6	42	
Supernatant	36·6	114	394	

*Homogenate acidified later: a sample of the sucrose homogenate was kept at 0° until the fractionating operations were completed and was then acidified.

tetraacetate (*p*H 7), was separated into four fractions at 0°: (1) a coarse fraction, obtained by centrifuging in an angle head at 300*g* for 5 min.; (2) a mitochondrial fraction, obtained by centrifuging at 10,000*g* for 20 min.; (3) a microsome fraction, obtained by adjusting the supernatant to *p*H 5·5 and afterwards centrifuging at 10,000*g* for 15 min.; and (4) the final supernatant fraction. All fractions were extracted with 0·1 *N* hydrochloric acid (final concentration). From these extracts catechols were isolated by adsorption on columns of alumina, further fractionated by chromatography on cation exchange resins and estimated fluorimetrically, as outlined in previous publications[1,2].

A representative result is shown in Table 1. Catecholamines were about equally divided between mitochondrial and supernatant fractions; the smaller amounts found in the coarse and microsome fractions were probably due to their contamination with the other two fractions. The total of the four intracellular fractions tallies well with the amounts found in the unfractionated homogenate. It is interesting to note that the three catecholamines occur in similar proportions in the different fractions. Whereas Montagu[1] found 3,4-dihydroxyphenylalanine in human brain, measurable amounts were not encountered in our analyses.

In the experiments described the rabbits were injected with iproniazid 1 hr. before death (100 mgm./kgm., intraperitoneally). The enzymic breakdown of catecholamines during fractionation, which is considerable otherwise, is thereby effectively inhibited.

Sodium Salt of the Directly Reacting Bile Pigment

THE composition of the bile pigment which shows direct van den Bergh reaction has been elucidated in recent studies[1–3]. This pigment is considered to be essentially a mixture of soluble salts of bilirubinyl-*bis*(β-D-glucosiduronic) and bilirubinyl-mono(β-D-glucosiduronic) acids. The preparation of the insoluble lead salt of the first of these acids has been reported in previous communications[3]. This precipitation renders possible a concentration of the pigment from aqueous alcoholic solutions of rough material.

Without decomposition, the lead salt of this pigment is insoluble in all solvents. For the present work a soluble pigment was obtained from its lead salt by conversion with cation exchanger (formaldehydic resin from phenolsulphonic and β-naphthalenesulphonic acids 'Katex *FN*') in Na+ cycle. This conversion was carried out without considerable decomposition, provided that no stronger acid, and especially no traces of alkalinity[4], are released from the resin. Such a conversion of salts with low solubility to soluble ones by means of cation exchanger has already been described[5]. In this case it was carried out by shaking a thick suspension of lead salt with a slurry of cation exchanger for about ½ hr. in an evacuated centrifuge tube. Usually about 1 ml. (= 0·4 gm.) of the resin is sufficient for 20 mgm. of bilirubin contained in the suspension. After removing the resin by centrifugation, the clear supernatant is quickly dried *in vacuo*.

The resulting amorphous material is collected in the form of dark-brown lamellæ, freely soluble in water, relatively soluble in methanol, less soluble in ethanol, insoluble in chloroform, ether and acetone. Colloidal particles of the lead salt which escaped conversion often become suspended owing to the high peptization properties of the pigment solution. These residues can be removed by precipitation or re-extraction with methanol. The resulting material gave by analysis 62 per cent pigments (bilirubin + biliverdin—55 per cent bilirubin), 28 per cent glucuronic acid, calculated on the weight basis as glucurone. Theoretically, the disodium salt of diglucuronide should yield 59·5 per cent pigment and 35·9 per cent glucuronic acid (on the above-mentioned basis)[4].

This product can be purified further by reversed phase chromatography as designed by Cole and co-workers[6] on columns arranged according to Billing[7] but on a larger scale (silicone-treated kieselguhr was generously given by Dr. G. H. Lathe of London). Instead of phosphate buffer in the system B^6 a 0·02-*M* acetate buffer of *p*H 5·6 was used in order to allow further precipitation of the lead salt from the methanolic eluate of a corresponding segment. Glucuronic acid was always detected although in quantities not identical with theoretical ones.

The assumption of a glucuronide character of this pigment is now supported by the recent biosynthetic experiments of Carbone and Grodsky[8], Lathe and Walker[9] and Schmid[10].

Selenomethionine in Enzymatic Transmethylations

In the past, biological interest in selenium has been centred around its toxic role as the cause of 'alkali disease' and 'blind staggers'[1] and as a source of industrial poisoning[2]. However, recent developments suggest a more important role for this element. Thus, it has been shown that selenium is an essential trace element for the rat[3] and is stimulatory, if not essential, for the growth of certain plants[4]. While inorganic selenium compounds are active in these cases, there is evidence that these inorganic selenium compounds are converted biologically into organic compounds, including the selenium analogues of cysteine[5], cystine, methionine[6] and cystathionine[7]. The structure of the essential selenium compound or compounds, therefore, remains to be established.

These results have stimulated interest in the metabolic role of selenomethionine. This analogue has been shown to support exponential growth of a methionine-requiring *E. coli* mutant, growth continuing for as long as one hundred generations on a methionine-free medium containing selenomethionine. Furthermore, micro-organisms grown under these conditions are capable of adaptive enzyme formation[5,8]. These results are of particular significance in that they demonstrate that proteins in which methionine is replaced by its selenium analogue have retained their functional integrity.

In the light of these findings, it was considered of interest to investigate the ability of selenomethionine to replace methionine in a biological reaction in which the sulphur atom of this amino-acid is functionally involved, namely, transmethylation. As is well established, an adenosine triphosphate-dependent enzymatic activation resulting in the formation of S-adenosylmethionine is a prerequisite for the enzymatic transfer of the methyl group of methionine. S-adenosylmethionine can act as a methyl donor to a suitable methyl acceptor in the presence of specific methylpherases[9]. It may be recalled that an essential feature in the activation reaction is the conversion of the sulphur atom from a thioether to a sulphonium configuration.

When selenomethionine was incubated with methionine-activating enzyme prepared from rabbit liver[10] or yeast[11], it was utilized as well as or better than methionine. Fig. 1 shows the results of an experiment in which methionine and selenomethionine are compared as substrates for the yeast methionine-activating enzyme. In the presence of excess pyrophosphatase the reaction can be followed by measuring the amino-acid dependent mineralization of the three phosphates of adenosine triphosphate and/or the formation of an adenosyl compound which, because of its cationic nature, is not adsorbed on 'Dowex-1' Cl. It can be seen that, in fact, selenomethionine is a better substrate for the yeast-activating enzyme than the natural sulphur analogue.

To test the ability of Se-adenosylselenomethionine to serve as methyl donor, the adenosyl compound formed from selenomethionine was precipitated as the crystalline trireineckate derivative, converted to the sulphate salt and afterwards incubated with guanidoacetic acid in the presence of pig-liver creatine methylpherase[9]. It was found that 0·28 μmole of Se-adenosylselenomethionine supported formation of 0·21 μmole of creatine by transmethylation while a control of 0·32 μmole of authentic S-adenosylmethionine gave a quantitative yield of creatine.

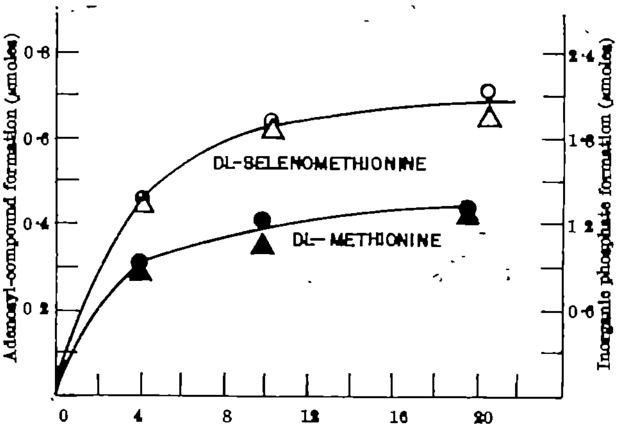

Fig. 1. Each vessel contained in a final volume of 0·5 ml.: *tris*(hydroxymethyl)aminomethane, pH 7·6, 75 μmoles; potassium chloride, 150 μmoles; magnesium chloride, 150 μmoles; adenosine triphosphate, neutralized with potassium hydroxide, 12 μmoles; reduced glutathione, neutralized with potassium hydroxide, 5 μmoles; substrate as indicated; an excess of yeast inorganic pyrophosphatase; 90 micrograms of methionine activating enzyme purified 250-fold from an extract of baker's yeast (ref. 11). Incubation was for 30 min. at 37°. The reaction was terminated by addition of perchloric acid and aliquots of the protein-free supernatant were used for determination of the inorganic phosphate (triangles) and adenosyl compound (circles) (ref. 10). A control was run without added substrate and the control value subtracted from the experimental. The stoichiometry of the reaction requires the mineralization of three moles of phosphate for each mole of adenosyl compound formed

The ability of inorganic selenium compounds to function as methyl acceptors in fungi and related species has been demonstrated by the studies of Challenger and his school[12]. The experiments reported here emphasize the ability of selenomethionine to replace its natural sulphur analogue as a substrate in two enzymatic reactions involved in biological transmethylation. Although in one instance it has been found that selenomethionine competes with its sulphur analogue[13], it may be postulated on the basis of the present evidence that the ability of seleniferous compounds to replace their sulphur-containing analogues is rather widespread.

We wish to thank Dr. Dean Cowie for use of a manuscript prior to publication and for the gift of a sample of selenomethionine which was originally synthesized by Dr. Alex Schrift.

Lactic Acid Formation and Carbon Dioxide Fixation

In an investigation, first into the composition of the internal atmosphere of successively lower regions of the plant body of *Equisetum limosum*, and secondly into the respiratory metabolism of the perennating rhizomes of this plant, a very interesting relationship between lactic acid formation and carbon dioxide fixation has emerged.

The plants studied grew in standing water, 1–1·5 m. deep with their perennating rhizomes extending in the bottom mud to a depth of up to 20 cm. This constituted a very markedly anaerobic environment. The internal atmosphere of the rhizome was rich in carbon dioxide and low in oxygen, the carbon dioxide concentration ranging between 5 and 8 per cent and the oxygen concentration between 2 and 8 per cent.

The rate of respiration of internodes of rhizome tissue was studied over a three-day period in various concentrations of carbon dioxide with an oxygen tension generally fixed at 5 per cent. Respiration was also studied in air and nitrogen. After the three-day period of respiration, the organic acids, α-keto acids and alcohol-soluble sugars were extracted from the tissue, separated chromatographically and estimated.

In Table 1 the amounts of lactic acid present in tissue allowed to respire in the dark at 25° C. under various gaseous conditions are given, together with the respiratory quotients obtained over the three-day respiratory period. It will be seen that a trace of lactic acid was present after respiration in a mixture of 2·5 per cent carbon dioxide and 5 per cent oxygen. No lactic acid was found in material allowed to respire in gas mixtures containing 3–12 per cent carbon dioxide with 5 per cent oxygen, nor in a mixture of 20 per cent oxygen and 3 per cent carbon dioxide.

The presence of a lactic dehydrogenase was demonstrated in a particulate suspension prepared according to the method of Davis[1].

The low respiratory quotients given by tissues in the presence of carbon dioxide suggested that carbon dioxide fixation may well have been occurring. This was investigated by making an autoradiograph of a chromatogram of the organic acids extracted from tissue that had been allowed to respire for 12 hr. in a mixture of 5 per cent oxygen and 7 per cent carbon dioxide containing a very small fraction carbon-14 labelled carbon dioxide. The autoradiograph gave a clear indication of carbon dioxide fixation, as there was labelling in malic, citric and succinic acids and in two unknown acids, one of which was tentatively identified as β-hydroxy butyric acid.

Thus the presence of lactic acid has been demonstrated only in tissues where it seemed unlikely that carbon dioxide fixation had occurred.

Table 1. Respiratory Quotients and Lactic Acid Content

Atmosphere			Respiratory quotient			Lactic acid γ per gm. F.W.
O_2 (per cent)	CO_2 (per cent)	N_2 (per cent)	1st day	2nd day	3rd day	
5·0	2·0	93·0	0·885	1·28	0·759	0·0
5·0	2·5	92·5	—	0·86	1·25	9·4
5·0	5·0	90·0	—	1·28	0·759	0·0
5·0	12·0	83·0	0·097	0·068	0·41	0·0
20·0	3·0	77·0	1·18	0·616	0·404	0·0
Air			0·865	0·760	0·669	41·5
3·5	0·0	96·5	1·23	1·11	1·20	31·0
0·0	0·0	100·0	—	—	—	77·5
0·0	5·0	95·0	—	—	—	40·0

Carbon dioxide fixation, whether by the malic enzyme as demonstrated by Conn *et al.*[2] or by a modified Wood–Werkman reaction described by Wood[3] and Utter[4] depends upon the β-carboxylation of pyruvic acid. It may well be, therefore, that where carbon dioxide fixation occurs there is a competition for pyruvic acid, by the processes of lactic acid formation and carbon dioxide fixation. There is, however, a second possibility, for Ochoa *et al.*[5] have demonstrated a coupled process of lactic acid oxidation and carbon dioxide fixation in pigeon-liver extracts.

$$\text{Malate} + \text{TPNox.} \underset{\text{Malic enz.}}{\overset{\text{Mn}^{++}}{\rightleftharpoons}} \text{Pyruvate} + CO_2 \ \text{TPN red.}$$

$$\text{Pyruvate} + \text{TPN red.} \underset{\text{Lactic dehyd.}}{\rightleftharpoons} \text{Lactate} + \text{TPNox.}$$

$$\text{Sum.} \quad \text{Malate} \overset{\text{Mn}^{++}\ \text{TPN}}{\rightleftharpoons} \text{Lactate} + CO_2$$

Korkes *et al.*[6] have demonstrated an essentially similar DPN specific malic enzyme/lactic dehydrogenase system in *Lactobacillus arabinosus*.

In general ecology of such a plant as *Equisetum*, it would plainly be of value if it possessed a mechanism whereby the two processes of lactic acid formation and carbon dioxide fixation competed for pyruvic acid. It would be equally important if there existed a TPN- or DPN-linked dismutation between malic acid and pyruvic acid through the combined action of the malic enzyme and the lactic dehydrogenase system. The fixation of respiratory carbon dioxide conserves the carbon of the rhizome, maintaining the levels of the organic acids, and if, as suggested, the process is linked to lactic acid oxidation, it would prevent the build-up of that fermentation product.

This work, which was carried out in the Department of Botany, University of Liverpool, under the supervision of Mr. D. A. Coult, will be reported in full elsewhere. It is a pleasure to acknowledge my indebtedness to Mr. D. A. Coult and Prof. N. A. Burges for their interest in this work and to Dr. W. O. James of the Department of Botany, University of Oxford, for his interest and kindness in giving me the facilities of his laboratory in which to learn the necessary chromatographic techniques. I am grateful to the Department of Scientific and Industrial Research for financial assistance.

Narcotic Activity of Optical Enantiomorphs of Methylpentynol

The optical resolution of *dl*-3-methylpent-1-yn-3-ol was achieved for the first time by one of us[1] some two years ago, and it seemed of interest to determine whether the narcotic activity of the optical antipodes differed, in spite of the contrary finding in the barbituric acid series. The criterion of narcosis was abolition of the righting reflex in female mice.

Racemic methylpentynol and its (+)-enantiomorph[1] were administered orally to groups of thirty-five mice at two dose-levels (506 and 338 mgm./kgm.) and the two results were compared 1 hr. after dosage. *dl*-Methylpentynol showed sixteen and three animals narcotized compared with seventeen and three for (+)-methylpentynol on the two doses. A somewhat impure sample of (−)-methylpentynol showed a slight diminution in activity in a group of fifteen mice, which was not significant in view of the above result.

A contemplated extension of the work to certain optically active esters of methylpentynol was therefore abandoned.

It is of interest to note that the *dl*-hydrogen phthalate, prepared in the course of the above work, was completely without effect, presumably owing to the very slow rate of hydrolysis *in vivo*.

We wish to thank Mrs. I. M. Weaver for the biological work involved.

Effects of Methylene Blue added to a Low Fat Diet in the Mouse

Dam and co-workers[1] have studied the effect of methylene blue added to various diets in the rat, and suggested that the drug can perform some of the functions of vitamin E. Dealing with young rats, they described an inhibition of growth; but no organ appeared to be especially affected.

We studied, in the mouse, the effect of the addition of methylene blue to a synthetic diet with a low fat content.

The composition of the diet was: complex-B free casein, 20 per cent; sucrose, 74·5 per cent; salt mixture, 5 per cent[2]; vitamins[3] and 0·5 per cent arachis oil. The α-tocopherol content was 150 mgm. per kgm. of diet. The methylene blue concentration was 0·126 per cent. The food was stored at 0° C.

The mice were from the colony at the Faculdade de Medicina de São Paulo. Both food and water were changed daily and given *ad libitum*. The animals were killed after 30 days. They were immediately dissected and the organs weighed on a torsion balance to the nearest 0·2 mgm. Groups of ten or more animals were used.

Table 1. Effect of Methylene Blue on the Body and Organ Weights of Adult Male and Female Mice

No. of animals in group			Body-weight	Spleen	Seminal vesicles	Testicles	Adrenals
Male	Control	10	29·5±0·6† (25·1)‡	260±22·0§	310±17·3	580±17·0	20±1·9
	Methylene blue	11	29·0±0·5 (23·5)	790±97·0	170±11·2	590±20·0	18±1·9
					Uterus and ovaries		
Female	Control	10	26·7±0·9 (20·6)	520±62·0	240±35·0		42±2·5
Female	Methylene blue	10	25·3±0·6 (19·3)	790±66·0	230±40·0		47±3·3

† Mean final weight in gm. ± S.E. of mean $\left(\sqrt{\frac{d^2}{n(n-1)}}\right)$

‡ Mean initial weight in gm.

§ Mean weight in mgm. per 100 gm. of body weight ± S.E. of mean.

Table 2. Effect of Methylene Blue on Body and Organ Weights of Male Mice with an Initial Weight of 14 gm.

No. of animals in group		Body-weight	Spleen	Seminal vesicles	Testicles
Control	10	26·2±0·8† (14·4)‡	328±30·0§	271±15·0	606±15·0
Methylene blue	11	18·3±1·2 (14·0)	3,924±224·0	93±22·0	650±49·0

†, ‡, §, As in Table 1.

In both sexes the body-weight was not affected when the initial weight was about 20 gm., but the spleen became very heavy. This is more evident in the male, in which this organ is normally lighter than in the female (Table 1).

There was a reduction in the growth-rate of the males with an initial weight of 14 gm., but the effect of the drug on the spleen was the same (Table 2).

In the males of both groups there was a reduction in the weight of the seminal vesicles (Tables 1 and 2). It is obvious from the results of the heavier group that this effect is not related to any inhibition of growth.

These effects seem to be restricted to the mouse. We were unable to detect them in the rat or the guinea pig even though there is a distinct change in the colour of the spleen.

The animals were active and healthy during the experiment. There were no indications of infection due to the blockage of the spleen.

We have not studied systematically the vaginal smears of the female group.

In castrated male mice methylene blue does not change the effect of the testosterone propionate on the seminal vesicles. These results suggest further study of the action of the drug on the testicular and hypophyseal functions of the mouse before any definite conclusion can be reached.

I acknowledge the technical assistance of Miss A. Ambrogi and Miss M. A. de Oliveira and the Conselho Nacional de Pesquisas for partial support.

Occurrence of Periodic Acid-Schiff Positive Material in the Pituitary of the Parrot Fish, *Pseudoscarus guacamaia*

DURING the course of investigations into the histochemistry of fish pituitaries, the distribution of periodic acid–Schiff positive material[1] was noted in the parrot fish, *Pseudoscarus guacamaia*. Whereas in mammalian pituitaries periodic acid–Schiff positive material is associated only with basophils (aniline-blue positive after Heidenhain's 'Azan' procedure), namely, the gonadotrophs and thryotrophs[2], in *Pseudoscarus* the mid-glandular region of the adenohypophysis has two types of acidophils, one of which is strongly and uniformly periodic acid–Schiff positive and the other negative. This large polygonaly shaped periodic acid–Schiff positive acidophil of *Pseudoscarus* stains a deep orange after the Gomori aldehyde–fuchsin orange *G* method for the demonstration of neurosecretory material and is carminophilic after treatment with Heidenhain's 'Azan' stain. In addition to this type of cell, two types of basophils are present in the mid-glandular region which are periodic acid–Schiff positive as in mammals and other teleost fish. Furthermore, although some of the periodic acid–Schiff positive basophils stained selectively after aldehyde–fuchsin as in other teleosts[3], the periodic acid–Schiff positive acidophil gave a negative aldehyde–fuchsin reaction. It would appear, then, that in this fish, unlike mammals, a carbohydrate containing hormone is possibly produced by cells which are 'acidophilic' after application of the conventional staining procedures.

Neurosecretory material in the neurohypophysis of *Pseudoscarus* gives a very positive reaction after aldehyde–fuchsin treatment. However, this neurosecretory material is not periodic acid–Schiff positive. This appears to conform with observations made on the neurohypophysis of other species of fish in which there is little or no carbohydrate-containing material that can be identified with the neurosecretion. Schiebler[4], however, reports periodic acid–Schiff positive material having the same localization as Gomori neurosecretory substance in the pike (*Esox lucius*), and has suggested that neurosecretion is probably a complex of glycolipoprotein. Observations made on the neurosecretory substance of *Pseudoscarus* and some other teleosts have given results which are more in accord with those of Howe and Pearse[5], who regard the neurosecretory substance as not containing lipid or carbohydrate material and being protein or polypeptide in character.

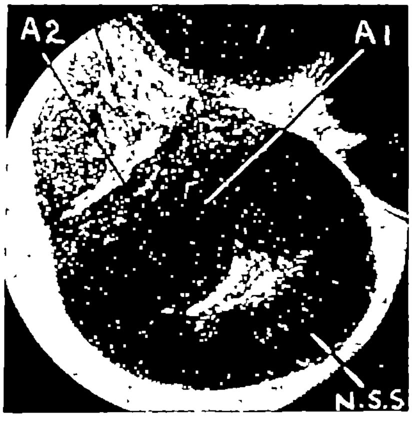

Fig 1 Longitudinal section of the pituitary of *Pseudoscarus* (× c. 215) after staining in orange *G* and aldehyde–fuchsin showing dark orange acidophils, *A*1; yellow acidophils, *A*2; and neurosecretory substance, N.S.S.

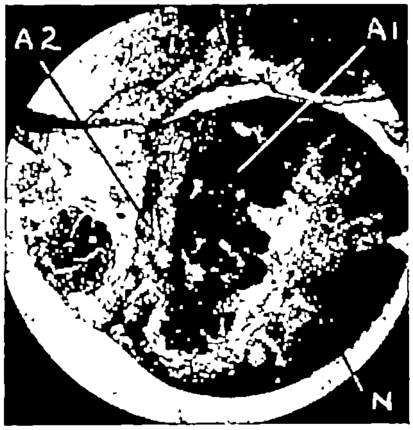

Fig. 2. An adjacent section to that of Fig 1 after periodic acid–Schiff treatment showing that only the *A*1 acidophils are positive. *N*, neurohypophysis.

Soil Transmission of Beet Ringspot Virus to Peach (*Prunus persica*)

ALTHOUGH few plant viruses are known to be soil-borne, recent studies have shown that such viruses are present in many localities in eastern Scotland[1-3], and it was suggested that they are probably much more generally distributed than has hitherto been suspected. The soil-borne viruses found in Scotland appear to have a very wide host-range, and one of them, beet ringspot virus, has been isolated from many species of herbaceous plants, including sugar beet, potato, turnip, wheat, oat, strawberry and many weeds[3]. The results reported below show that this virus is also soil-borne to peach, a woody species, and that the virus can be readily transmitted by mechanical inoculation from peach to herbaceous plants.

In April 1956, twenty-five peach seedlings were planted in pots of soil which was collected from a field where beet ringspot virus occurred: the pots were kept in an insect-free glasshouse. Symptoms first appeared on seven plants in April 1957, when the dormant buds started to grow. However, one out of fifteen seedlings planted in similar soil in April 1957 showed symptoms within four weeks. Usually only a proportion of the buds on each diseased plant produced symptom-bearing leaves. These leaves had yellow blotches centred on the leaf midrib or lateral veins and often extending along them. Circular translucent areas also appeared in the laminas of some leaves as they unfolded and these later broke away from the expanding leaf blades, became brown and fell out, leaving 'shot-holes'. Most of the diseased shoots grew only slowly.

Viruses, afterwards identified as beet ringspot virus by plant-protection tests in White Burley tobacco and by serological tests[3], were readily isolated from each diseased tree by mechanical inoculation of leaf extracts to *Chenopodium amaranticolor* Coste and Reyn., *Petunia hybrida* Vilm. and cucumber plants: the symptoms in these hosts were typical of beet ringspot virus. The numbers of local lesions produced by leaf extracts from different peach plants were 100–212 and 27–160 per inoculated leaf of *C. amaranticolor* and *P. hybrida* respectively. Beet ringspot virus was isolated only from leaves with symptoms: no virus was detected by inoculations from the eighteen plants that did not show symptoms or from control plants grown for the same period in steam-sterilized potting compost.

The symptoms in peach seem very like those caused by peach yellow bud mosaic virus in California[4]. This virus has also been transmitted by mechanical inoculation to plants of other species[5], and there is evidence that it also is soil-borne[6]. It therefore seems possible that beet ringspot and peach yellow bud mosaic are the same or closely related viruses.

Tomato black ring[7] and potato bouquet[8] are two other viruses which seemed to have properties similar to those of beet ringspot virus, and experiments have shown that there is a relationship between them. As these viruses have been found in England, Germany and Scotland, respectively, there is now good evidence that viruses of this type are fairly widely distributed.

This is thought to be the first record for western Europe of the natural mode of transmission of a virus in a fruit-tree species.

Blindness in Early Summer Cauliflower

Wiebosch *et al.*[1] distinguished two forms of blindness in cauliflowers, namely, common blindness, where there is a sudden transition from normal development to complete blindness, and 'whiptail' (not due to molybdenum deficiency), where the leaves are malformed and small swollen 'stem organs' are produced in the centre of the plant. These workers suggested that both forms of blindness may be caused by a period of low temperature during the early stages of growth. A similar suggestion has been made by Smith[2]. Recently, Mounsey-Wood[3] found that blindness was associated with frost during the early growth of the crop, and suggested that low temperature when the seedlings were at a certain stage of development was likely to cause blindness. Evidence supporting this hypothesis has now been obtained at this Station.

Table 1

Period of low temperature treatment	Mean No. of leaves initiated before low temperature treatment	Effect of treatment	
		Percentage of plants with common blindness	Percentage of plants with partial blindness*
Feb. 8–22	3·2 ± 0·4	6·7	10·0
Feb. 23–March 8	4·8 ± 0·8	6·7	20·0
March 8–21†	7·3 ± 0·8	16·7	43·4
March 22–April 5	10·8 ± 0·8	6·7	6·7
Control (no low temperature)	—	0	3·3

* Termed 'whiptail' by Wiebosch *et al.* (ref. 1).

† The percentage of plants with blindness resulting from this treatment was significantly greater ($P < 0{\cdot}01$) than that from the other treatments.

Seed of the cauliflower variety Finneys 110, which is not normally susceptible to blindness, was sown on January 24. At different stages of growth, batches of thirty young plants were subjected to a temperature of 33 ± 2° F. for a period of fourteen days in a refrigerated cabinet which was illuminated artificially at an intensity of approximately 200 ft.-candles for the natural day-length. Except during the cold treatment period the plants were grown under conditions where the temperature did not fall below 45° F., until they were planted in the field on April 9. As a precaution, the plants were watered with sodium molybdate solution to prevent blindness from being caused by a deficiency of molybdenum[4].

The results obtained under the conditions of this experiment indicate that plants of this variety were particularly sensitive to a period of low temperature at a stage of development when approximately seven leaves had been initiated, as revealed by apical dissection.

Low temperature treatment before or after that stage caused blindness to a lesser extent.

Further work on this subject is proceeding, and a detailed account will be published elsewhere.

Isolation of *Leptotrichia buccalis* and *Fusobacterium* Species from Oral Material

Considerable difficulty has been experienced by many workers in distinguishing between strains of *Leptotrichia buccalis* (Trevisan) and species of *Fusobacterium* (Knorr).

Bøe and Thjøtta[1] suggested that many of the organisms described by Spaulding and Rettger[2], Hine and Berry[3] and other workers as members of the genus *Fusobacterium* were in fact strains of *Leptotrichia*. These workers also cite Nieber[4] as having difficulty in separating strains of *Leptotrichia* from *Fusobacterium* species. The work of Jackins and Barker[5] on the metabolism of *F. nucleatum* (Knorr) and *F. plauti-vincenti* (Knorr) showed that these two organisms, although placed in the same genus, differ considerably in their metabolism and their Gram-staining reaction. This latter organism, which is called *F. dentium* by Hine and Berry, is believed by Bøe and Thjøtta to be identical with, or closely related to, *Leptotrichia buccalis* (Trevisan). This view is also held by Hamilton and Zahler[6].

Work carried out in this laboratory has shown that it is possible to distinguish between strains of *Leptotrichia* and *Fusobacterium* by their sensitivity to dyes and antibiotics. Use has been made of this observation in devising selective media for the isolation of these organisms from the mouth.

Experiments were carried out on a number of dyes to test their selectivity. The dyes were added to a basal medium containing: Proteose peptone ('Difco'), 1 per cent; yeast extract ('Oxoid'), 0·1 per cent; 'Lab Lemco', 0·3 per cent; glucose, 0·5 per cent; soluble starch ('Analar'), 0·2 per cent; sodium nitrate, 0·1 per cent; cysteine hydrochloride, 0·05 per cent; and disodium hydrogen phosphate, 0·5 per cent. The constituents were dissolved in distilled water and the medium adjusted to *p*H 7·6. All experiments were carried out in McIntosh and Fildes jars filled with an atmosphere of hydrogen containing 10 per cent carbon dioxide, and incubated at 37° C.

The dye ethyl violet (Gurr's 'Michrome' brand), in the presence of a number of antibiotics, was found to be selective for isolating strains of *Leptotrichia* and *Fusobacterium* from the mouth. The concentration of dye used was one part in fifteen thousand to which the addition of either 15γ/ml. neomycin sulphate, 20 γ/ml. streptomycin sulphate or 0·001 mgm./ml. of bacitracin was found to be equally effective. The dye and the antibiotic were added aseptically to the medium immediately before use. Increasing the concentration of bacitracin to 0·1 mgm./ml. resulted in pure growth of *Fusobacterium* (Knorr); strains of *Leptotrichia* were inhibited. It was possible to isolate solely strains of *Leptotrichia buccalis* (Trevisan) by adding to the dye-containing medium 0·05 mgm./ml. of sulphathiazole. Lower concentrations of sulphathiazole permitted the isolation of both *Fusobacterium* and *Leptotrichia* species.

A New Species of Coccidium (*Eimeria rissae* n.sp. Eimeriidae, *Sporozoa*) from the Kittiwake, *Rissa tridactyla tridactyla* (L.)

Eimeria rissae n.sp. was obtained from the small intestine of a kittiwake which had been sent to us as a representative of a number of sick and dying kittiwakes from the coast of Wales.

Post mortem examination revealed that, in addition to the following parasites, *Seuratia shipleyi*, *Prosthorhynchus* (?) *linearis* and some immature echinostomes which were present in small numbers, an extremely large number of unsporulated oocysts was found in the duodenum. In view of the number of oocysts and the concomitant evidence of enteritis, death was ascribed to coccidiosis. So far as can be ascertained, no previous record of coccidia in the kittiwake has been made, and since the present species could not be identified with that of coccidia from other hosts we propose to recognize it as a new species, and to name it *Eimeria rissae*.

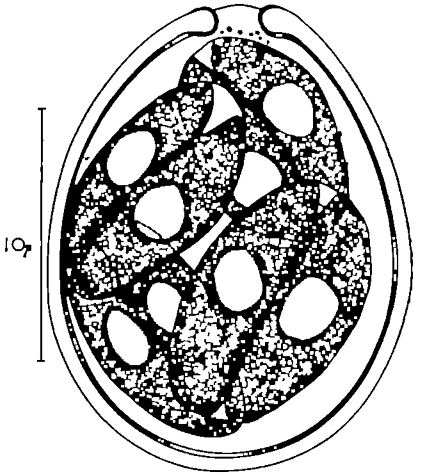

Fig. 1. Oocysts of *Eimeria rissae*. Lateral view of sporocysts, the sporocystic residual body omitted (camera lucida drawing)

The description of the oocyst is as follows. Slightly ovoid in shape with a distinct micropyle at the narrower end (2µ in diameter); oocyst wall consists of an outer thick wall (0·6µ in thickness) and an inner thin wall. The wall is distinctly thickened around the micropyle. The colour of the oocyst is very faintly yellow. Mean size, 13·6µ × 19·07µ; range, 12·1–15·4µ × 17·6–22µ. Sporulation time at room temperature (about 22° C.) is two days. Sporozoites lie side by side with a relatively large vacuole centrally placed. A large sporocystic residual body is present, roughly crescentic in shape and lies at the pole of the sporocyst filling half the diameter of the sporocyst when this is viewed end-on. No oocystic residual body is present, but numerous polar granules occur. These vary in number, sometimes as few as three large granules are present, and frequently up to twenty small granules are seen.

An attempt was made to transmit the infection to domestic chickens. Four week-old chickens were

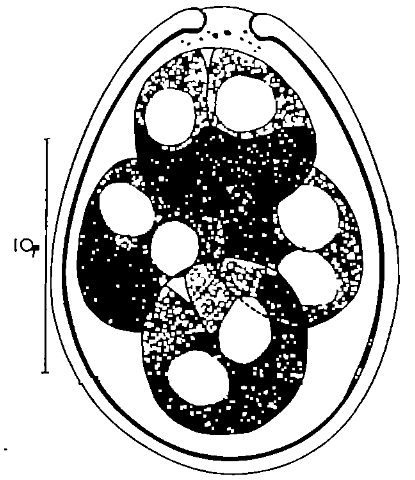

Fig. 2. Oocyst of *Eimeria rissae*. End-on view of sporocysts to show the marked sporocystic residual body (camera lucida drawing)

fed large numbers of sporulated oocysts, and the chickens were killed at intervals of three days commencing five days after the infection. No evidence was found to suggest that an infection was created.

This appears to be the first record of a member of the genus *Eimeria* from the kittiwake. It was kept in mind, however, that this might not be primarily a parasite of the kittiwake. Two sources of infection or contamination might be applicable, namely, acquisition from fish and from other birds, particularly sea-birds.

Of the *Eimeria* recorded from fish, there are no species which compare with the morphological features of *E. rissae*.

Transmission from other birds is a possibility, but since the species failed to set up an infection in chickens, it is probably not one of the *Eimeria* sp. from domestic poultry. The check list of Pellerdy[1] and the more extensive list of Becker[2] mention no *Eimeria* species in the family Laridae other than *Eimeria meservi* in Forster's Tern (*Sterna forsteri*), while in other families of sea birds *E. urnula* has been recorded in the cormorant (*Phalacrocorax carbo lugubris*)[3] and *E. roscoviensis* in the shag (*P. aristotelis aristotelis*)[4]. None of these has been recorded as occurring in birds in Britain, and, furthermore, with the exception of *E. urnula*, none agrees in size with *E. rissae*. Hoare[3] gives a range of 17·6–23·2μ × 12·8–13·6μ for *E. urnula*, but the shape of the oocyst and the character of the sporocysts differ from those of *E. rissae*.

We are of the opinion that sea-birds have been neglected from the point of view of coccidial infection. This is evident from perusal of the check list of Becker[2], where only three species are recorded from sea-fowl compared with the extensive records in mammals and other vertebrates. A more extensive and intensive study would, no doubt, reveal many hitherto unrecognized species.

We acknowledge financial assistance from the administrators of the H. E. Durham Fund, King's College, Cambridge, for this work, which is part of a wider survey of disease in the wild fauna of Great Britain.

The Rabbit Ductus Arteriosus

THE ductus arteriosus differs structurally and functionally from other large arteries. It is almost devoid of elastic tissue, and its smooth muscle fibres have a specific disposition[1,2]. In the rabbit, fine nerve fibres ending in relation to the muscle, as well as sensory type endings, have been described[3].

Recently, the rabbit ductus arteriosus has been studied after treatment by a modification[4] of Koelle's[5] technique for the demonstration of cholinesterase. The essential points of this variant are that the tissue is first fixed in formol-saline; incubation is then carried out in acetyl- or butyryl-thiocholine substrates which contain a high concentration of sodium sulphate, and are also buffered to an acid pH.

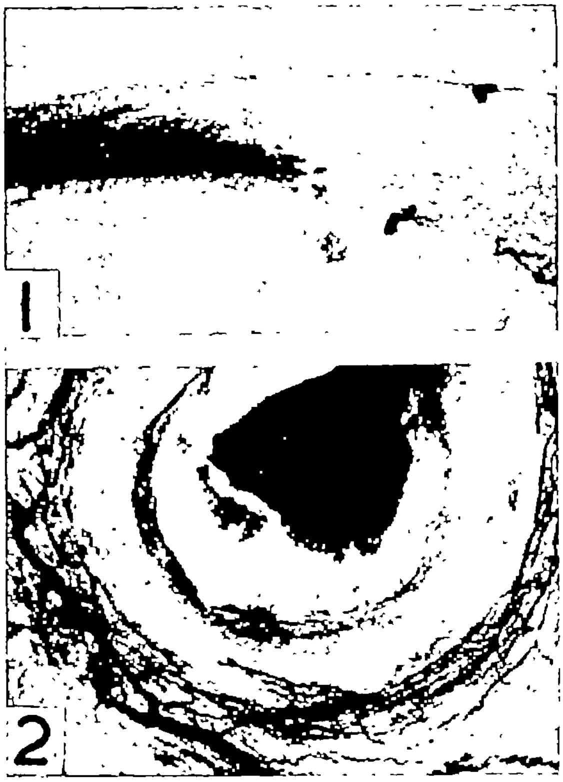

Fig. 1. 1, Longitudinal section of the junctional region between ductus arteriosus (on right) and aorta (left), showing the strongly positive cholinesterase reaction of aortic smooth muscle. The endothelial surface is along the upper edge of the section (× 83) 2, Transverse section (200μ) of ductus. A blood clot lies in the lumen. Cholinesterase-positive nerve fibres form a net in the adventitial zone of the wall, and some extend into the outer muscle layer (× 95)

Thick frozen sections and whole-thickness preparations were examined. It was found that the smooth muscle of the ductus differs histochemically from that of the pulmonary trunk and aorta. When incubated in a substrate of pH 5·6 it gives a negative reaction for cholinesterase, while that of the other two vessels is strongly positive. This contrast is especially marked in sections cut along the length of the ductus; at its junction with each of the other large trunks a well-defined boundary between the negative and positive muscle can be observed (Fig. 1,1).

Sections show a rich plexiform network of nerve fibres lying in the adventitial zone of the ductus wall (Fig. 1,2). A few small fibres penetrate the outer part of the muscle layer, and appear to end by branching. It is, however, difficult to be certain that this appearance is due to true nerve endings, and not simply to parts of the nervous network lying within the muscle layer.

Whole-thickness preparations of the ductus wall incubated as above and viewed from the endothelial surface show a network of nerve fibres with no obvious discrete endings. These fibres, although lying in the outer parts of the ductus wall, can be readily seen through its thickness on account of the negative cholinesterase reaction of its muscle.

These preliminary findings indicate that most of the ductus muscle is not in intimate contact with nervous elements. The negative cholinesterase reaction of this muscle, in contrast to the positive reaction in that of the other vessels, readily demonstrates the extent of the ductus tissue. This histochemical differentiation is another distinctive property of the ductus, which is already known to differ in structure and function from other large arteries.
